Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 38.0°

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, December 30, 10 a.m. Bar. 29.4. Temp. 50°. Weather Wet.

1925.

GARDENERS have every reason to be satisfied with their results in the past year; crops generally have been good—much better than they promised early in the season; horticultural societies have carried out successful programmes and organised shows that have been well attended; the special floricultural societies continue to make headway; plenty of novelties have been forthcoming and progress has been maintained in all branches of our craft. No event of outstanding importance took place in 1925, but it must be remembered that the Chelsea show alone is of sufficient magnitude and importance to attract visitors from all parts of the world and this show is now probably equal to many of the international exhibitions of the past. Those at York, Shrewsbury, Cheltenham, Birmingham, Brighton and the more important ones in Scotland are fast regaining their pre-war importance, whilst the marvellous success of the new Southport exhibition proves that the day of the flower show is by no means over and that success may be achieved if the organisers are men of vision and prepared to learn from the successes and failures of others. The meetings of the Royal Horticultural Society have been well attended and the exhibitions in connection with them as interesting as ever. Apart from the fortnightly meetings and the Chelsea show, the special exhibitions at Holland Park Hall, the vegetable show, fruit show, Orchid show, and the amateurs' show were all more or less successful, if only from the reason of attracting amateur exhibits, for it is greatly to be regretted that traders almost exclusively monopolize the space at the majority of the R.H.S. exhibitions, the fine exhibits by amateurs of pre-war years being greatly missed. The cause is not far to seek: the expense of exhibiting has increased greatly, and whereas traders can recompense themselves from the advertisement and trade they derive from exhibitions, amateurs nowadays find themselves unable to incur the great outlay. It was a wise move on the part of the Council of the Royal Horticultural Society to increase the money prizes for gardeners at the special fruit and vegetable exhibitions, but, even so, the balance to the exhibitor is on the wrong side even when he wins a fair share of the prizes, which should be made more liberal still. If something could be done to attract exhibits from the best of our private gardens to these metropolitan exhibitions it would, we think, be greatly in the interests of horticulture. The most gratifying feature of the past twelve months is the steady increase which all the special floricultural societies have made. The National Rose Society adds success to success, has a membership as large as the R.H.S. had at a time many of us can remember, and its shows have attained an importance in keeping with its membership. The National Chrysanthemum Society has also enjoyed a successful year; its autumn exhibitions have far outgrown the accommodation which the Horticultural Hall at Vincent Square affords. Remarkable progress has also been made by the National Dahlia Society, whilst the British Carnation Society, the National Sweet Pea Society and the Imperial Fruit show have all done good and useful work. The Orchid societies in the Manchester district finished the year in a stronger position than at the beginning and enter on the new year with the brightest prospects. In a review of the past twelve months the valuable work which has been done by the various horticultural and scientific institutions must not be overlooked, and although progress in this direction may seem slow, the cumulative results add greatly to our knowledge, both of the behaviour and requirements of plants and the conditions under which they succeed best. Gardens in 1925 were never more beautiful, for flowers were exceedingly plentiful, and seldom has their season been more prolonged, for the weather of autumn and early winter was kind, and only comparatively recently did the outdoor display finish. Some of the fruit crops were disappointing, but recompense was afforded in the bountiful yield of Apples, which have seldom been finer in quality. The vegetable crops have, with few exceptions, been remarkably good, and Potatos, which constitute one of our most important vegetables, yielded well above the average. With the decline of so many of the large gardens of the nobility, owing to the vastly increased cost in their upkeep, it is gratifying to notice the spread of municipal parks and gardens everywhere, indeed, in some cases large private gardens have been acquired for the purpose and converted into pleasuances for the citizens and town's folk. The beautifying of streets and boulevards with trees and shrubs in the town-planning schemes adopted by most of the important municipal authorities is another instance of horticulture adding to the amenities of our civic life, and the influence these public gardens and parks have in fostering interest in gardening amongst the community must be very great. The love of beautiful flowers and plants is reflected in the increased output by market growers, whose methods of culture, whilst necessarily specialised, are not excelled. Our gardens are still being enriched with new plants from other lands, thanks, largely, to the introductions by plant collectors in Asia, who have given us not only new flowering plants, but trees and shrubs of great beauty, and it is doubtless due to their discoveries and the introduction of new species of Rhododendron that this flowering shrub has become so fashionable and popular. When the new Rhododendron house at Kew is completed and planted, opportunity will be afforded of seeing these new Chinese and Tibetan species of Rhododendron growing and flowering. Apparently no great advance has been made with the proposed new horticultural hall and the Fellows of the R.H.S. will be anxious to learn from the report of the Council in February, when its erection is to be commenced. Most of the meetings of the special floricultural societies synchronise with the R.H.S. fortnightly shows, the Hall at Vincent Square being the "clearing house" of horticulture. If accommodation could be found for these lesser societies and organisations, including the trade associations, in the new building, we think that both horticulture and the R.H.S. would benefit thereby. The hand of death robbed horticulture of many of its distinguished exponents in 1925. Saddest of all was the untimely end of the capable Secretary of the Royal Horticultural Society, Mr. W. R. Dykes, who was also one of our most valued contributors. We have also lost by the death of Mr. William Watson, one of the finest plantsmen of contemporary times, and in Mr. James Whitton the prince of park superintendents. Amongst others whose loss we especially mourn are Mr. John Heal, whose special province was indoor plants which he grew so well and did much to improve; Mr. Elisha J. Hicks, the successful Rose grower; Mr. C. Harman Payne, a man of distinguished personality, and a great lover of florists' flowers; our colleague, Mr. J. K. Ramsbottom, a young man of brilliant promise; Mr. Horace J. Wright, a distinguished son of a distinguished father; Mr. Whitpaine Nutting, head of a famous seed firm; Mr. William Bates, a veteran gardener and one of the oldest Committeemen of the R.H.S.; and Field-Marshal Lord Grenfell, a former President of the Royal Horticultural Society.

The New Year.—The Editors and staff of *The Gardeners' Chronicle* tender their heartiest thanks to all contributors, correspondents and advertisers for assistance rendered generously during 1925, and to them and to a world-wide circle of readers they offer good wishes for 1926.

"The Gardeners' Chronicle" Almanac for 1926.—Our Almanac for the present year, giving the dates of the principal flower shows in Great Britain, and of the meetings of horticultural and botanical societies, is now being prepared, and will be published in our issue of January 9. Secretaries of horticultural, botanical and other societies are requested to send the dates of their shows, meetings, etc., not later than Monday, January 4, in order that they may be included in the Almanac.

Mushroom Maggots.—*Farmers' Bulletin* No. 789, issued by the United States Department of Agriculture, deals with Mushroom pests and how to control them. The troublesome maggots which infest Mushrooms are the larvae of two-winged gnats or flies belonging to several species. The female is capable of laying nearly a thousand eggs, and usually these are deposited at the junction of the stem and cap of the Mushroom, or in the manure or soil at its base. In a warm temperature, the eggs hatch within three days, and the larvae at once bore into the stem or cap of the Mushroom, riddling it and causing it to break down. Seven to ten days afterwards, the larvae enter the ground and pupate. The pupal stage lasts from four to seven days, when the adult insects emerge and soon commence egg laying. Amongst remedies recommended are the reducing of the temperature to 55°, fitting a gauze screen to prevent the gnats entering the house, and fumigating with carbon disulphide just previous to spawning. Fumigating with nicotine will kill the adult flies, and fumigation is recommended at least once a week while the beds are in bearing. Cyaniding may also be resorted to, and this should be done while the atmosphere of the house is relatively dry. The *Bulletin* also deals with the Mushroom mite, springtails, woodlice, slugs and crickets.

Public Grants in America for Agriculture and Horticulture.—The Department of Agriculture U.S.A., is providing for an increase of $2,600,000 in its estimates for the Budget Bureau. Of this sum, $80,000 (minus $1,000) is to be allocated for investigations of plant diseases and pathological collections ; $128,325 for investigations of diseases of orchard and other fruits ; $108,095 for the investigations of forest and ornamental trees and shrubs ; and $36,600 for the purchase. propagation, testing and distribution of new and rare seeds. The total appropriations of the Plant Industry Bureau are estimated at $3,748,325.

Late Planting of Trees and Shrubs.—The exceptionally severe weather during November and December has seriously delayed the contemplated planting of trees and shrubs throughout the country. In such circumstances gardeners are rather liable to overlook the nurseryman's side of the question, and forget how the untoward and totally unexpected early winter affects him. If only for a selfish reason, the nurseryman is always anxious to execute all orders for trees and shrubs as early in the autumn as possible. He is then able to take stock early in the coming year, and plant up the quarters in good time before the growing season arrives. It is small wonder, therefore, that very many nurserymen view the present conditions—and, we fear, letters urging the speedy delivery, which is impossible—with feelings akin to dismay. While the practice of autumn planting of hardy trees and shrubs, which has so many followers, has much to recommend it, we would point out that the work may be carried out for quite a considerable period with full confidence of success if ordinary precautions are taken. Although we have become accustomed to speak of autumn planting in connection with garden work, we need scarcely remind our readers that with our climate it is impossible to say when autumn ends and when spring begins. Every planter can recall seasons when, with but brief intervals, on account of rains or occasional light frosts, planting could have been continued from the fall of the leaf to the bursting of the new buds. Purchasers from reputable nurserymen may always have full confidence that the trees and shrubs have been properly prepared for transplanting, and, what is equally important, are well-packed, so that even though they are received a little later than would have been wished, no fears need be entertained, Indeed, if, as they say, the old saw—which has it that "when there is ice sufficiently thick to bear a man's weight before Christmas, there is not sufficient for a duck after"—holds good, this later receipt of nurseryman's stock will prove to be a blessing in disguise, and the later-planted trees and shrubs will be the more successful. As is well-known, planting of many species may be continued long after the first heralds of spring have arrived, provided the work is well and truly done, and the ordinary precaution of applying a light mulch over the roots, to prevent excessive evaporation. is practised.

Mr. Walter Charles Slocock, V.M.H.—While practically every nurseryman in the British Isles, and many over-seas, is well-acquainted with the business of "Slocock, of Woking," the name will probably be strange to most amateurs and private gardeners. This interesting anomaly in connection with our largest trade grower of trees and shrubs shows how distinct are the wholesale and the retail nurserymen in this country, for the enormous business of Mr. W. C. Slocock at Woking is wholesale. The vastness of the business may, perhaps, be realised when we mention that the Goldsworth Nursery has a road frontage of fully two miles, and there are various outlying nurseries. Mr. Walter C. Slocock was born at Wraysbury, but he comes from a family whose names are inscribed in the archives of Newbury so far back as A.D. 1600, where its members have long been engaged in the important businesses of banking and brewing. It will be seen that Mr. Slocock did not inherit his inclination to a nursery business. This may be said to have been the outcome of the long friendship between his father and Mr. Anthony Waterer, the noted nurseryman of Knaphill. and it was at Knaphill that Mr. Slocock commenced his career. He then spent four years in various other nurseries and also worked for a time in France, and in Belgium. Returning to England in the autumn of 1877, Mr. Slocock took over the old-established Goldsworth Nurseries, at Woking, which had then lost much of their former importance. It was originally owned by a Mr. Turner, and early in the eighteenth century Mr. Donald had made it famous for new and rare trees and shrubs. Loudon was a close friend of Donald and made frequent visits to the nursery. After the death of Mr. Donald, misfortunes seem to have fallen on the erstwhile famous Goldsworth Old Nursery, and, when Mr. Slocock took it over, its area had dwindled down to twenty-four acres. Mr. Slocock is modestly silent on the matter, but those who know him realise that by dint of strenuous and long days of hard work, combined with a keen intuition of values and demand, he has built up his present incomparable nursery business, which has a larger acreage and has produced a greater number of trees and shrubs than any other in this country, and probably in the world. In addition to his home trade, Mr. Slocock has exported enormously to the colonies, especially to Australia and New Zealand, and to the United States of America. His aim has always been in the direction of what may be termed mass production, which permits the profitable growing of the rarer kinds, which would otherwise be of prohibitive cost, and so creating a demand for them. Mr. Slocock possesses a strong personality, a generous disposition, and is blessed with a vigorous constitution and unbounded energy. The length of his working days would not meet with the approval of the trades unions, for he is in his office or the nursery early and late. Mr. Slocock has always declined public honours and responsibilities, and he finds sufficient relaxation from his absorbing business interests in his intense love for nature in every form. He has a wide knowledge of the difficult family of Coniferous trees and takes an especial interest in Rhododendron hybrids. In appreciation of the great work he has performed in the raising and distribution of the stocks of rare trees and shrubs, Mr. Slocock was awarded the Victoria Medal of Honour by the Council of the Royal Horticultural Society in 1916. Latterly, Mr. Slocock has received great assistance in the management of his enormous freehold nursery from his son, Mr. Walter Ashley Slocock, who, so soon as he became eighteen years of age, took part in the Great War, first with the Surrey Yeomanry and later as a lieutenant in the Royal Artillery. His second son, Mr. Oliver Slocock, is, as his father expresses it, "soon coming on," and he may have every confidence that, when the time comes, the traditions of Goldworth will be carried on and extended.

MR. WALTER CHARLES SLOCOCK, V.M.H.

Chilean Nitrate Industry.—According to the *Journal of the Royal Society of Arts*, the consumption of Chilean nitrate is gradually increasing ; the number of works in operation at the end of 1923 was eighty, compared with fifty-five out of a total of 150 in the beginning of that year. The production during 1923 was 1,903,524 metric tons, compared with 2,772,254 metric tons in 1913. Since the close of 1923 some ten or twelve additional works have resumed operations, and the rate of production is increasing correspondingly. During the past decade the United States has become the greatest customer of Chilean nitrate, and it is estimated that 900,000 tons were used in America in 1923. The world's consumption of nitrate is 2,170,000 metric tons. Germany, before the war, consumed about 800,000 tons per annum, or nearly as much as all the other continental countries combined.

Sweet Pea Lectures.—We feel sure that many horticultural and kindred societies will welcome the offer of the National Sweet Pea Society to provide expert lecturers on Sweet Pea cultivation. The principal members of the Society are prepared to give lectures on payment of their out-of-pocket expenses only. Secretaries of societies wishing to take advantage of this opportunity should write to the secretary of the National Sweet Pea Society, Mr. A. C. Bartlett, at 19, Bedford Chambers, Covent Garden, W.C.2, giving as long notice as possible, and he will arrange for a lecturer, who, whenever possible, will be selected from the neighbourhood in which the lecture is to be given. The N.S.P.S. is also willing to consider applications for special lecturers.

Transportation and Conservation of Ripe Fruits.—A lecture entitled "Some General Problems of the Transport by Sea and Conservation in Store of Ripe Fruit" will be delivered before the members of the Society of Arts, John Street, Adelphi, W.C., on Wednesday, January 27, at 8 p.m., by Dr. John McLean Thompson, F.R.S., Professor of Botany at the Liverpool University.

Admission Fee to Kew Gardens Reimposed.—The recommendation of the Select Committee on Estimates to reimpose the admission fee of one penny to Kew Gardens (see *Gard. Chron.*, vol. LXXVIII, p. 161) has been adopted by the Ministry of Agriculture and Fisheries, and took effect on January 1. The admission fee of one penny—on other than students' days—was abolished in April, 1924 : it previously yielded a revenue of about £5,000 per annum. The present admission fee of 6d. on students' days (Tuesdays and Fridays) will continue to be charged.

Bagatelle Rose Trials.—A trial of Roses will be conducted at Bagatelle as usual during the forthcoming season. Plants sent for trial should, if possible, be growing in pots, and at least five bushes of each variety should be dispatched, addressed "Roseraie de Bagatelle," Bois de Boulogne, Paris. The origin and type of Rose, together with any special cultural requirements, should be forwarded at the same time. The plants will be grown in the open for two years and will be judged in the October of 1927. The Superintendents of Parks, at the address given, will forward on application for same special labels, facilitating the admission of the plants without paying customs' duties.

An English Lady's Success in America.—The prize of $500 offered by the Garden Club of Allegheny, Pennsylvania, U.S.A., for the best painting of flowers or gardens in the twenty-fourth International Exhibition of Paintings at Carnegie Institute, Pittsburg, has been won by Miss Emily Court, a native of London, for her painting, "Blue and Silver."

Scotch Potato Registration Trials.–The Scottish Board of Agriculture has issued a summary of the report made by the Scottish Potato Synonym Committee relative to the registration and immunity trials held at the Board's Plant Registration Station. In the first year's test the varieties numbered one-hundred-and-four and of these the committee found that ten were identical with immune standard varieties, fifty were distinct and free from Wart Disease, seven resembled, but were inferior to, immune standard varieties, twenty-one were identical with non-immune standard varieties, thirteen were susceptible to Wart Disease, and three stocks were too mixed or diseased for consideration. The varieties in respect of which the final decision as to type was deferred until after the second test in 1925 numbered eighty-three, and the results were as follow :—discarded by growers, fifty ; identical with immune standard varieties, nine ; distinct from any known type and immune from Wart Disease twenty-two ; seedlings resembling, but inferior to, immune standard varieties, two. Five varieties were grown in 1925 with a view to registration, but only one, Arran Consul, raised by Mr. Donald McKilvie, Lamlash, was successful. It is reported to be a very satisfactory cropper, and to possess a marked capacity for resistance to blight, and the standing committee of management has endorsed the recommendation. The following is the official description of Arran Consul :—Tuber, round to oblong ; skin white, flesh white ; eyes shallow, sometimes deep in large tubers ; sprouts, pink ; haulm, tall, upright, very open ; stems, branching ; wings, broad ; leaf, markedly open ; leaflets, medium green, dull, narrow ; stalks, long ; secondary leaflets very inconspicuous ; flowers, white, infrequent ; maturity, early maincrop.

Dr. G. Claridge Druce.—At the celebration of its jubilee, held recently, the Société Botanique de Genève appointed Dr. Claridge Druce a corresponding member. Dr. Druce has also been chosen as correspondent by the Council of the National Museum of Wales. He has prepared the Botany of Huntingdonshire for the "Victoria County History of Huntingdonshire," and also dealt with the botany of Berkshire, Buckingham, Oxford and Northampton, for the "History" of these counties.

Appointments for the Ensuing Week.—Sunday, January 3 : Wakefield and North of England Tulip Society's meeting. Monday, January 4 : Romsey and District Gardeners' Association's meeting. Tuesday, January 5 : Royal Caledonian Horticultural Society's meeting. Wednesday, January 6 : Abingdon Horticultural Society's meeting. Thursday, January 7 : Manchester and North of England Orchid Society's meeting. Friday, January 8 : Royal Horticultural Society of Ireland Council meets ; Accrington and District Chrysanthemum Society's meeting.

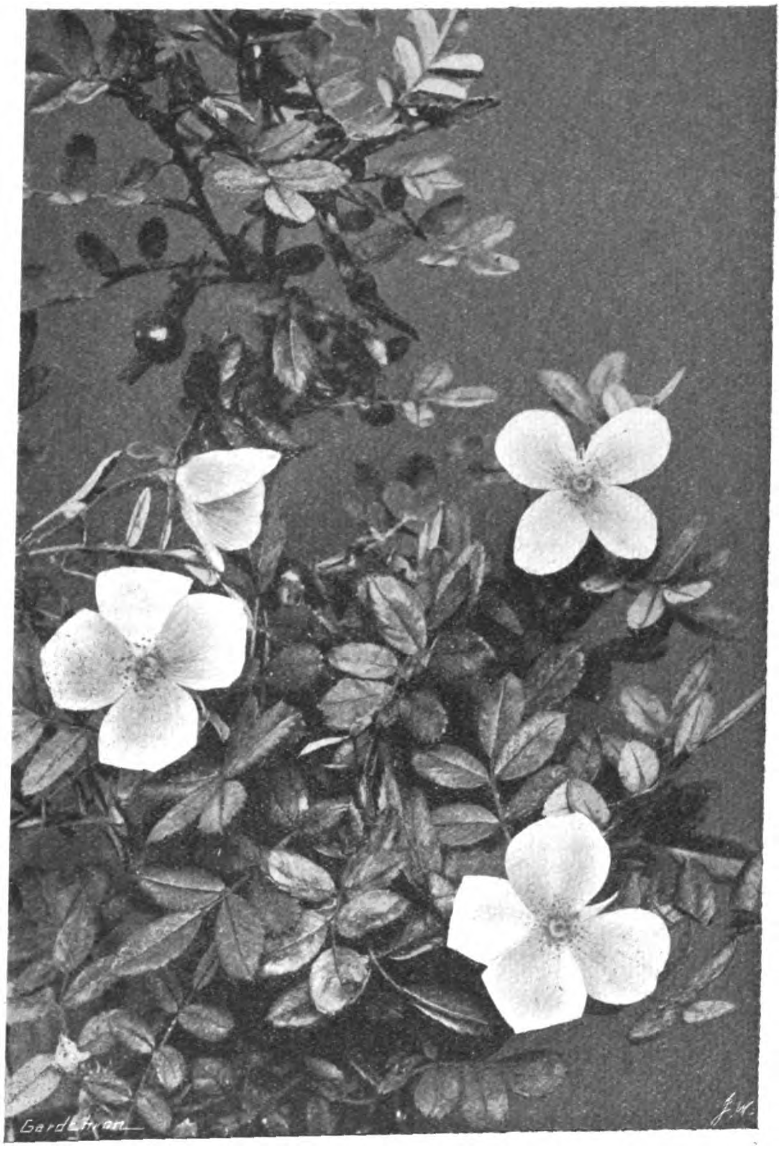

FIG. 1.—ROSA SERICEA.

(see p. 7).

"Gardeners' Chronicle" Seventy-five Years Ago.—*Chinese Azaleas and Azalea Gardens.*—Little more than an hour's walk brought me to the garden I had come to visit. There were no external marks, such as name or signboard, to direct the stranger to the garden ; indeed, a person unacquainted with the customs of the Chinese would never have dreamed of finding such a beautiful place as this is, in a poor country village. Going up a narrow passage between two houses I reached the residence of the nurseryman. He received me with great politeness, asked me to sit down in his house, and called to one of his sons to bring me a cup of tea. Having sipped the favourite beverage, I then walked out with him to inspect his garden. In the front of the house where we had been sitting, three or four flat stages were covered with Japanese plants, of which the old man had a good collection. A small species of Pinus was much prized, and when dwarfed in the manner of the Chinese, fetched a very high price ; it is generally grafted on a variety of the Stone Pine. The Azalea obtusa, and some varieties of it with semi-double flowers, were in full flower, and highly prized by the Chinese. The colour of this species is much more brilliant and dazzling in China than I have ever seen it in England. A beautiful variety, quite new, had small, semi-double pink flowers, which it produced in great profusion. This will be a great favourite in England when introduced to our gardens. Its novel colour, small leaves, and neat habit will render it most desirable for bouquets and other decorative purposes. I have named it Azalea amoena. On the stage with this plant I observed a new species of Holly, which is likely to be of some value to English gardens. I have named this species Ilex Reevesiana, and thus describe it :—a dwarf shrub ; leaves entire, elliptical, acute, slightly wavy ; dull green, and covered over with small dots, somewhat like Elaeagnus ; flowers on short spikes, terminal : fruit large, of a deep red colour. A very ornamental bush, which flowers in the winter months, and ripens its fruit during the following autumn like our common English Holly. It is the Wang-sang-qui-wha of the Chinese, and said to have been brought from Wang-San, a celebrated mountain in Hwny-chow. *Robert Fortune, Gard. Chron., January* 4, 1851.

The Week's Work.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Seasonable Remarks.—If the general cleansing of the houses and their occupants has not already been done it should be completed as quickly as possible. The wood-work and glass, both inside and out, should be thoroughly washed. The plants should be examined for the presence of insect pests. The leaves and pseudo-bulbs of a number of Orchids are fully matured, and cleansing operations may be carried out with little risk of injury to the plants. One of the worst insect pests of Orchids is a soft white scale that conceals itself under the outer sheath of the pseudo-bulb and on the rhizomes. The members of the Cattleya family are particularly subject to injury by this insect. Their destruction and removal may be accomplished by the aid of a suitable insecticide. When a number of plants require cleansing, place sufficient insecticide, mixed with tepid water to the desired strength, in a utensil sufficiently large to permit of the plant being immersed head downwards in the specific, well wetting the leaves and pseudo-bulbs. After withdrawing the plant hold it over the receptacle for a few moments to drain, then place it on its side for a short time, after which the plant should be examined and sprayed. If the insects cannot be removed with the sponge, a pointed stick or a stiff brush may be employed for the purpose, always taking care not to damage the buds. The grower who keeps his stock clean starts with a great advantage over those whose plants are infested with pests and diseases, and therefore every effort should be made to eradicate pests of all kinds directly they are detected.

Temperatures.—Orchids, as a general rule, are very sensitive to fluctuations in the temperature, and they cannot long continue in good health unless suitable surroundings are maintained. The weather at this period of the year is apt to change quickly, which often makes it difficult to maintain the desired temperatures in the various divisions. The following readings should be maintained as nearly as circumstances will permit. Odontoglossum or cool house, 50° to 52° at night, 55° during the middle of the day, but with sun-heat it may be allowed to rise to 60°; Cattleya house, 60° at night to 65° by day, or a few degrees higher with sun-heat; East Indian or warm house, 65° at night and 75° during the middle of the day. A moist atmosphere should be created by damping the floors and stages at least once daily, but in this respect the grower should be guided by the amount of fire-heat employed to maintain the requisite degree of warmth. The temperatures I have given should be in accordance, more or less, with the weather. When it is extremely cold a degree or two below the figures given will cause less harm to the plants than the use of excessive fire-heat, while the use of the lath blinds or some other covering material at night will greatly economise the warmth during frosty or windy weather, but the protection on the roof should always be removed as early as possible in the following morning.

FRUITS UNDER GLASS.

By T. PATEMAN, Gardener to SIR CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Cucumbers.—In order to ensure a constant supply of Cucumbers during the next two months great care and attention are necessary in watering and feeding the plants. To be successful at this season of the year the plants should be trained thinly and cropped lightly, for if they receive a check through over cropping successional fruits will not be forthcoming. Top-dress the roots on frequent occasions with a light, rich compost warmed to the temperature of the house, and maintain a night temperature of 65°. Promote a moderately moist atmosphere by damping the beds and paths, but the grower should be guided in this matter by the condition of the weather. Sow seeds to obtain plants for a succession.

Melons.—If it is desired to have ripe Melons in May the present is a suitable time to sow seeds to obtain the necessary plants. With the turn of the year the seeds of Melons will be found to germinate more readily than those sown during December, and moreover, the plants will grow more freely and sturdier than those raised at an earlier date. It is not advisable to attempt to grow early Melons unless the grower has plenty of heat at his command, for once the young plants receive a check caused by a low temperature during the early months of the year, they invariably finish their crop unsatisfactorily. The seeds should be sown in small receptacles filled with a light compost, and the soil should not be pressed too firmly. Place two or three seeds near the sides of the pot or pan and cover them lightly with soil. Plunge the pots in a brisk bottom-heat and cover them with a sheet of glass. If the compost is in a moist condition watering will not be necessary until germination takes place, when the seedlings should be placed on a shelf near the roof-glass in a house having a minimum temperature of 65°.

THE KITCHEN GARDEN.

By F. STREETER, Gardener to MAJOR ALBERT PAM, Wormley Bury, Broxbourne.

Introductory Remarks.—The superior cultivation of vegetables and salads should be regarded as of the utmost importance in all gardens. To procure the required daily supplies calls for much forethought on the part of the gardener. Deep cultivation is absolutely essential so that the first attention should be given to bringing the whole of the kitchen garden into first-class condition by trenching the ground, adding plenty of good farmyard manure, leaf-mould, burnt earth, road scrapings free from oil, etc. Where the existing soil is deficient in lime, a good dressing of this material should be applied. See that plenty of finely-sifted soil, burnt earth, wood ash, etc., is prepared and stored in a dry shed ready for the fast approaching seed-sowing season. Have also plenty of sound boxes and pots of various sizes ready for use. The pots should be washed, or if new, soaked thoroughly before using them. Clean crocks broken into suitable sizes, and labels of various sizes should be held in readiness for use. All tools should be put in good condition, so that there will be no delay when the busy season arrives.

Seeds.—The seed catalogues are to hand, and should be carefully studied. Mark off the required items that are known to suit the particular district and order a few novelties. Post the order so soon as possible, and when the seeds are received, check them off and place them in their correct order for sowing. See that they are kept cool and perfectly dry. It is not advisable to trust to old seeds, as this may lead to a serious break in supplies. Keep a sharp watch for mice which may do great damage in the seed stores.

PLANTS UNDER GLASS.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

A Retrospect.—With the beginning of the New Year it is well to pass in review successes and failures of the past year. Failure with any particular plant or class of plants is usually due to circumstances which the grower can more or less control. To take the subject of propagation, for example, success with many plants depends very largely on their being propagated at the proper time, especially when it is required to have certain plants in flower at a particular date. The grower should also consider carefully what plants are best suited to the requirements of the individual establishment, and here the taste of the employer must be considered.

Seed Lists.—There should be no delay in going through the seed lists and placing the orders in good time, for the seedsmen deal with their orders in rotation. When ordering seeds or plants it is a good plan to try a few new subjects each year: it is interesting to grow new plants, and there is always the chance that one or more will prove acquisitions. Numbers of plants that should be more generally cultivated are easily raised from seeds. Tuberous-rooted Begonias are usually raised from seeds but the fibrous-rooted section, as represented by the many fine varieties of Begonia semperflorens, are very much neglected for conservatory and greenhouse decoration. They are largely used for summer bedding schemes in the south, but in the north and colder parts of the country they should be more generally grown for conservatory decoration. Plants raised from seeds sown during January will provide a display, during the summer, while a March sowing will furnish plants for flowering in autumn and winter.

Annuals.—Annuals play an important part in conservatory and greenhouse decoration, and are usually sown during September, but where this has been neglected, good results may be obtained by sowing during the present month; indeed, in the immediate neighbourhood of London, better results are obtained by deferring the sowing until the beginning of the year, as fogs and lack of sunshine make it very difficult to carry young seedlings of this type safely through the winter. Clarkia, Mignonette, Schizanthus, Rhodanthe, Acroclinium, Alonsoa, Collinsia bicolor and Nemesia, in fact, all the kinds usually grown for this purpose may be sown during January. Plants raised from seeds sown last September and wintered in small pots should now be ready for transference to larger pots, which will vary in size according to the subjects and the purpose for which they are required.

House Cleansing.—Cleanliness in plant houses is of prime importance, and it is wise to get as much house-washing done as possible before the season is too far advanced. The glass and wall surfaces should be scrubbed and the walls lime-washed, adding a litle cement to the wash to make it adhere better; a forty-eight-sized potful of flowers of sulphur should also be added to each bucketful. Propagating cases should be also overhauled and cleansed, substituting old plunging material with new where required.

THE FLOWER GARDEN.

By F. C. Puddle, Gardener to Lord Aberconway, Bodnant, Taly-Cafn, North Wales.

Trees and Shrubs.—Owing to the severe weather experienced during the past two months, the majority of gardeners will commence the year with planting operations much in arrears. Where beds have been trenched in preparation for planting, nothing can be done until the ground is in a fit condition, but where it is intended to plant in grass or woodland, the work may be proceeded with in fine weather. It is not advisable to dig the holes before the day of planting, and dry soil should be used around the roots, but if dry soil is not available, a mixture of leaf-mould and sand will be helpful. When small shrubs of doubtful hardiness are received from the nurseries it is advisable to pot them and place them in frames until April, when they may be planted out with greater safety.

Viburnum fragrans.—This winter-flowering, Chinese shrub of comparatively recent introduction has amply proved its hardiness, and is worthy of extensive planting. At Bodnant it usually commences to flower towards the end of October and continues until February. It has been flowering freely during the recent severe weather, and with the exception of a slight browning of the fully-expanded flowers when 15° of frost was registered, it appears unaffected by any climatic conditions, no matter how bad. That a deciduous shrub should flower continuously for over three months, and that at mid-winter, seems almost an impossibility, but in the case of Viburnum fragrans it is a reality. The sweet-scented flowers are white, slightly tinged with pink; they are borne in clusters on short, twiggy branches, and at the extreme end of the current season's growth. It is a good, upright growing shrub having none of the weaknesses of V. Carlesii, and may be easily propagated by cuttings, which should be inserted about July. Hamamelis mollis, another Chinese introduction will have opened its flowers ere these notes are in print. A mixed planting of this and Viburnum fragrans, with a dark background, such as would be obtained by Hollies or Yews, would provide a winter scene of great beauty, the delightful fragrance of the flowers being an additional attraction. If an edging or groundwork is needed for the group, this may be furnished by planting either Erica carnea or E. darleyensis.

HARDY FRUIT GARDEN.

By W. Auton, Gardener to Viscount Elveden, Pyrford Court, Woking, Surrey.

Peaches and Nectarines.—There are few more profitable fruits for growing on a warm south wall than Peaches and Nectarines, and although the possibilities of growing these delicacies as bush trees is not generally realised, most gardens of any pretentions have their Peach wall. As a matter of routine work the growths will probably have been cut from the wires and tied in loose bundles. This facilitates a thorough cleansing of the wall, and also helps to keep the buds dormant, as if the growths are close to the wall periods of bright weather have the effect of inciting the fruit buds to swell prematurely under the exceptionally favourable conditions which the wall provides. If the cleansing of the trees has not already been done, this should now be undertaken and the branches thoroughly cleansed before again tying them into position. The summer disbudding of Peach trees constitutes in effect their pruning, and if the old wood was removed immediately after the gathering of the crop little remains to be done in this direction now, but crowding should be guarded against rigidly, and any shoot which has not ample room for development removed entirely. In a general way, no shortening of the shoots is necessary, but where this is practised to preserve the balance of the tree shorten to triple buds. When the overhead work is completed as much of the surface soil should be removed as is practicable, and good turfy loam mixed with plenty of lime rubble and a little bone-meal substituted. The surface may then be mulched with decayed manure.

Vines.—It is preferable to prune Grape vines in the open so soon as the leaf falls, and if not already completed the work should be done forthwith. If the pruning of vines is too long deferred bleeding is bound to be profuse when the sap rises, and consequently a waste of vital force results. If pruning is done on the spur system, one bud or at most two is sufficient to leave at the base of each shoot, and if wood for extension is needed the young growths should be carefully trained in at about eighteen inches apart.

Bush Fruits.—Whereas Red Currants and White Currants produce their fruits from spurs developed on the wood of earlier years, Black Currants fruit on the previous year's growths, hence the methods of pruning differ fundamentally. There is no better system of pruning Black Currants than that of removing all the old wood not wanted, immediately after the crop is cleared, and although this is frequently impracticable in field culture because of the labour involved, it is usually possible in private gardens. A bush of Red Currant or of White Currant should consist of a number of main stems radiating from the base, on which all side shoots should be cut back to cause fruiting spurs to develop on the whole of their length. This also is better effected by summer pruning, which leaves little to be removed in the winter. Gooseberries fruit on the previous year's growth as well as from spurs on older wood, and their pruning consists largely in thinning the branches so that the picking of the fruit can be done comfortably. In districts where birds are very destructive it is wise to defer pruning until the buds are beginning to burst.

Preparations for Planting.—Whilst arrears of planting cannot advisably be undertaken until another month or so, it is well to make full preparations for doing this work. So soon as the soil becomes reasonably dry and workable ground intended for the planting of fruit trees should be trenched or dug, according to circumstances. Where the subsoil is of a cold, retentive nature, deep digging is to be preferred for fruit trees to trenching, for it is not desirable that the roots should grow into an unkindly medium; rather should they be encouraged to develop near to the surface where they will be warmer and receive plenty of air. Where fruit borders are known to be insufficiently drained, this defect should be remedied, even if the border has to be renewed.

FOR NORTHERN GARDENERS.

By A. T. Harrison, Gardener to the Marquis of Ailsa, Culzean Castle, Maybole, Ayrshire.

Arrears of Work.—With the advent of the New Year, all arrears of work from whatever cause should now be resolutely completed. All vacant ground in the kitchen garden should be worked deeply and the surface left in a rough condition to benefit by exposure to the weather. The pruning of bush and standard fruit trees should be done during mild weather, and when inclement weather prevails advantage should be taken of it to wash and cleanse both plant and fruit houses.

Preparations for Seed Sowing.—It is a good plan to have a quantity of soil brought under cover in good time in order that it may be available when required; sufficient quantities of leaf-mould and sand should also be at hand, while seed-boxes, pots and pans should all be looked over and washed, if necessary. If large Onions, either for home use or exhibition are required, the present is a suitable time to sow the seeds in boxes, covering them at least a quarter-of-an-inch deep with finely sifted soil. Germinate the seeds in a house with a night temperature of 50° to 55°.

Propagating.—This is also an ideal time for propagating stocks of Chrysanthemums, perpetual Carnations, etc. Although the bulk of cuttings of the former plants are inserted in November and December, there are always some varieties that are shy in forming shoots suitable for use for cuttings, and these should be dealt with as they become available. In the case of perpetual Carnations, while these may be propagated from October till March; cuttings inserted the first week of the year and grown steadily on always make good plants, and are ready for cooler quarters before the space in the propagating house is required for other subjects.

Hot-beds.—The present is a suitable time to collect the dung and leaves for making hot-beds, and turn them over once or twice to become thoroughly mixed. The beds should be made at least three feet wider than the portable frames used for them, and from three to four feet in height. Crops of early vegetables may be economically forwarded by these means, and the heap comes in useful for growing Vegetable Marrows during the summer, and later forms a part solution of the question of animal manures for the kitchen garden, as by the time digging begins next autumn and winter, the leaves and dung are in a suitably decomposed condition to be used for this purpose.

INDOOR PLANTS.

NAEGELIA.

THIS beautiful genus is included in the Natural Order Gesneraceæ, and comprises some six species, most of which have at some time or another been included among the Gesneras. They are natives of Mexico and Central America, and are generally regarded as stove plants, although they succeed quite well in an intermediate temperature, and, when in flower, in a warm greenhouse.

N. cinnabarina (syn. Gesnera cinnabarina, *Bot. Mag.*, t. 5,036) is a beautiful winter-flowering species, the flowers scarlet with a light throat, while the cordate, green leaves are beautifully shaded with flame-coloured hairs. Naegelia zebrina (syn. Gesnera zebrina, *Bot. Mag.*, t. 3,940) flowers throughout the autumn and winter, and has bright, orange-scarlet flowers, with bars of deeper colour down the side of the tube. A batch of this species has been in flower for over two months in the conservatory at Kew, thus proving its value for autumn and winter flowering, especially considering the adverse atmospheric conditions that obtain here during the winter season, when one night's fog often ruins the work of the previous six or nine months.

N. multiflora (syn. N. amabilis, *Bot Mag.*, t. 5083) has white or creamy-white flowers, and has no doubt played an important part in the production of the present-day garden race of Naegelias. I doubt whether this species is in cultivation to-day, and the same may be said of N. fulgida and N. Geroltiana (syn. Gesnera Geroltiana).

At the present day, the genus is generally represented in gardens by hybrid varieties (see Supplementary Plate), or, perhaps more correctly, by garden forms raised from seeds. At one time there were many named varieties, but at the present day, with the exception of the fine variety known as Orange King (finely shown by Mr. Howard Palmer, Northland, Wokingham, at the R.H.S. Hall, on October 20, 1925), there seems to be few named varieties offered for sale. This is not a serious matter as Naegelias are easily raised from seeds, and a batch of seedlings usually gives many fine colour variations, ranging from white and yellow through shades of orange to orange-scarlet. Rosy-red suffused with pink is the colour of the beautiful hybrid Walmsgate Beauty, raised at Oxford Botanic Gardens; not the least charm of this plant is its beautiful leaves, which are thickly covered with dark crimson hairs.

Any named variety, or selected seedling, is easily propagated by means of the scaly rhizomes, or by stem and leaf cuttings, the last affording a quick and ready means of increase.

Seeds may be sown during January, in pots or pans, in a light sandy compost, which is best watered a few hours previous to sowing the seeds. The latter are very small and should be carefully distributed over the surface of the soil in the seed-pan, and covered with just a sprinkling of silver sand. The pan should then be covered with a piece of glass and kept shaded until germination takes place. In a temperature of 60°, germination soon occurs, and the seed-pan should then be stood well up to the roof-glass. When fit to handle, prick the seedlings into well-drained pans filled with light, sandy compost, and when large enough, the young plants may be potted off singly into small pots, or three plants may be placed in a larger pot, afterwards potting them on as they require it. Naegelias are best flowered in five- or six-inch pots. Plants raised from seeds sown during January should flower towards the end of summer or in the autumn. During the growing season a temperature of 60° is sufficient, with plenty of atmospheric moisture.

The potting compost should consist of good fibrous loam, with the addition of some lumpy peat and enough sand to render the whole open and porous; the pots should be well-drained and the compost made only moderately firm.

When the plants have completed their growth they should be rested, by drying them off for a time; afterwards the scaly rhizomes may be started into growth according to requirements, the earlier batches to flower during the autumn, while those started later will give a good display during the winter.

Naegelias are very subject to attacks of mealy bug, which must be guarded against, for once the pest is established on the hairy leaves it is very difficult to eradicate. In common with most plants of this class, Naegelias are subject to attacks of the Begonia mite, which, however, may be prevented by the use of the sulphur vaporiser. *J. Coutts, Kew.*

ORCHID NOTES AND GLEANINGS.

LAELIA ANTOCEPS.

THE first inflorescence of this interesting new hybrid between Laelia anceps Ballantineana and L. autumnalis is sent by the raisers, Messrs. Sanders, St. Albans.

It is a valuable addition to winter-flowering Orchids, and intermediate between the parents, though in form and tint it more nearly approaches a large L. autumnalis. The tall, two-flowered spike has flowers with white sepals and petals tinged with pale mauve, the base of the lip being similarly coloured, and the showy ovate-oblong front lobe is bright rose-purple, the basal part around the keeled crest being white. Some purple lines, as in L. anceps, appear on the inside of the base of the lip.

It is interesting to compare this hybrid with L. Finckeniana (albida × anceps), a natural hybrid certificated in 1892, as the differences in the present hybrid proves the correctness of the suggested parentage of L. Finckeniana, which was illustrated in *Gard. Chron.*, December 30, 1893, p. 805.

MAXILLARIA VENUSTA.

A FLOWER of this elegant and profuse flowering species, which is making a fine show in his collection, famous for the number of rare old species, is sent by J. McCartney, Esq., Hey House, Bolton.

The species was first introduced and flowered in 1851, and in the days when collections of specimen Orchids were a leading feature in exhibitions, it was one of the most effective exhibits, the late Mr. J. Cypher often showing specimens of it with sixty to eighty flowers, the acuminate sepals extending six inches.

The delicately fragrant flowers are white, the small lip in the centre being yellow with some red markings. The blooms are arranged round the plant on curved stems, ten or twelve inches in length. This Maxillaria is one of the most graceful and attractive species of the genus; it is illustrated in the *Bot. Mag.* t. 5296.

MORMODES COLOSSUS.

J. MCCARTNEY, ESQ., Hey House, Bolton, sends a strong spike of the rare Mormodes colossus, the upper half of which bears eight distantly arranged flowers, the lanceolate sepals of which extend over four inches. The sepals and petals are recurved at the margins; they are yellow, tinged with rose at the base, and have parallel lines of reddish purple from the base to the tip. The ovate-cordate lip is incurved and rolled back on the extreme half, the edges meeting at the back. The colour is bright light yellow with some small purplish spottings on the outside, and dotted lines of the same colour in the interior.

This Orchid was introduced by Warscewicz from Central America, in 1850. M. colossus is of the M. buccinator section, a species which is the most variable in the genus, but which always bears the flowers in a dense head, while the larger species of the colossus section have them loosely displayed. M. colossus is illustrated in *Bot. Mag.* t. 5840.

TREES AND SHRUBS.

AUCUBA JAPONICA MACULATA.

I FULLY expected my note (Vol. LXXVIII, p. 429) on this species to stimulate some discussion. I am pleased that it has done so. There must be a certain amount of confusion in the matter. Mr. Comber states (p. 472), that "the spotted-leaved type is female, and has been recognised as such for forty years." I wonder if the recognition has been universal. I have before me a catalogue, issued in 1909-10 by Messrs. Clibrans, in which the following occurs:—"Aucuba japonica maculata. The variegated male Aucuba, 1/-, 1/6, 2/6 and 3/6 each." "Aucuba japonica maculata; the female form of maculata, 9d., 1/-, 1/6 to 3/6." Nothing is said about the latter being variegated, and the prices lead one to believe that it in any case is not so much variegated as the former. This is in accord with my own observations.

Whenever I have examined the flowers of a variegated Spotted Laurel they have been found to be staminate. Whenever I have examined the flowers of the green form they have been pistillate. I agree with Mr. Comber that my observations may have been faulty and my teacher may have taught false doctrine. To err is human. My botanical teacher, at whose feet I sat for nine years, and whom I shall honour to my journey's end, was the late William West, F.L.S., of Bradford. Of him it was said, at a British Association meeting, that in some branches of biological knowledge he had no superior in Europe. In looking up my class notes I find it distinctly stated that the Spotted Laurel is dioecious. I, like Mr. Comber, have seen berries on both forms of the Spotted Laurel, which makes me wonder whether the species has ever been entirely dioecious, or whether it has been dioecious at one time and is not so now. I am interested in Mr. Comber's remark concerning bees. He seems to imply that they may pollinate the flowers. Personally, I have rarely seen a bee on the flower of a Spotted Laurel. Flies visit the flowers in great numbers, and they may play some part in cross fertilization. *Geo. H. Copley, N.D.H.*

ROMNEYA COULTERI.

I WAS surprised to see, on p. 428, your contributor, A. T. Johnson, referring to the propagation of Romneya Coulteri by means of suckers, because, not so very long ago, Mr. Correvon, writing in *The Gardeners' Chronicle*, stated that the most apparent difference between R. Coulteri and R. trichocalyx was the fact that the former never produced suckers, while the latter was most profuse in this respect, and threw out quantities of them, sometimes long distances away from the parent plant.

This statement agrees with my experience of R. Coulteri here, where it has been established and has grown and flowered well for over twenty years, and never once have I found any suckers straggling away from the old stools, and we have always raised young plants by means of root-cuttings.

I have no plants, to my knowledge, of R. trichocalyx to prove Mr. Correvon's statement, but, rightly or wrongly, I regard him as a good authority. I should like to know whether other growers of this Californian Poppy have found suckers on their plants, and, if so, can they definitely say which species they are growing, as I believe R. trichocalyx, being the more easily propagated, is frequently supplied instead of R. Coulteri. *A. T. Harrison.*

GARRYA ELLIPTICA.

VERY fine effects are again being produced by this winter-flowering shrub, its innumerable grey-green catkins hanging in clusters. Where this evergreen does well it is most attractive in December. It withstands the sea-breezes well, and several plants growing on the top of the cliffs, sheltered only by a low wall, have now overtopped the wall, and are forming round-headed bushes from six to ten feet tall each one covered with a full crop of its interesting, if not particularly showy, catkins. These catkins have been copied, I am told, by those artists of a past generation who were responsible for the interior decorations in many of the mansions in this country, and, although not familiar with this aspect of the subject, I believe that fairly exact reproductions may be found in many of those mansions accredited to the brothers Adam, or belonging to that period.

The hybrid, G. Thuretii, although interesting as a vigorous-growing evergreen, does not flower until June, and is not to be compared with G. elliptica, the catkins being very much smaller and somewhat inconspicuous. *A. T. Harrison.*

ROSE GARDEN.

ROSA SERICEA.

THE silky-leaved Rose—Rosa sericea—was first discovered by Wallich at Gossan Than, in the Himalayas, but it is a species distributed widely throughout northern India, Upper Burma and Central China. It is variable, indeed, some authorities consider that certain forms belonging to the sericea group deserve specific rank.

Rose sericea (Fig. 1, p. 3), forms a spreading bush, so much as ten feet or twelve feet tall; it has arching growths, abundant foliage, and creamy-white, four-petalled flowers, which may be one-and-a-half inch to two inches across. The flowers are followed by red, somewhat Pear-shaped fruits. R. sericea is also interesting as being one of the earliest of Roses to bloom. The species was illustrated in *The Botanical Magazine* (t. 5,200), in 1860, where the information is given that it was "introduced by Dr. Hooker and Mr. Strachey into our gardens, where it proves hardy, and is best treated by nailing against a wall. Thus situated, its blooms are abundant in earlier summer."

Although the species is not extensively cultivated for garden decoration, the variety pteracantha has found considerable favour by reason of the attractiveness of the stems, which, when young, are covered with vivid red, translucent spines. These spines may be so much as one-and-a-half inch wide at the base, thin, and sharply pointed—effective alike in colour and armature. In this variety however, the flowers are smaller than in the type. R. sericea var. pteracantha was first raised at Les Barres, in France; it is a native of Western China, but a very similar form has been found in Manipur.

NOTES FROM WISLEY.

AT this time of year few plants have yet begun to flower in the alpine house. This does not mean, however, that such a house lacks interest. On the contrary, many alpine subjects are as fascinating in habit and foliage at the present season as they are when in bloom.

Among the many attractive plants with rosettes of leaves growing in the alpine house, those of Saxifraga Griesbachii and of the narrow-leaved S. Biasolettii are particularly handsome. The under-surface of the leaves of some forms of the first-named plant are tinged with purple, a feature which is still more pronounced in the case of other plants, such as Oxalis violacea and Lewisia Cotyledon. It occurs also in the mauve-flowered Wulfenia Amherstiana, which has just finished blooming on the rock garden.

Another plant with beautiful foliage to be found in the alpine house is a species of Potentilla, which is covered with long, silken hairs. These are most abundant on the underside of the leaves and on the stems. Fine, silvery-grey carpets are formed by Saxifraga Rocheliana and Raoulia australis, which looks particularly attractive when the sun is on it, while the crinkled leaves of Ajuga reptans metallica crispa have a steely-blue sheen. This is even more obvious in plants grown in the open.

In the field garden, most of the deciduous trees and shrubs have by now lost their foliage, with a few exceptions, such as Quercus coccinea, which still retains many of its red leaves, but much of the colour to be seen a month or so ago has gone. Around the large pond, however, many plants with brightly coloured stems are now conspicuous. Foremost among these is a specimen of Salix alba pendula aurea, the long, arching shoots of which are bright yellow. A red-stemmed Willow is to be seen in Salix coccinea, while a silvery sheen covers the stems of Salix pruinosa. The latter is still more attractive when the flower buds start to expand.

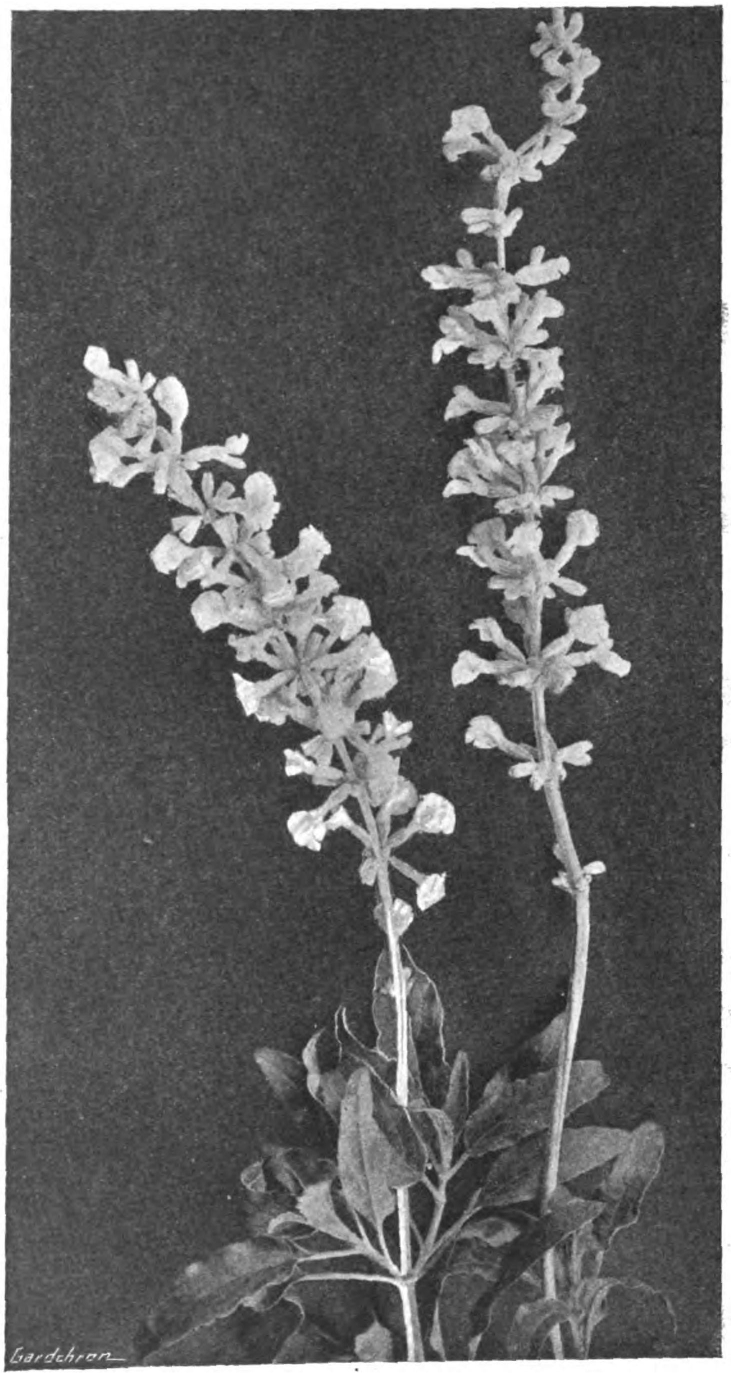

FIG. 2.—SALVIA FARINACEA.

In addition to Willows, plantations of Cornus, such as C. sanguinea and the darker-stemmed C. atrosanguinea, make bright splashes of colour, and the young shoots of Berberis yunnanensis which have nearly shed their leaves, now show up a brilliant red. Mention must also be made of a group of Sea Buckthorn, Hippophaë rhamnoides, whose silver stems are no less effective.

Marked improvement is already noticeable as a result of alterations which are being carried out in this part of the gardens. The old, Ivy-covered Oak tree at the entrance to the field garden has been removed, and a collection of flowering Cherry trees planted. A start has also been made on the work of developing the ground which adjoins the river. Hitherto, very little has been done in connection with this part of the gardens, which probably offers more scope for the production of fine garden pictures than any other portion.

Among plants under glass, the Carnation trial affords a continuous display of bloom, while Lachenalia pendula superba is flowering among other plants of this genus which are on trial. Several varieties of Nerine also are in bloom, including Nerine Bowdenii gigantea, N. flexuosa alba, and the vivid pink N. Mansellii.

In one of the propagating pits, the mealy-stemmed Salvia farinacea (Fig. 2), has been flowering well in company with Asclepias curassavica, which bears yellow and orange flowers.

Entomological investigations which are carried out by Mr. G. Fox-Wilson, have resulted in the discovery of a species of mealy bug which attacks the roots of Dianthus plumarius. It has now been named Ripersia dianthi. *J. E. G. White.*

NOTES FROM EDINBURGH.

DURING part of November and December Edinburgh experienced a great deal of frost and some fog, the effects of both have been felt by plant life. The premature ending of the display of Columnea gloriosa superba, and of certain Orchids, especially Laelias, is ascribed to fog. The effects of frost have been felt by Rhododendrons and some other evergreens but it is not yet possible to say how much real damage has been done.

Nothing of great interest is flowering out-of-doors, and one must look to the greenhouses for any effective colour. One of the brightest displays is made by Monochaetum alpestre, a shrubby plant which is trained up a wall in the corridor. It is a member of the Melastomacea, a family which contains several valuable genera of garden plants. The flowers are pink, and when the plant is trained in the manner mentioned, a very fine display may be made. Acacias become very valuable at this season of the year, either when grown in beds or in pots. Particularly noticeable just now are Acacia acinacea, a handsome plant, of graceful habit, producing a quantity of fine yellow flowers, and A. linearis, which, although not so showy as the former, has a graceful habit. Its flowers are pale yellow and much smaller than those of A. acinacea. A richer tint is assumed by the flowers of A. rostellifera, which is valuable also for its greyish-coloured phyllodes.

A very interesting member of the Scrophularineae is the shrubby Dermatobotrys Saundersii. The flowers are tubular, pink, and produced in whorls on the young wood. The species is a native of Natal, and is figured in *Bot. Mag.*, t. 7,369. The plant is inclined to be "leggy" and in a state of nature it may grow on the ground or be epiphytic, on trees, indeed the description accompanying the *Bot. Mag.* figure records it as "growing normally on trees."

The family Ternstroemiaceae furnishes us with an interesting plant at this season of the year. This is Eurya symplocina, a native of the Himalaya. It is scarcely an ornamental plant, the flowers being practically inconspicuous. They are small and white, or greenish-white, and carried in clusters sessile on the branches. They are found on the old wood, not on the shoots of the current season's growth.

An attractive bulbous plant in flower is Haemanthus albiflos. This species is of dwarf habit, with handsome, broad, dark green leaves, which show off the pure white of the perianth and the golden stamens to perfection. In Peristrophe speciosa we have a much-prized representative of the Acanthaceae. It is treasured either as a pot plant for decoration or for planting out in greenhouse borders, and its pink flowers are welcome at this time of year. Another valuable plant for pot culture and which may be had in flower at this season, is Tibouchina semidecandra. This species, sometimes known as Lasiandra macrantha, is a native of Brazil. T. semidecandra is almost as attractive for its foliage as for the fine purple flowers, which are its crowning glory. A very fine effect may be produced by training this plant up a pillar, as is done at Edinburgh, where its fine flowers may be seen over a lengthy period.

In the stoves, a very fine display is made of the red fruits of Pleuropetalum costaricense. The fruits are produced terminally, in great clusters, and contain a large quantity of small, black seeds. The Melastomaceae once again furnishes us with an attractive flowering plant in Centradenia floribunda, a species of compact habit, with purplish leaves, and pale, pinkish-mauve flowers. This is a valuable plant for pot culture. Another plant, useful for the same purpose, is Coleus thrysoideus, which produces spikes of pale blue flowers.

Foliage plants, of course, are valuable at this season, also Begonias of the Gloire de Lorraine type, besides Euphorbia (or Poinsettia) pulcherrima, which, according to D. T. Fish, was introduced into cultivation through the medium of the Royal Botanic Garden, Edinburgh.

In the Erica house, Epacris Model is flowering, and is a plant of upright growth, reaching a height of about two-and-a-half feet. The slender growths carry a profusion of pink flowers, which give the plant quite a distinctive appearance. It contrasts with the more prostrate habit of Epacris Eclipse, the flowers of which are red and white.

Before drawing these notes to a conclusion attention may be directed to a plant now in flower out-of-doors. This is Arctostaphylos Manzanita, a native of California, but it grows outside all the year round in Edinburgh, although not in a part of the garden open to the public. It enjoys some slight protection from the force of the winds, and is at present upwards of six feet in height. It is evergreen, the leaves being dark green and tough. The flowers are white, very faintly flushed with pink. This plant is usually at its best about the first of January, and is admired by all who see it. *Robert H. Jeffers.*

MR. F. KINGDON WARD'S EIGHTH EXPEDITION IN ASIA.*

XXIII.—IN POME.

THE junction of the two big rivers was a milder affair than we had expected, though there is doubtless more turmoil when both are in flood: for the summer rise here is about forty feet. The Tsangpo rushes down at a fine pace, and the Po-Tsangpo, also flowing in a gorge, hits up against it with considerable force, but at a rather acute angle. Both gorges are, on the whole, well-timbered, though the smooth, vertical cliffs are often necessarily bare. Above the waters, on either side, are terraces, with cultivation and villages. It is above 8,000 feet that the most extensive forests and the biggest trees are found; between 8,000 feet and 11,000 feet, the southern slopes of the eastern Himalaya are covered with a heavy pall of mixed forest. Above this comes the alpine zone. Although in the region of the gorge we never quite reached the alpine zone, it begins at no great height, the Abies forest ceasing abruptly at about 11,000 feet. This was what we found even at the Doshong La, where the main Himalayan range is so low that the monsoon rains sweep right over it with scarcely a check. The enormous volume of snow which falls in the eastern Himalaya is largely responsible for the depressed snow line and consequent low alpine region. In fact, at the Doshong La, we found all the best alpine plants between 11,000 and 12,000 feet, while several dwarf Rhododendrons crept down even lower. Their endless variety I have already stressed.

North of the Tsangpo and west of the great gorge, the variety is infinitely less; there are few dwarf Rhododendrons—not more than five or six species in fact, and those of the 'Lapponicum' type predominate. And yet the summer climate here differs in no respect from that of the Himalaya range proper, south of the river: that is to say, it rains almost without ceasing—more it cannot do. It is otherwise with the conditions in winter. In any speculation as to the reason for this bewildering multiplication of forms, therefore, account must be taken of the great accumulation of snow, which buries the alpine flora beyond recall, for at least seven months in the year; since where do we not find this snow, neither do we find so great a variety of flowers—at all events, of Rhododendron. In England, we must necessarily work our Rhododendrons overtime—nine or ten months a year instead of five. North of the river, but east of the gorge, however, we find these conditions to some extent repeated, and here, indeed, we find an alpine flora related to that of the Doshong La; for I found on the southern flank of the great snowy range which appears to be the Salween divide, a 'Campylogynum,' a 'Saluenense,' and a 'Sanguineum' Rhododendron, besides that missing link between the Himalayan and Chinese Primulas, a purple-flowered 'Sikkimensis.' It is therefore in this direction that one can most profitably follow the trail of the Sino-Himalayan flora. The mountain ranges present here a bridge between Pome and Burma, and, at the same time, act as a barrier between the Indo-Malayan flora to the south, and the steppe flora of Tibet to the north.

The Indo-Malayan flora penetrates far up the gorge of the Tsangpo, but does not cross the main axis of the Himalaya. It must be remembered that at the confluence we were not more than 5,000 feet above sea level, and in a sheltered gorge; incidentally, the lowest point we had reached for many months. Even in December it was almost uncomfortably hot in the daytime, making a penance of climbing; hardly surprising was it, therefore, to find ourselves in the midst of sub-tropical vegetation. We saw no Palm, save the Rattan, but there were half-a-dozen species of Bamboo, including a climber. A species of wild Banana grew to an impressive size; the stems were forty feet to fifty feet high, thirty-nine inches in circumference near the base, bearing leaves sometimes ten feet long and three feet wide. There was a grove of such giant Plantains on a steep, boggy-forested slope, just above the confluence, and the native hunters who accompanied us amused themselves by slashing across the stems with their knives, in order to hear the leaves tearing like brown paper as the unwieldy vegetables fell.

A small, creeping Ficus covered many of the tree trunks like Ivy: another species formed bushes on rocks, or in the boles of trees; a third and that in fruit, attained the dimensions of a small tree.

On the edge of the forest we saw some gigantic Thistles, eighteen to twenty-four feet high, with quite small heads of flowers, and a Codonopsis with bright purple fruits. Inside the forest the ground was often sprinkled with the gaping, scarlet capsules of a Curcuma, bristling with rows of white seeds, like milk teeth. I have already referred to a small, tree Viburnum, with large bunches of red berries; these the natives eat, but they are distinctly bitter raw, and would probably be better cooked. A species of Quince was occasionally seen in the villages, and the large fruit, though very hard, was edible, and would make excellent jam. Rice is not cultivated here, but is grown a short distance down the river. Amongst the Orchids, a large Cymbidium was fairly common, but it was only in bud; Dendrobium, Eria and Bulpophyllum were the genera most frequently met with, but none of these were in bloom either.

On December 18, we left the neighbourhood of the confluence, where we had spent over a fortnight botanising and searching for the more or less mythical falls, and started northwards up the Po-Tsangpo to rejoin our main body at Tongkyuk. We were now on the outskirts of the mysterious province of Pome, which lies north of the Tsangpo bend, and is drained by the still unexplored Po-Tsangpo and its tributaries. But it was no use our penetrating further into that difficult country now; it would need a full season's work merely to reconnoitre those valleys and mountains, and our best plan was to get home as quickly as possible with what we had got. At some future date, perhaps!!! We were once more on a good path, so that we made better progress.

---

* The previous articles by Mr. Kingdon Ward were published in our issues of April 12, May 17, June 21, August 9, August 30, September 27, November 1, 1924, April 4, May 9, June 6, June 20, July 4, July 18, August 1, August 15, September 5, September 19, October 10, October 24, November 21, December 5, and December 19, 1925.

It must be recalled that in penetrating the gorge of the Tsangpo we had passed right through the Himalaya. Hence, in order to regain the plateau, we had to cross them again, though where that crossing was to take place, we did not know. Eventually, we came to the conclusion that the Po-Tsangpo, which also flows in a gorge, likewise cuts through the main Himalayan axis; so that during the next few days, while marching up the river, we must have recrossed the Himalaya. This was more apparent from the change in the vegetation than from the physical aspect of the country. We soon reached drier regions, Pine and Juniper forest replacing the sub-tropical forests of the confluence. The disappearance of the big Tsuga, and of the big-leaved 'Grande' Rhododendron, was also significant. Ground Orchids in some variety took the place of epiphytic species, but in the deepest glens one still noticed large-leafed Araliaceae, and the prevalence of Ferns was notable. The Rhododendrons were 'Virgatum,' 'Arboreum,' 'Irroratum,' and a few others, the first-named occasionally in bloom.

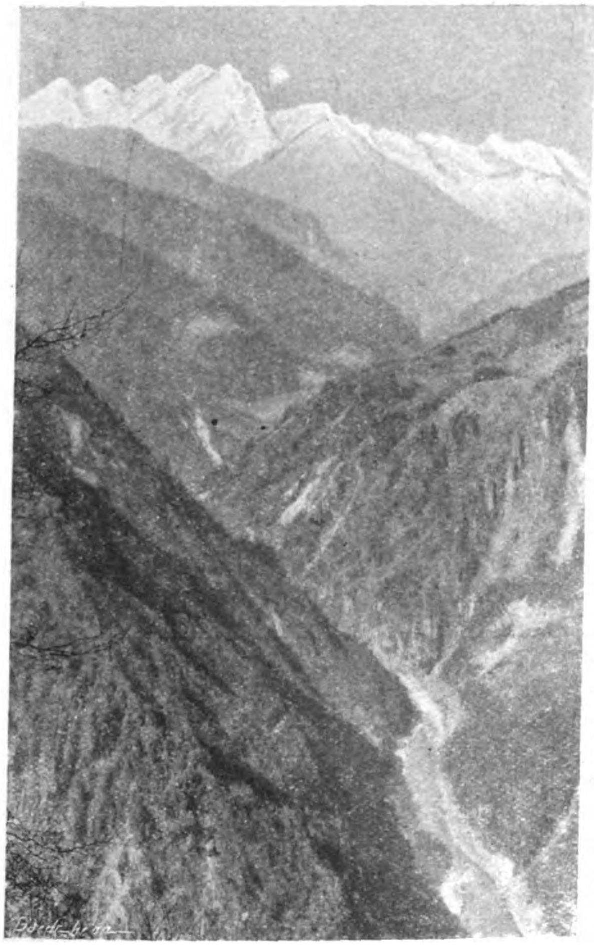

FIG. 3.—VIEW OF THE TSANGPO JUST ABOVE THE CONFLUENCE.

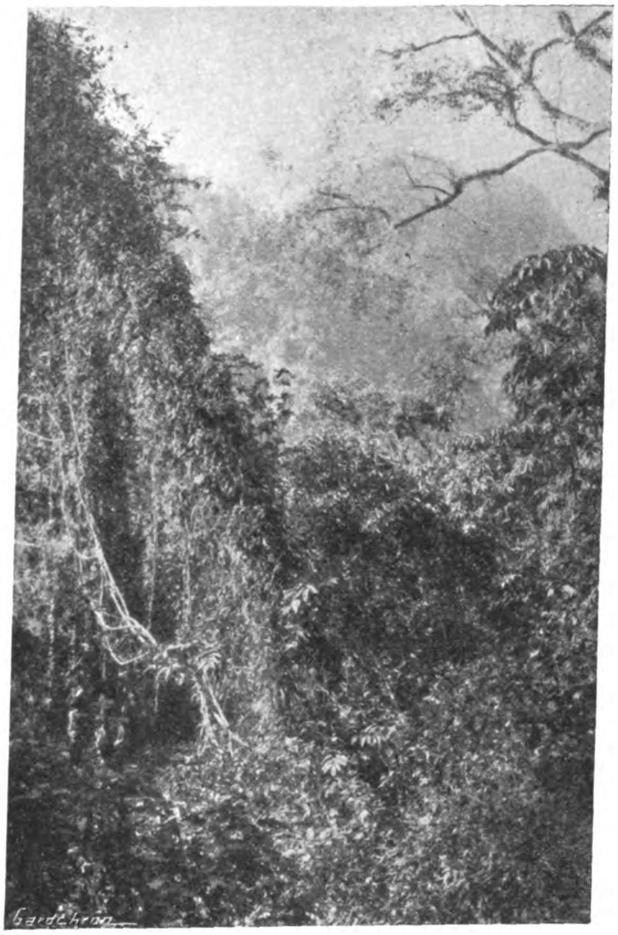

FIG. 4.—SUB-TROPICAL FOREST ALONG THE LOWER TSANGPO GORGE.

I have already referred to the big 'Martagon,' Lily of the Pine country. On the steep, grass-clad, sunny slopes above the confluence were scattered a number of Lilies, of which I collected some seeds; but if this was the pink 'Martagon,' it was, at any rate, much smaller than the Tongkyuk plant, never carrying more than three or four blooms.

Going down to Tongkyuk from the upper Rong, we had remarked a rapid change in the flora, plants of sub-tropical appearance replacing the alpine and sub-alpine species of the old glacier valleys. But ascending from below, the real sub-tropical vegetation died out even more quickly, till, after reaching the Rong confluence—nominally four days' march from the Tsangpo, but we had halted two days en route, and did not get there till December 23—we were already behind the Himalayan barrier again. In the course of this brief march we ascended only some 1,200 feet above the Tsangpo at Gompo Ne.

Much of the country, where it is not covered with Pine forest, as usual on sheltered slopes, or with mixed forest as in the deeper glens, is clothed with bush. Here you may see Deutzia, Philadelphus, Hypericum (H. Hookerianum or H. patulum), Spiraea, Salix, Eleagnus, Alnus, Buddleia, Ailanthus, Daphne, Cotoneaster, Berberis, Viburnum, etc., with a few climbing plants, as Ivy, Clematis, and a big, leathery-leafed Asclepiad. I noticed also a good deal of Mistleto, which shows a partiality for Dalbergia, and there were Violets in flower on the Ferny banks. There are two species of Buddleia, a large-leafed one found in the forest, and a smaller, flannel-leafed species growing on the sun-kissed screes. The flowers of the latter are violet, rather small, and in short, limp spikes, but the foliage is handsome. There are also two species of Berberis, one like B. nepalensis (?) with large, prickly, pinnate leaves, and slender, erect spikes of orange flowers—a plant of the mixed forest this; the other already referred to with beady, blue-black berries and clouds of gamboge flowers.

On December 23, we made a longish march, and, crossing the Po-Tsangpo by rope bridge at dusk, reached Trulung by torchlight. We were now on the main pack road between Tongkyuk and Pome. Next day we climbed a cliff and found ourselves by the Rong once more, though still below 8,000 feet altitude.

A good march on Christmas Eve brought us to a camping ground by the stream. We were still in Pine forest, but the weeping Pine of the lower valleys was now diluted with the short-needled, small-coned species, and before we reached Tongkyuk, the former was completely eliminated. We awoke on Christmas morning to find our blankets stiff with rime after 9° of frost. The sky was as clean and clear as a blue lagoon, and the sun shone brilliantly, as it had done for some days, and would continue to do till the next brief storm emptied itself over the hills. A short march brought us to a village set amidst mountains clothed with Pine and Bamboo; down by the stream every twig was encrusted with the amber beads of Hippophaë, or the coral of Cotoneaster. The Alders bore monstrous bunches of Mistleto, and on the steep rock chutes grew patches of scrub-Oak and spiny Ceratostigma, announcing that we were already beyond the regions of regular winter rain. The forest was now pure Conifer, Pinus Armandii, and a Scot's Pine on the sunnier slopes; Picea on the sheltered cliff. Only, three species of Rhododendron, the 'Virgatum,' the 'Arboreum,' and the 'Triflorum' were seen in the valley, though, of course, one would have met with plenty more higher up the slope. Thus the last vestiges of an Indo-Malayan flora quickly dwindled and disappeared.

On December 26, we covered the remaining ten miles to Tongkyuk, taking it easily, for despite the sharp frosts, it was quite hot in the middle of the day. Here we rejoined the main body, who, having heard no news of us for a fortnight, and, finding us long overdue, had almost despaired of ever seeing us again!

We now made instant preparations for the winter journey across the plateau. *F. Kingdon Ward.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.

Urgent Communications.—*If sent by telegraph, these should be addressed "Gard. Chron.," Rand; or by telephone, to Gerrard,* 1543.

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

LILIUM BROWNII.

IT is to be hoped that in their researches into the new plants of the present era, botanical and horticultural historians and investigators of the future may not be beset by the difficulties which so often face students of a genus in probing the history and synonymity of plants of bygone generations. And in view of the publicity a new plant obtains, nowadays, and the attention it receives from horticultural writers, it is hardly conceivable that all we know about plants of the present century will not be available to our children's children to the *n*th generation.

These reflections have been prompted by the failure of yet one more attempt to elucidate the history of L. Brownii at and before the time it reached this country. All we know about the Lily is that it was named after F. E. Brown, a nurseryman of Slough, who flowered the species for the first time in Britain in 1837. Miellez, another nurseryman, of Lille, to whom Brown had sent some bulbs in 1837, exhibited flowering plants of it at a flower show held by the Lille Horticultural Society in 1841, and paid Brown the compliment of coupling his name for ever with the Lily* Incidentally, this is an apt illustration of the haphazard way some plants come by their names.

It is reasonable to suppose that in the case of a noble Lily like this, Miellez would have obtained from Brown all the information he could about the origin of the plant; but if he did, not a word of it has come to light; and until something definite is discovered as to the source of Brown's bulbs, the place and country of their origin will remain conjectural.

It did not take the Dutch and Belgian nurserymen long to appraise the merits of L. Brownii, and not being difficult of increase by the bulblets which cluster in quantities at the base of the stem, the species soon found its way into commerce, and has remained there without serious interruption ever since. What is, perhaps, more to the point, is that it is apparently the same in all its parts as it was nearly a hundred years ago. eloquent testimony to the virtues of propagation of Lilies by root or bulb offsets—practically the only means available, as L. Brownii seldom ripens seed, at any rate, in Europe.

L. Brownii is characterised by the long, arching, dark green, lanceolate leaves, so well shown in Fig. 6, by the chocolate colour of the perfectly formed flower bud and the classic shape of the flower, which might almost have been carved out of marble. When the bud first opens it reveals an ivory lining to the trumpet, but as the petal-tips slowly turn back this changes to snow-white, in coldly beautiful, glistening contrast to the rich tint of the outside of the flower. The long, regular leaves, the form, colour and port of the flowers give the species an air of dignity and classic beauty not found in the genus except now and again in exceptional examples of L. Sargentiae.

Though not a constant one, another peculiarity of L. Brownii is the bulb, of which the unusual shape is well shown in the reproduction (Fig. 7, p. 13) of the drawing of it in Dr. Wallace's *Notes on Lilies.** It will be seen that the scales are hollowed out at the base, and as these fit tightly one over another, the doctor advanced the ingenious theory that moisture which finds an entry at the flat apex where the scales are looser, lodges in the cup-shaped depression at their base and causes the decay which is a troublesome feature in the cultivation of the species.

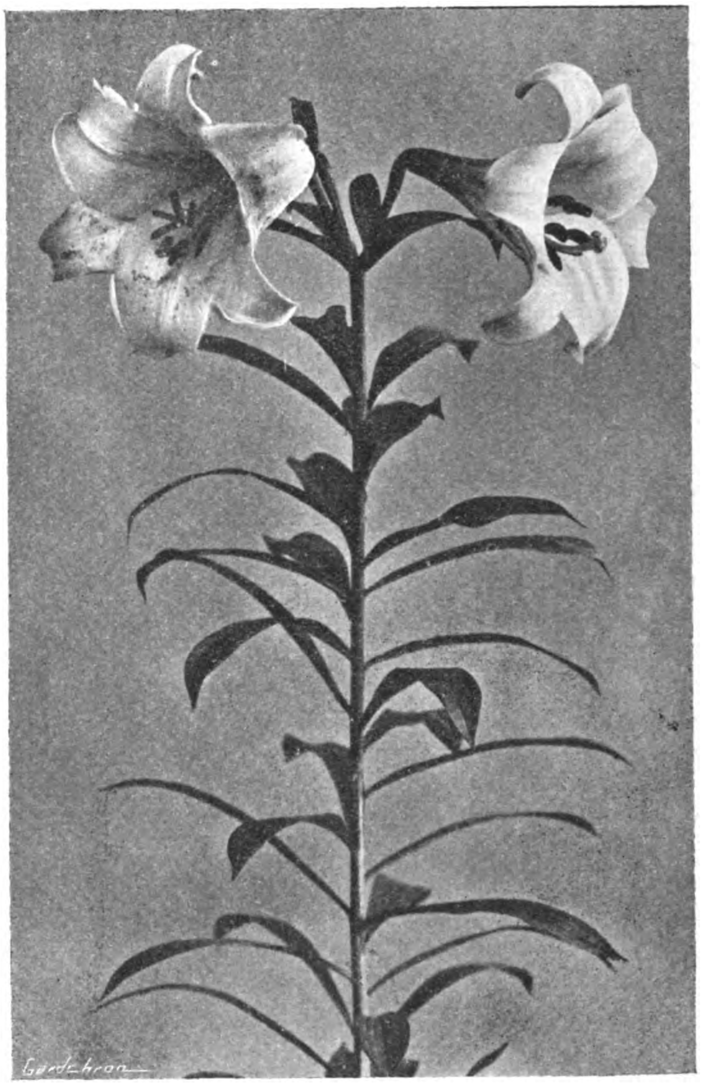

FIG. 5.—LILIUM BROWNII VAR. COLCHESTERI.

Although L. Brownii has been cultivated commercially for so long by the Dutch nurserymen in the sands of Holland, it is undeniably difficult to manage in this country. To bring bulbs to saleable size in a nursery and then dispose of them is a very different matter from the subsequent cultivation of such bulbs in a garden. The writer had several isolated specimens of it in his garden for sixteen years and though they flowered annually, none showed any tendency to increase: they varied a good deal year by year, too, sometimes throwing one flower, sometimes three, and in a horticultural sense their annual appearance and behaviour was always a source of anxious anticipation.

The classic example of the successful cultivation of L. Brownii in Britain is in the wood at Hillbrook, Iver Heath, Buckinghamshire, where the late Sir Henry Yorke succeeded in establishing a colony of the species (see *Gard. Chron*, 3rd series, vol. LXIII (1918), p. 110, Fig. 50). The prosperity of this colony varied from year to year according to the season, and contingencies such as the ravages of mice, etc., but over a series of years the bulbs multiplied to such an extent that it was occasionally necessary to thin out the offsets. The soil is a rather holding but naturally drained loam, on the crest of a bank facing east and partially sheltered. There are, doubtless, other established colonies of the species in gardens, but the writer has no knowledge of them.

The relationship between L. Brownii and the Lily called L. japonicum colchesteri has been of interest to students since the former Lily first appeared. The so-called L. japonicum

A HYBRID NAEGELIA.

colchesteri reached this country in 1804—thirty years before L. Brownii—having been received at Kew from Canton. Aiton, who named the Lily,[*] confused it with L. japonicum, but it was not till 1875 that the varietal name, colchesteri, was added.[†] Before and after that many other names were bestowed on the plant, and few Lilies have had such a confused synonymity.

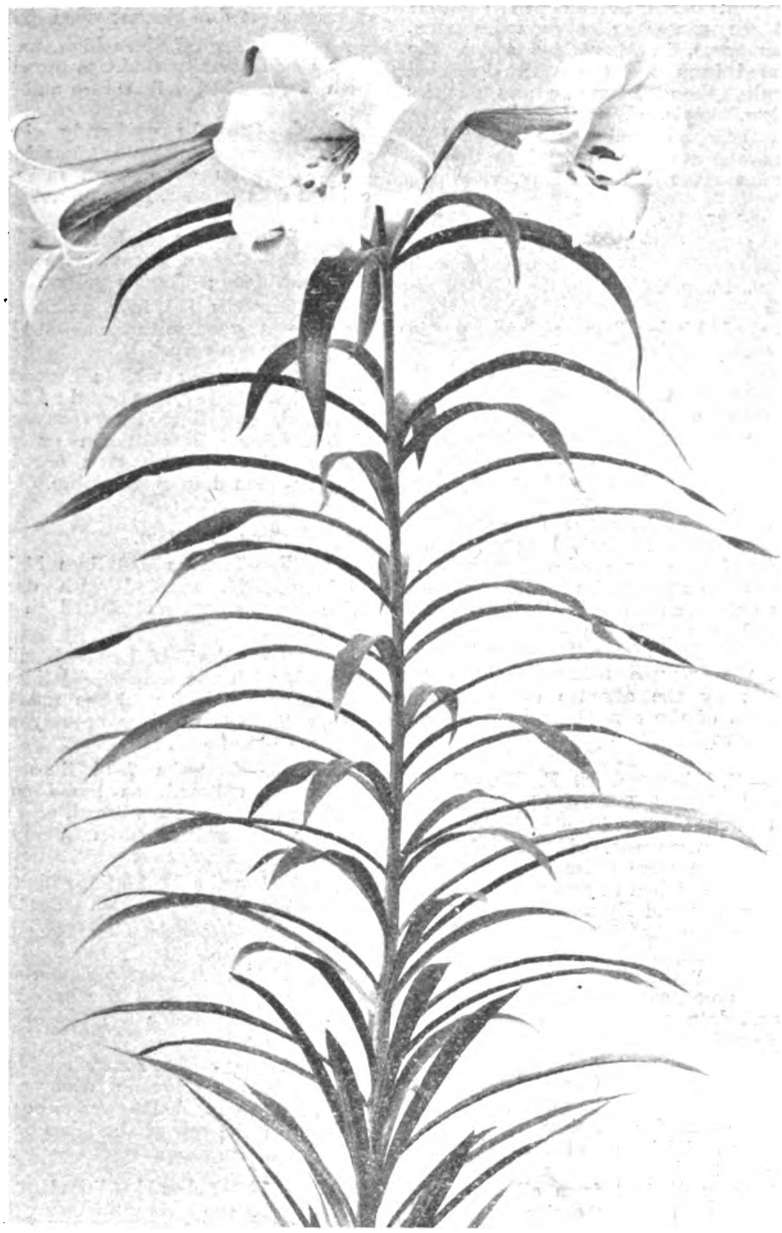

FIG. 6. LILIUM BROWNII.

But as the Lily has no connection with L. japonicum and seems to be closely related to L. Brownii, there is much to be said for the suggestion advanced by E. H. Wilson[‡] that it should be renamed L. Brownii, with the varietal name colchesteri attached.

This Lily has a wide range through the temperate regions of China, and Farrer seems to have found it in Burma: it probably finds its way into the collector's knapsack more often than other Chinese Lilies; and, at any rate, there is no lack of it in herbaria. Though seldom really perennial, it has been grown in British gardens for many years, but always from bulbs imported from Japan, where the Lily is cultivated for market under the name of L. Brownii var. odorum. It is one of the many plants of Chinese origin which gardeners have unwittingly come to regard as purely Japanese, and it was not until E. H. Wilson found the wild plant that the truth became known. But for the spread of botanical knowledge about new plants, already referred to, L. Henryi might some day prove a parallel case, for though entirely a Chinese species, it has for some years been cultivated in Yokohama for sale.

The temptation to regard L. japonicum colchesteri as the wild type of which L. Brownii, of Brown, is a cultivated form, is strong, and if that view were accepted the logical procedure would be to rename it L. Brownii, and reduce Brown's Lily to the position of a variety, as, indeed, it may be. But, no doubt wisely, botanists are slaves to convention, and as Brown's Lily has the right of precedence to his name, it will doubtless stand. Moreover, no one knows whether it really is a cultivated form of the wild Lily, or itself a good wild species; if the latter, it must assuredly have a very local station.

The exact relationship of the two Lilies has not been determined. Elwes[*] makes no bones about it, and taking a characteristically broad view, refers the two to one species. Botanically, they may be one; horticulturally, they are very different, though they sometimes have a strong character in common—the bulb. The leaves are different, and so are the flowers in form, colour and scent. Dr. Wallace, who made a careful comparative study of a batch of the two Lilies in growth and left lucid notes of his observations, likens the fragrance of L. Brownii to that of L. longiflorum, and of L. japonicum colchesteri to that of the Cape Jessamine,[†] a difference not only in quality but in strength. Incidentally, Farrer found the scent of L. japonicum colchesteri "overpoweringly sickly and sickening."[‡]

The anthers in Brown's Lily are of an appropriate dark brown colour: in the other they are light brown: in L. Brownii the stem is a bronzy-brown, with the leaves beginning about eight inches up: in the other it is almost glaucous green, as are the leaves, which begin close to the ground. When Brown's Lily first pushes through the earth the stem is a rich bronze point; the other is light green. None of these differences may be of scientific value, but they count horticulturally, and a point which emerges from extended observation of the two Lilies is that while L. japonicum colchesteri varies in many ways, L. Brownii is fixed.

There is some hope that if Brown's Lily is a wild plant, its habitat may yet be discovered, for Dunn and Tutcher[§] included it in their list of the Hongkong flora as "on the hills among grass, Hongkong; Lantao Island, Hongkong, New Territory"; they may possibly have confused it with L. longiflorum, which seems to be wild in Hongkong, but that is hardly likely, and plants raised by the writer from seeds sent to him by Mr. Tutcher some years ago have proved much nearer to Brown's Lily than to L. japonicum colchesteri. At the time the writer had little doubt the plants were the true species, but there seems a doubt as to the origin of the seeds, and they may have come from plants cultivated in the Botanic Garden at Hongkong. It was not possible to clear up the point before Mr. Tutcher's death, so that there is still a doubt as to the locality of the plant.

A remarkable point about L. Brownii is that it never seems to ripen seeds in Britain. Elwes[¶] never saw a capsule, nor, in twenty-five years of close observation, has the writer seen one. Seminal propagation might clear up the doubt as to the relationship between the two Lilies, and until we have definite evidence, no one is entitled to assume that L. Brownii is or is not a wild plant. Under cultivation it has not, apparently, altered in ninety years, and though, as already explained, that may be due to the method of propagation, we are entitled to regard it as very much the same now as when Brown first received the bulbs so long ago. *A. Grove.*

CLERODENDRON FALLAX.

PLANTS of Clerodendron fallax raised from seeds sown early in the previous year and which have flowered during the autumn should now have their spent flower spikes removed and be placed near to the roof-glass at the cooler end of the stove, allowing them several weeks' rest, keeping them only moderately moist at the root. So soon as the days begin to lengthen the plants may be re-potted and re-started into growth in heat, with a view to flowering them a second time during May and June. *F. J. C.*

MESEMBRYANTHEMUM.

(*Continued from vol. LXXVIII, p.* 500).

37a.—C. tantillum, N. E. Br.—Growths as first developed after importation, 2-4 lines high, 2½-4 lines broad and 2-3 lines thick, some of them smaller, obconic, faintly or dis-distinctly notched (somewhat as in type M), and faintly ridged at the top, with the orifice ½-¾ line long, having gaping lips; surface smooth, glabrous, green, not at all glaucous; the orifice area is broadly elliptic or orbicular and pallid, surrounded by dark green or at the sides (where the marking is slender) purplish; at each end of the orifice the dark marking enlarges into a large, irregularly triangular patch, on the ridge on each side of the orifice is a purplish or dark green dot or short line, and thinly scattered over the top are also from 2 to 9 other small dots. Calyx much exserted, 4-lobed, membranous, whitish, with the lobes tipped with reddish or greenish hue; tube 2 lines long; lobes ¾ line long, ovate, obtuse. Corolla (a dried flower only seen) probably 5-6 lines in diameter; tube exceeding the calyx, about 3½ lines long; petals magenta-purple; no staminodes or inner petals at the mouth of the tube. Stamens numerous, in 4 series at the throat of the corolla-tube, the two upper series exserted, yellow. Style 3½ lines long, slender, attaining to the mouth of the corolla tube; stigmas 4, about ⅓ line long, yellowish. Capsule 1¼ line in diameter, quadrangular, with 4 valves and cells, thin, pale brown; each valve with one central, honey-coloured, expanding keel and broad, membranous, spreading, marginal wings. Seeds minute, ¼ line in diameter, compressed, somewhat pear-shaped in outline, smooth, pale brown.

Little Namaqualand: Vicinity of Steinkopf, Meyer! Marloth 6512!

This appears to be allied to C. minusculum, N. E. Br., although quite distinct from that charming species.

26a.—C. Taylorianum, N. E. Br.—Growth 4-7½ lines high, 3-7 lines thick and 3½-5 lines broad, circular or elliptic in outline at the flattened or transversely depressed top; orifice ¾-1¾ line long; surface usually purplish-green on the sides and dull greyish-green on the top, marked with blackish-green dots. Flowers unknown.—Mesemb. Taylorianum, Dinter in *Fedde Repert., Beiheft (Succulentenforschung in Sudwest Afrika)* v. 23, p. 58 (1823); and Dinter and Schwantes in *Zeitschr f. Sukk.* v. 2, p. 27 (1925).

Great Namaqualand: Klinghardt Mountains, Dinter 3872.

This species is unknown to me.

15.—C. viridicatum, N. E. Br. var. punctatum, N. E. Br.—Growths as in the type, but of a somewhat greyish-green, with the sides often purplish-tinted and the top thickly sprinkled with very small dots of darker green, not confluent nor arranged in lines except sometimes along the obscure keel, and the orifice somewhat indistinctly outlined with similar dots.

Laingsburg Division: near Grootfontein Peers!

I have had this variety under cultivation for many years but have not seen its flowers, and find that it is fairly constant in the character of its dotting, by which alone it can be distinguished from the type, and as the typical form often has some of its growths more or less dotted, I have no doubt that it is a mere variety of that species.

In *Gard. Chron.*, vol. LXXI, p. 361, I have wrongly placed this species, for it should have been placed after C. pisinnum, on p. 214, as the surface is covered with a very microscopic puberulence, and is faintly velvety to the touch.

11a.—C. Whettsteinii, N. E. Br.—Growths 6-9 lines high, 10-15 lines broad and 10-12 lines thick, broadly obconic, circular or elliptic in outline at the truncate flattish top, which often overhangs the sides (type H); orifice 2-2½ lines long; surface smooth, glabrous, glaucous-green, faintly and rather minutely dotted with darker, and the orifice outlined with darker green. Calyx usually and sometimes the ovary exserted, 4-6 lobed; tube 3-3½ lines long, 1½ line broad, greenish; lobes 1-1½ line long, oblong, obtuse, reddish or green. Corolla 10-15 lines in diameter, expanding in daytime irrespective of sunshine or dull weather if the temperature is warm enough, and lasting about a week; scentless; tube 4-5½ lines long, about as long as or longer than the calyx, whitish; petals numerous, in 2-3 series, widely spreading and closely overlapping one another, 4-7½ lines long and ¾-1¼ line broad, notched at the obtuse tips, bright rosy-magenta; staminodes none. Stamens numerous, in about 4-5 series, the upper exserted from and the others included in the corolla-tube; filaments and anthers bright yellow. Style about 5-7 lines long, included in the corolla tube or exserted 1-1½ line beyond the stamens, divided at the top into 4 stigmas about ¾-1 line long, very pale yellowish.

M. Wettsteinii, Berger, *Mesemb.* p.p. 285, 288, fig. II. (1908); Schlecter in *Engl. Jahrb.* v. 45, p. 229; M. truncatellum, Othmer in *Gartenwelt*, v. 11, p. 301, with fig. (1907), not of Haworth.

A native of Little Namaqualand, precise locality unknown, Miss Phillimore!

Described partly from a portion of the original plant described by Berger, the locality of which is unknown, and partly from a plant of the same species sent to me from Little Namaqualand. My two plants are identical in every particular, except that one has a long, exserted style, 7 lines long, while the other has the style included in the corolla-tube and about 5 lines long, being, in fact, long and short-styled forms of the same species. But whether the length of the style varies in different years on the same plant, as I have noticed it to do in C. bilobum, I am unable to say.

C. Wettsteinii differs from C. Pearsonii by the surface of the growths being faintly dotted on the top; by the absence of staminodes at the mouth of the corolla, and by the very much longer style.

21a.—C. Wiggettae, N. E. Br.—Growths of imported plant 3-5 lines high and 2½-6½ lines in diameter, obconic, elliptic to circular in outline, and when received in their shrivelled, resting condition were quite flat on the top, becoming convex when in growth (intermediate between types D and E), with a central orifice about 1 line long that is not at all depressed, smooth, glabrous, dull green (perhaps grey-green in nature), thickly marked with blackish or very dark green, separate (not at all confluent) large, round dots (which vary from ¼-½ line in diameter) on the top, and the orifice outlined with dark green or purplish; the sides are more or less tinted with dull purple. Only dead flowers seen which demonstrate that the plant is a Conophytum, but are unfit for description.

Oudtshoorn Division: at Hazenjacht, Mrs. I. Wiggett 4!

This is very distinct from all other species that I have seen, being easily recognised by its unusually large, separate dots, which are not disposed in any pattern, but are equally scattered over the top, and by the orifice not being at all depressed. I have much pleasure in naming it after its discoverer.

KEY TO THE SPECIES THAT ARE MORE OR LESS TWO-LOBED AND USUALLY COMPRESSED AT THE TOP OF THE GROWTHS.

1.—Surface-cells as seen with a lens projecting as microscopic points, scarcely hairs, and faintly harsh (scarcely velvety) to the touch, distinctly or indistinctly dotted. (See also C. Meyeri, which really belongs to this group but is not two-lobed at the top). 2

Surface-cells as seen with a lens flat or convex, not projecting as microscopic points, smooth, or in C. exsertum slightly harsh to the touch. 4

2.—Growths 1-2 inches high and ¾-1 inch broad, with the notch 3-6 lines deep; lobes equal, flat on the inner face; dots very conspicuous. **apiatum**

Growths 3-18 lines high and 3-10 lines broad, with the notch ½-5 lines deep; lobes equal or unequal; dots usually evident but not very conspicuous. 3

3.—Growths 9-18 lines high and 5-10 lines broad; lobes rounded on the inner face; glaucous-green or whitish-green. **albescens**

Growths 3-12 lines high and 3-8 lines broad, usually taller than broad; lobes very short or flattened on the inner face; green or somewhat glacous-green. **hahlenbergense**

Growths 4-7 lines high, and 4½-6½ lines broad, usually about as broad as tall, with the notch ½-1 line deep and its faces flat. **quaesitum**

4.—Growths uniformly glaucous-green without dots or other markings. 5

Growths either with more or less evident dots or markings, or not glaucous-green. 6

5.—Growths 1½-2 inches high and much taller than broad, with the notch 4-9 lines deep; flowers yellow. **bilobum**

Growths ½-1 inch high and nearly or quite as broad, with the notch 1½-2½ lines deep; flowers rosy. **nuciforme**

6.—Flowers white; growths 5-16 lines high and 3-7 lines broad; lobes mostly unequal, ¾-3 lines long, convex on the inner face; light green or yellowish-green, with or without a few indistinct darker-green dots on the lobes. **Roodiae**

Flowers red 7

Flowers yellow. 8

7.—Growths 5-8 lines high; lobes sub-cylindric, marked with dark green lines on the top, and dotted on the lower part. **turrigerum**

Growths 7-15 lines high and 5-8 lines broad, with the notch ½-3½ lines deep or sometimes absent; lobes not cylindric; dots distinct, no lines or only a red one on the top of each lobe. **gracilistylum**

8.—Growths 7-14 lines high and 6-10 lines broad, as broad as high or not much taller than broad, of a somewhat dull bluish-green; dots usually not particularly conspicuous. **Eliskae**

Growths 12-21 lines high and 6-10 lines broad, always much taller than broad. 9

9.—Growths pale glaucous-green or whitish-green, slightly harsh to the touch, but without microscopic points or hairs; ovary exserted and the expanded flower rising much above the top of the lobes; stigmas red. **exsertum**

Growths of a somewhat bluish-green; smooth to the touch; ovary not exserted and the expanded flower either below the level of the top of the lobes or not rising much above them. 10

10.—Lobes 1½-4 lines long, somewhat obtuse at the apex; stigmas red. **cauliferum**

Lobes 3-6 lines long, obliquely acute at the apex; stigmas yellowish. **sororium**

The plants of this group seem to be chiefly natives of Namaqualand, where there seem to be several closely-allied species. I have a few others, but they are not at present in a fit state for description.

51b—C. albescens, N. E. Br.—Stemless. Growths 9-18 lines high, 5-10 lines broad, and 4-8 lines thick, cylindric-oblong, compressed, and 2-lobed at the top, with a notch 1-5 lines deep, and the lobes usually equal, but on short-lobed plants often unequal, rounded on the inner (or notch) face; surface covered with a pubescence of microscopic points, scarcely hairs, and somewhat harsh to the touch, whitish-green or pale glaucous-green, somewhat indistinctly dotted with darker green and with a short red line on the tips of the lobes. Ovary more or less exserted. Calyx 5- (or perhaps sometimes 4-) lobed; tube 2¼ lines long; lobes 1 1¼ line long, oblong, obtuse, green or reddish. Corolla about 1 inch in diameter, expanding in daytime; tube 4-4½ lines long, slightly longer than the calyx, somewhat funnel-shaped above, yellow: petals about 4 lines long, ¼-½ line broad, linear, subacute or obtuse, bright clear yellow, shining. Stamens numerous, in about 4 series, most of them well exserted from the corolla-tube, yellow; filaments 2–3 lines long. Style 3 lines long, greenish, stigmas 6, about 2½ lines long, pale reddish. Top of the ovary conical, green.

Little Namaqualand: locality unknown, but possibly from near Chubiessis, as it was sent by Professor Pearson along with C. cauliferum.

This very distinct species is know by cultivators of these plants as "Heath's seedling," and Dr. Rodier Heath informed me that he raised it from seeds taken from a capsule that was upon one of the plants sent to Kew by Professor Pearson along with C. cauliferum. The plant died, and the seedlings raised from it by Dr. Heath now exist in several collections. I have cultivated it for many years without succeeding in flowering it, and am indebted to Mr. T. M. Endean, of Laindon, Essex, for the loan of a plant in flower, from which the above description has been made. *N. E. Brown.*

(*To be continued.*)

FLORISTS' FLOWERS.

NEW CHRYSANTHEMUMS OF 1925.

DURING the autumn of last year, thirty-six varieties of Chrysanthemums were honoured by the Floral Committee of the National Chrysanthemum Society with first-class certificates, and about a score of these also received the Award of Merit of the Royal Horticultural Society. One variety not placed before the committee of the former was selected for recognition by that of the latter. It cannot be said that the number is a large one as compared with some former seasons, but it indicates a high standard of excellence, for the general presentation of seedlings did not go below the average of recent years.

Some idea may be gained of the popularity or favour of certain types or classes of Chrysanthemums if it be mentioned that eleven varieties were early-flowering—seven of these being put up in spray form as opposed to disbudded blooms; eleven were of the decorative, or market type; four were exhibition Japanese varieties; eight were single-flowered, one incurved, the other of Anemone form. For the first time, probably, the medium-sized blooms had dominated the giants. By this it must not be inferred that show flowers are on the wane in the estimation of growers, but it does certainly point to improvement in commercial varieties. The comparatively few single varieties that were honoured go to show that it is no easy matter to raise a good one, notwithstanding the ease in obtaining seeds of this class.

It is interesting to point out that the greater number of successful novelties were seen both early in the season and late, those of the beginning and the end about equalling each other, and these "earlies" and "lates" comprised two-thirds of the whole. Thus it would seem that the powers that be guide us in relation to present needs, knowing that mid-season varieties are by no means scarce and will take care of themselves, as it were. This must surely be the standpoint of the market grower who does not wish to add to the mid-season glut of flowers.

Referring to the early-flowering sorts, two of the disbudded ones named Fire Crest and Lichfield Peach are in commerce already, the other two are Crimson Circle and Mayford White; both of these are gains in their respective colours. In spray form, Phoenix and Brightness are in the lists of traders. Cranford is deep yellow, and Cranford Cream much lighter; both are excellent. Shirley Pride mauve-pink; Berengaria, a rose shade, and Chancellor, fawn, represent capital new sorts.

The giants of the year—I mean additions to the show sorts—are: J. Baxter, a neatly recurving bloom of an amaranth shade, with attractive, coloured florets in the centre; Mrs. A. Holden, crimson, with bronze shading and of graceful, drooping form: Ajax, of big, solid, incurving style, deep yellow, with carmine suffusions inside; and Belle Chinoise, a specially rich yellow of recurving shape. The incurved variety named Ondine is in commerce; and Mary Godfrey is an attractive blush-pink Anemone-flowered form, with deeper coloured outer rays; this variety is large for the type.

The single-flowered sorts arranged in order of their presentations include Jessie McNab, a yellow of good size and substance; Mrs. F. Brill, already in the lists: Alert, a good crimson; Ruby Ray, neat, crimson, of market style; John Langford, clear yellow: Crimson Dawn, particularly good; Incomparable, rich purple, with a white zone, a first-rate sort for show purposes; and Zenith, deep orange, a variety of medium size.

Similar order is observed in the case of the decorative, or "cut-flower" sorts as to time of exhibiting, and all except the two first-named won honours subsequent to the great exhibition early in November. Mayford Yellow is rich in colour and the flower remarkable for its lasting qualities; the crimson Mrs. R. H. Felton, neat in petal and form; Clio, crimson terra-cotta; Enton Beauty, crimson-maroon; Ra, neat in formation and of yellow colour: Jewel, golden-bronze, of good shape: Delicata, a shapely, pearl-pink bloom of fine substance; Pink Prize, a deep shade for the time of year; Bianca, reddish-bronze: Phryne, a very pretty flower of soft pink colour; and Omega, golden-apricot, of the incurved type.

In the estimation of the writer, the above-named novelties constitute a set well above the average merit, while not a few varieties which failed to secure an award when shown are worth a trial. The additions to late-flowering varieties are numerous, and in strength of growth as well as colouring and substance of blossom the new-comers will be found most acceptable. Raising seedling Chrysanthemums, the double ones more especially, calls for great care and perseverence in our changeable climate: but it is not a matter in which those with the greatest facilities are the most likely to obtain the best results. *H. S.*

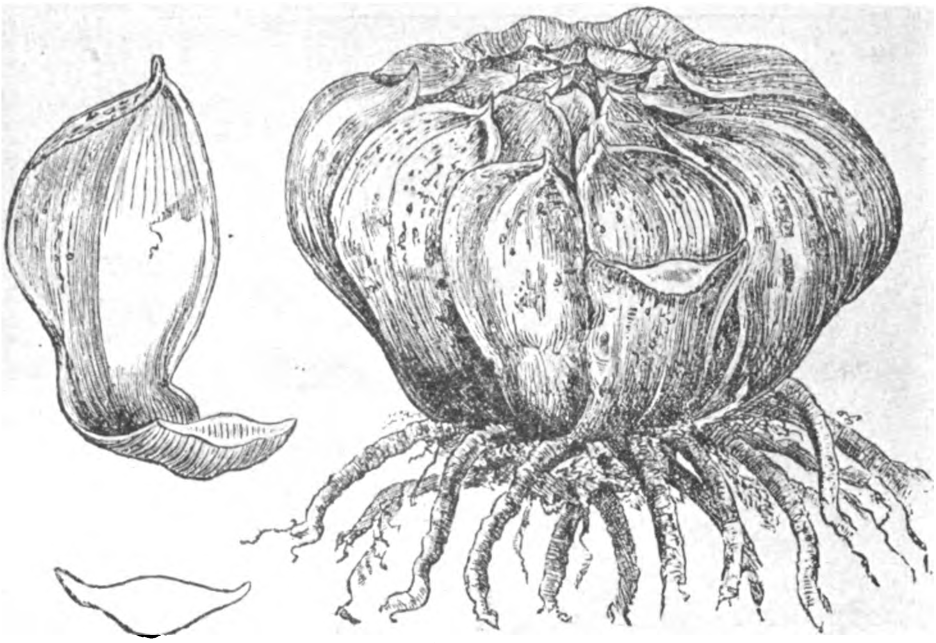

FIG. 7. BULB OF LILIUM BROWNII.

(see p. 10).

HARDY FLOWER BORDER.

PAPAVER UMBROSUM.

THE annual Papaver umbrosum produces self-sown seedlings in abundance, and is a plant of great beauty. Its height is generally given as eighteen inches, but it is frequently considerably less, except in good soil, and, when dwarfer, it loses none of its beauty by its lesser stature.

It has large flowers of a most attractive shade of deep crimson, decorated with black blotches, which I feel confident no one would desire to eliminate, as so many have sought to do in the case of the flowers of Papaver orientale.

As a Poppy to scatter broadcast among other flowers, or to naturalise in a semi-wild spot, P. umbrosum will secure the affection of its owners once they have become acquainted with its charms. It is now many years since I first obtained seeds and sowed them in a border. The seedlings grew well and flowered in due course, and they left a numerous family of descendants, which in turn presented me with a plentiful crop of free-flowering plants, which were all the finer from being self-sown. This packet supplied me with plants for at least twenty years, but one arctic winter, which killed practically all the self-sown seedlings of hardy annuals in my garden, destroyed my hopes for the following year by the destruction of all my seedlings.

However, seeds which had not germinated in the autumn came up in the following season, so that I was not utterly bereft of this charming Poppy. *S. Arnott.*

ASTER CALIFORNIAN GIANT.

THOSE who require an Aster, suitable alike for bedding-out and for cutting, will find the Californian Giant type highly satisfactory. The stems of the plants are long, and the flowers last well in water.

The varieties Deep Rose and Light Blue are gems, being superior to any others which I have grown.

These sorts were only recently sent out by Messrs. Dobbie and Co., and may be likened to the Giant Ostrich Plume Asters. The flower stems are often over eighteen inches in length. Consequently the effective arrangement of the blooms in vases is an easy matter. *Charles Hodgson.*

BULB GARDEN.

BULBOUS PLANTS FOR SHADY SITUATIONS.

THERE is a fascination in any kind of vegetation that will thrive and flower in shady places, such as under trees or in borders shaded by tall buildings. Hardy Ferns are very valuable in providing greenery or foliage in shady spots, and further interest may be added if suitable bulbous plants are arranged in clumps between the Ferns. The hardy Cyclamens, which may be included amongst bulbous plants, are extremely beautiful in both flower and foliage and succeed beneath trees; they thrive better if a little lime rubble is incorporated with the soil. C. Coum has rosy-crimson flowers and olive green foliage. There is a pure white variety named album; C. europaeum has sweetly-scented, crimson flowers in autumn; C. hederaefolium (the Ivy-leaved Cyclamen), in shades of white and bright rose, has handsome, marbled leaves; C. ibericum has white and rosy-pink flowers in winter and spring; whilst C. repandum, a pretty Italian species with crimson flowers and olive green foliage, flowers from March to June.

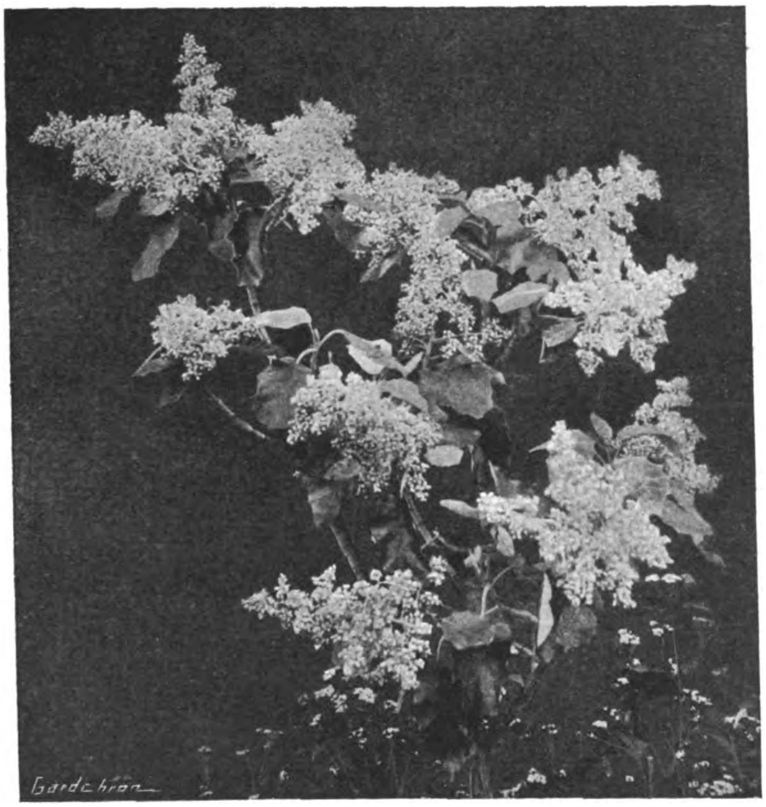

FIG. 8.—BRACHYGLOTTIS REPANDA FLOWERING AS A POT SPECIMEN.

In spring, the Erythroniums make a glorious display if planted in a mass, with their pretty, variegated foliage and Cyclamen-like flowers in various shades. The dwarf European species are old favourites and well-known, with flowers in shades of white, rose and purple. The American species and varieties are far superior to the European members, having taller flower stalks and numerous flowers of various colours. E. californicum is chrome-yellow; E. grandiflorum robustum golden yellow; E. Hartwegii, primrose; E. Hendersonii, pale lilac, with a purple centre; and E. Johnsonii, rose pink. Many have beautifully mottled or marbled foliage, above which stems varying from eight to fifteen inches tall bear from three to six large nodding flowers. These plants are extremely decorative when naturalised in shady situations.

Glorious as is the common native species of Anemone, A. nemorosa, the Italian species A. apennina, with large, bright blue flowers, and the Grecian species, A. blanda, with deep blue flowers are even more showy, and should be planted with a lavish hand in woods or copses, where they will quickly form dense cushions smothered with the daintiest of blue flowers during spring. Other suitable and showy kinds are A. nemorosa Allenii and A. n. Robinsoniana, in shades of blue, and A. ranunculoides, the yellow-flowering wood Anemone.

The Trilliums (Wood Lily or Trinity Flower) are interesting and exceedingly showy plants for moist and shaded situations. They should be planted in clumps to form colonies, and allowed to become naturalised. Their large, handsome, dark green foliage and three-petalled flowers are most effective for a long time. The most showy species are T. erectum, reddish purple; T. grandiflorum (Wake Robin), snow-white fading to blush with age; T. recurvatum, brownish purple; T. sessile californicum, creamy white; T. stylosum, rose; and T. undulatum (syn. erythrocarpum), snow-white, conspicuously spotted with red at the base. These Trilliums should be planted in a deep, moist, sandy loam containing plenty of leaf-mould. *W. Logan.*

ALPINE GARDEN.

ACHILLEA LEWISII.

WE are indebted to Mr. Clarence Elliot for his notes on Achillea Lewisii (vol. LXXVIII, p. 477). Among other points to which he refers is that of the name of A. Lewisii, and he also states that an identical plant appears under the name of King Edward. The point of its origin has puzzled me, and I am still uncertain as to whether the plants have been raised separately, or whether a different name has been applied to, say, A. Lewisii, from its being received from some source without a name. This has frequently happened with plants, and affords no end of trouble to many.

I have seen this yellow-flowered dwarf hybrid Achillea more frequently under the name of King Edward than under that of A. Lewisii, yet I feel disposed to accept the latter as the original name.

On the occasion of my last visit to the garden of the late Mr. James Whitton, at Bellahouston, Glasgow, where he had taken up the cultivation of alpines as a hobby after his retirement from the Directorship of the Glasgow Parks, I found this Achillea growing under the name of "King Edward," as I had seen it in other gardens. Mr. Whitton and I had a discussion about the name of King Edward with which we did not feel satisfied. I entirely agree with all that has been written by Mr. Elliot in favour of this hybrid Achillea. It far surpasses A. tomentosa, which one would accept as one of the parents. I think the other may be A. Aizoon, but it might well be some other dwarf Milfoil.

A. Lewisii, as I prefer to call this Achillea at present, until otherwise advised, is a most valuable rock plant, and is capital as an edging or front row plant for the border. *S. Arnott.*

PLANTS NEW OR NOTEWORTHY.

BRACHYGLOTTIS REPANDA.

THIS very interesting New Zealand shrub is seldom met with in gardens, but I venture to suggest it deserves to be grown as a pot subject for conservatory decoration. Although it has not proved sufficiently hardy to withstand our winters out-of-doors—except in a few favoured localities—a cool house is all that it requires for protection. The large, cordate, irregularly lobed leaves, are dark green above, and cottony-white tomentose beneath; as many of the leaves show their undersides the contrast is very striking.

The flowers are individually small, but are borne on dense terminal panicles; they are ivory-white, faintly scented, and although not especially beautiful, they give the whole plant a graceful appearance.

The accompanying illustration (Fig. 8) shows the freedom with which this species flowers, especially if its roots are confined in a comparatively small pot or tub. *C. F. Wood, The Warren Gardens, Hayes, Kent.*

[Brachyglottis repanda was fully described and illustrated in *The Gardeners' Chronicle* of June 15, 1895, from material obtained from Treso, Isles of Scilly. This species has been referred to in these pages on several other occasions, notably in our issue of July 18, 1908, when the late Mr. W. Fitzherbert described a large specimen, accompanied by illustrations (Fig. 9), which flowered out-of-doors at Kingswear, Devon.—EDS.]

TREE PLANTING FOR SHELTER.

THE benefits to farm stock and crops on exposed and high-lying grounds that are derived from a well-organised scheme of tree planting, can hardly be overrated. A mountain farmer on Lord Penrhyn's estate in Wales, whose lands extend far up on a spur of the Snowdon range of hills in Carnarvonshire, informed me that a shelter plantation which had been formed some years previously along the exposed boundary of a portion of his farm was valuable to both man and beast. But this is by no means an exceptional instance, as on the Gwydyr estate, at Llanrwst, the agent pointed out to me two farms at high altitudes that had increased in rent value after tree planting had been carried out; a case that is common enough in the north of Scotland, and of which I have records.

Few, other than those who have been actually engaged at the work, have the remotest idea of the difficulties and hardships that are connected with the planting of exposed hill sides during the winter and early spring, especially such as are fully exposed to the prevailing wind of the district. The fierce, long-continued and hard-hitting blasts, that are almost constantly experienced on the Scottish and Welsh hills and other exposed grounds, tell hardly on newly-planted trees, be they of whatever kind, and point out that a great amount of discrimination is required in dealing with such situations.

Previous to forming the plantation first referred to, which was at altitudes up to fully 600 feet, and fully exposed to the almost incessant winds that blow from the Atlantic Ocean, the adjoining lands were quite incapable of cultivation, but now crops have gradually crept up the hill-sides, while the farm stock find a much needed shelter that they were formerly denied. The benefit to both crops and stock was particularly marked, as previously where only the hardy mountain sheep could exist, cattle of several kinds are now to be seen, while Corn and Potatos occupy much of the land that was formerly growing Heath and Gorse. The belt of plantation referred to, which was long and narrow, bounded the entire length of the higher-lying lands of the farm, and was in one continuous piece, with indentations for the sheltering of sheep and cattle during inclement weather.

Previous to preparations for planting, the land was tenanted by such dwarf, shrubby growth as the dwarf Willow, Juniper, Gorse, and Broom, the last, on the drier portions of the ground, while in dampish hollows the Alder and Thorn were conspicuous by their procumbent habit of growth.

The land to be planted was first enclosed by an iron and wire fence, except on the higher side, which was bounded by a stone dyke and ditch. Clearance of the land from all rough-growing vegetation that would be likely to interfere with planting was next engaged in, while a few ditches were opened where necessary, and the pits for the trees dug at distances which varied from three feet to four feet, according to exposure. The soil being of a free, loamy character, the cost of opening the pits, which was carried out by the unemployed at a cheap rate per hundred, was not excessive, while plants were obtained at the time on very moderate terms, a small proportion being from a nursery on the estate. The preparatory work was carried out during the autumn and winter, the planting of the trees being deferred until the early spring. The trees included the Common Larch, Scotch and Corsican Pines, Sitka Spruce, with a few of the common species in the lower grounds, and in the damper hollows hardwooded trees, such as the Alder, Willow and Poplar were planted. Douglas Fir was tried but proved a failure owing to the wind-swept nature of the position. Along the most exposed parts the Austrian and Corsican Pines did unusually well, these being good trees for such positions. Altogether the trees have thriven well, and impart a great amount of shelter to the exposed lands adjoining.

Around many of the high-lying farmyards and fields both in England and Scotland, the common Spruce is largely employed for shelter and around many of the Hop gardens in Kent and elsewhere, the fast-growing Poplar, Willow and other trees of an upright growth are made use of, in order to protect the tender foliage and crop from cold winds, without which it has been found impossible in certain districts to cultivate this plant successfully. There is no necessity to plant extensive woods, long and narrow belts, if judiciously arranged and planted, being equally as effective as denser masses of trees. Often a clump of the right kind of trees if properly placed, will afford a great amount of shelter both to cattle and buildings. For these purposes the evergreen Oak is a most valuable tree, which thrives as well on the sea shore as inland, and is capable of withstanding a large amount of rough usage from cold winds and full exposure. Clumps of the common Scotch Pine, as also the Austrian and Corsican Pines, are also well-adapted for similar sites, and afford a large share of protection to houses and farm stock generally.

Great care is necessary in the management of such trees, in the matter of giving the individual specimens plenty of room for the perfect development of both root and branch, so that a firm root-hold may be secured and the branches retained in a healthy condition, on which wholly depends their value for the purpose under consideration. When allowed to press on each other, the lower branches soon give way, thus counteracting the very purpose for which they were intended. *A. D. Webster.*

GARDEN TOOLS.

THE word "tool" has a very wide application, but in this article it will be necessary to limit its meaning to "any artificial implement, machine or mechanical contrivance used to assist, facilitate or increase the faculty of human expression in any matter relating to art, science, manufacture or industry!"

It will also be necessary to deal mainly with the tools concerning our own particular industry, but it will not be necessary to make this compartment too watertight. If digression is criticised, I would remind critics that the great enemy of progress in the past has been narrowness of outlook, with a tendency to assert, for our own particular sphere, a knowledge so specialised and complete as to give us the right to pose as experts. In truth the "expert" is too often the most fatal bar to progress.

Einstein's theory of "relativity" suggests the correlation of all fundamental scientific principles in aid of one great advance in the interests of mankind, and although this may seem remote from "garden tools," in reality it is not so. What I am now pleading for is the receptive mind, a faculty for assimilating and benefiting by the result of scientific research, an enquiring attitude towards any and every article or action with which we come in contact.

Can this be applied to such a common, everyday article as, for example, the garden hoe? I hope to show that it can, and the questions I would suggest are:—(1) Why do we use this particular tool, and how far could its use be extended or curtailed? (2) Is it the best that can be provided for the particular purpose required, or could it be improved to give greater results with an economy of effort? In this connection we might enquire whether the construction is based on scientific principles, and whether similar objects in other spheres of industry are achieved by the use of superior appliances which might with advantage be copied in whole or in part.

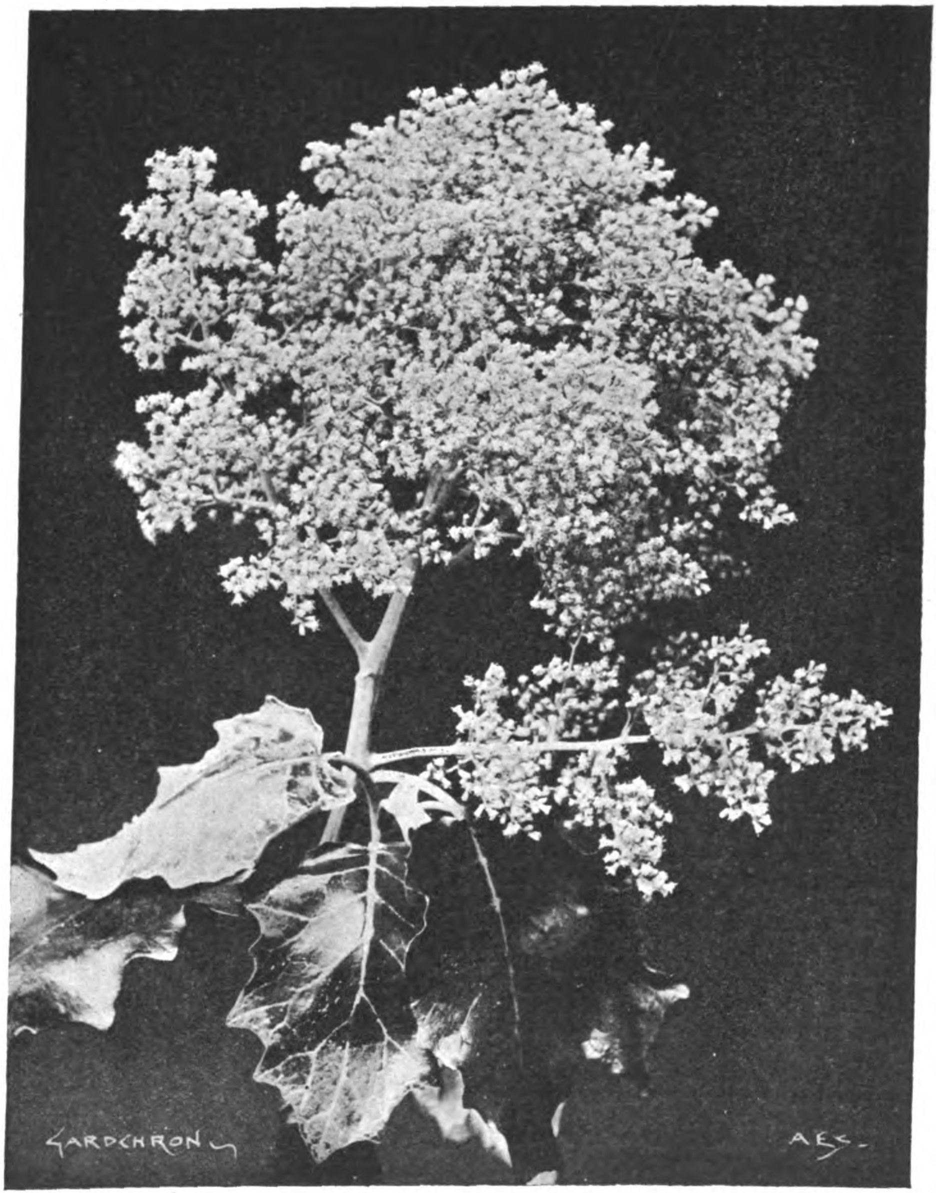

FIG. 9.—BRACHYGLOTTIS REPANDA (INFLORESCENCE).
(see p. 14).

Could time and space be spared, it would be highly instructive to trace the history of tools from the earliest times. As G. K. Chesterton might observe, the use of tools is not an essential or natural characteristic of the human race; that is to say, they are not provided at birth. Animals, other than human beings, get on very well without them, and the remains found in the geological strata of early periods provide no indication that our prehistoric ancestors found them necessary to life. They are thus a product of civilisation. It is not surprising to find that the first indications of the provision of tools by prehistoric man relate to weapons of war. The contrast between the crude, flint arrow heads and the modern weapons of destruction may be quoted, ironically or otherwise, as an example of the onward march of civilisation. Strangely enough, when we come to agricultural tools, we do not find evidence of equivalent progress.

This gives food for thought. Now that, as we all hope, the sword had been definitely turned for all time into the ploughshare, is it not time to use some of the ingenuity and inventiveness formerly directed to the organisation of war to improved methods of increasing the production of the fruits of the earth? In this connection, too, we may well ask whether agriculture, including horticulture, is doomed always to be the Cinderella of the industries.

Horticulturists must be ready and willing to work out their own salvation. They must also be watchful for, and ready to profit by, the existing advantages of civilisation. I refer not only to the research conducted by government departments and various private bodies, and recorded in their official papers, but to the countless advertisements of all kinds of labour-saving contrivances and conveniences which may be found in the advertising columns of any paper. In most cases these appliances save in labour many times their cost. As a nation, we are essentially conservative and slow to adopt new methods, and this applies particularly to gardeners.

I commence with the spade, because from time immemorial it has been quoted as typical of the gardener. When this apparently simple article is considered in detail it will be realised how we approach a problem in a truly scientific manner. For example, the following points will arise in connection with the spade: (1) The length of the blade; (2) its width; (3) shape of the penetrating portion; (4) curve or flatness; (5) thickness of the metal; (6) weight; (7) material; (8) sharpness of the blade; (9) surface; (10) the use of lubricants to facilitate smooth action of the blade; (11) the method of affixing the blade; (12) the length and slope of the handle: (13) the special arrangements for grasping the handle. Again, in the connection with the method of use the following points arise:—(1) the size of the spit: (2) the angle of striking the soil; (3) the height of raising the spade for striking; and (4) the method of leverage.

Many other points will occur to readers, but what I wish to make clear is that there must be a "best method" for each of these points, or rather, a series of "bests," applicable to the heights, weights and energies of the operators and to various soils and conditions. This "best" may be defined as the ideal spade, the use of which would enable a given area to be dug to a required depth under average conditions by the exertion of a minimum number of foot-pounds of energy. If the ideal has been realised its realisation has been fortuitous and the period over which it operated fragmentary. But every foot-pound exerted above the ideal minimum represents so much waste of energy, a waste that might be avoided. Enough has been stated to show that in the thousands of gardens in this country we may waste enough energy every year to turn the waste lands of Britain into smiling gardens, growing enough to provide all our needs in the shape of food. We see columns written in the sporting Press about the swerve of cricket balls, the exact angle at which to hold the bat, etc., etc. Machines have even been brought into action for recording the exact speed of a cricket ball delivered by a fast bowler. But as yet we have not taken steps to find out in respect of the simplest garden tools the precise methods of structure and use that would give the greatest efficiency. I hope the relevance of my apparently irrelevant observations concerning Einstein will now be apparent. The gardener, as such, cannot settle the problems of tools himself. He must seek the aid of many men of science, the help of the professor of statics and dynamics, the metallurgist, the chemist, the geologist, the physiologist, even the psychologist. The gardener would be too much inclined to "call a spade a spade" and think he had settled the matter.

Awaiting the advent of ideal tools, the possession of the best available is a very important item of garden economy, and money spent on them is an excellent investment. A good tool facilitates the work of a competent man and robs the incompetent of a handy excuse. *W. Auton.*

(*To be continued*).

EARLY FRUITION.

THE astounding output of Dr. van Mons in new varieties of fruits, especially Pears, so many of which are still held to be of sterling merit, must have been due to some successful technique, though what that technique may have been is not within my knowledge. An early knowledge of the quality of the fruit of a seedling must obviously be a very great help. Recently (*Gard. Chron.*, Aug. 29, 1925, p. 161), an article appeared, taking as its text a contribution by Mr. G. T. Spinks (*Journ. of Pomol. and Hort. Sci.*, vol. IV., 1925, p. 141); on reference to the original, it appears that beyond a sort of half-way confirmation of the continental adage "Winter pruning for Wood, Summer pruning for Fruit," root pruning and ringing seem to have been the only active endeavour to promote the desired object; it is expressly stated that no summer pruning was done, and that the quest was abandoned. Examination of past literature reveals quite a number of procedures that have been entertained in order to accelerate fructification; some of which might well be tried in any organised attempt to get early knowledge of the value of a given seedling.

First may be mentioned the grafting and re-grafting of a seedling upon itself, which I think has been repeated three or more times; possibly this was one of van Mons' methods. It would seem to be applicable to very strong growers to check their immediate vigour. Next, there is the question of utilising "stipulary" buds; already in 1857, du Breuil (*Instruction élémentaire sur la conduite des arbres fruitiers*, Paris, 1857) had remarked on the remarkable fruitfulness of the productions evoked from these latent eyes, so that the knowledge must date still further back. In more recent years the technique has been further evolved by Lorette, who actually formed whole trunks or main branches from shoots derived from "stipulary" eyes. I am not aware whether the method has been widely used on actual seedlings on their own roots; my solitary experience is with a Plum seedling, which, however, did not blossom till the ninth year from sowing; it was, however, only "stipularised" once. If repeated, "stipularisation" might be somewhat comparable to repeated "on self" grafting. A number of modes have been described to bring these latent eyes into growth.

Then there is the comparatively simple procedure of bending—for instance, turning an upward-growing scion or shoot into a horizontal, (or slightly upward or downward) cordon—for a horizontal or depressed direction often leads to an early production of fruit spurs, whilst remaining upward growths continue infertile. Twisting, or twisting combined with bending, is another practice which may be mentioned.

Next, besides the classic summer pruning, in which a cutting instrument is employed, we have the "pinchings" (*pincement*) done in the green with finger and thumb, about which there has recently been so much discussion on the other side of the Channel. Somewhat allied, we have "breakage" (*cassement*), which may either be complete, leaving a ragged end, or partial—the green-stick fracture of the surgeon—in which a certain portion of the sap is able to pass to the tip, but the active flow, which would cause woody growth, is checked; the instruction usually given is to do the breaking over the back of a knife or some other hard edge. The Lorette system of developing basal latent buds, other than stipulary ones, may also be noticed.

In practice it would appear that two opposed principles may be the objects of concern (1) to promote, (2) to repress vigour; especially perhaps when dealing with seedlings. From observations, it would appear we may successfully strive to achieve either with material obtained from older trees, and inferentially the same may be possible with young seedlings. Thus, in regard to repression, an old cordon (Pitmaston Duchess), some twenty feet high on a wall, has been made a sort of museum at its lower part; some five sorts have been grafted on lower branches, and though, in some cases, others of the same lot of grafts have grown actively and normally, when given normal conditions, on the rather sapless situation of the old cordon they have consistently done nothing but make fruit buds and bear fruit without shoot formation. Next spring, I think of putting on some seedlings, and it may be noted that on such a subject there is a possibility of selecting varying degrees of sappiness at different heights.

In regard to promotion of growth, though not strictly scientifically controlled, as the intermediary stocks were not identical in nature, the following may be cited: grafts of Thompson's Pear were put on cut-back, youngish trees on Quince stocks, one set on Passe Colmar against a wall, the other on Citron des Carmes in the open: the former made nearly four times the growth of the latter. I recently recounted (August, 1925, p. 134) the vigorous growth obtained from a bud of a small-growing old, perry-Pear tree when inserted in a vigorous stock against a wall. This year a very striking contrast is afforded between grafts of a Serbian Quince placed on a cut-back Quince stock against a wall and one of the same lot of grafts placed high up on a branch of a forty-year-old all-spurred standard Pear (the grafting of Quince on Pear dates back some centuries). The former in its luscious and warmer site has made a growth of six feet, with a basal diameter of half-an-inch and the lower leaves measured six-and-a-half inches by five inches, whilst the latter on the old Pear tree have made spindly growths of six inches and seven-and-a-half inches only. Which of the two will first blossom and fruit remains for the future to tell, but the lesson seems fairly obvious that when we desire to promote growth the procedure to be adopted is to graft on a vigorous and sympathetic stock in a warm and sheltered situation. It may well be in the case of seedlings that advantage would accrue, if, first, a growth-promoting graft were made and from the resulting shoot a second grafting followed in a repressing situation, though here, too, the shelter of a wall may not be disadvantageous. At the same time the vigorous scion may be made to serve for trial of other repressive measures such as "stipularisation," or varied summer treatments.

Height above ground is also a possible factor in fruit bud development in some cases. Thus I have noted that three cordon Quinces, on a wall (or *en espalier* as the French term it), some fourteen feet in height and of different varieties, all failed to produce any blossom below the five-foot level, and consequently I eventually cleared the lower parts, leaving a plain stem.

The effect of wall protection, which probably means matters of temperature, has already been given attention: two young Plum trees on the same stock and budded at the same time (Angelina Burdett) afford further evidence; one, left in the open, has blossomed three seasons and has not grown more than five feet in height, the other, placed against a wall, is over ten feet after pruning the tops, and has not yet borne a blossom. The former is in the neighbourhood of other Plum trees and nearly overshadowed by a huge Jefferson, which may have had some dwarfing effect and hastened blossoming; it may be that a reasonable amount of "overcrowding" might take a place in the programme.

Root pruning will hardly come to mind until excessive vigour of growth is present,

Of ringing, I have written nothing—our French friends generally merely mention it to decry it—and I have no personal experience with it beyond seeing a plantation which had been severely handled by vigorous ringing and much of which was grubbed later; but the object of getting early fruiting in a seedling is a different proposition to vandalising an orchard.

Manuring too must be mentioned, but here the need is to know in what form the two important elements—phosphorus and potassium—should be presented in order to favour the desired object; as also the effect of accessory agents, such as manganese and cerium (the latter has been said to have a marked effect upon Maize) and modifications of the soil bacterial flora. *H. E. Durham.*

BROWN ROT AND WITHER TIP OF PLUMS.

(MONILIA CINEREA, FORMA PRUNI.)

THIS disease causes a good deal of trouble in most gardens where Plums are grown as bush or standard trees. It does not generally cause any trouble on trained trees planted on a wall or fence. I am inclined to think that this is because summer pruning is more largely, and also more easily, practised on the trained trees.

Wither tip and brown rot of Plums is reproduced each season by spores from at least two sources. (1) Spores produced from the diseased wood—the wither tip form. (2) Spores produced from the mummified Plums which have been left on, or under, the trees—the brown rot form. Where summer pruning is carried out on trained trees, the main part of the first source is removed each season, also it is fairly easy to see and remove any mummified Plums that are present on trees of the trained types at any season of the year. Spraying up to the present has given very little control over this disease, and our main method of attack is the removal of diseased tissue each season, before this tissue begins to produce spores, *i.e.*, in autumn. This can be done on trained trees more easily and more thoroughly, and this fact seems to explain why the disease does not make headway on this type of tree.

In spite of all that has been written and said about this disease, many growers do not seem to be fully alive to the damage it does each year, or, if the damage is realised, little is done to control the disease. I visited an orchard recently where wither tip and brown rot were bad, especially on the variety Victoria. The grower told me his Plums had "missed" a crop this season, but I noticed that most of his trees were still carrying a fair crop of mummified fruits left over from 1924. At the time of my visit to this orchard, almost all the growths of 1925 were bent over with the characteristic curve which denotes this particular disease.

Lack of time and cost of labour are often given as reasons for not carrying out proper control measures for this disease, but, surely, if it pays to grow Plums at all, it pays to keep the trees healthy and capable of bearing good crops. Much of the work that is done in the control of the disease is carried out during the winter months, and while admitting that it is often more convenient to do the work at this time of the year, it certainly is not the best period. The best time to cut out dead and diseased wood from a Plum tree is during early autumn, for two reasons. In the first place the material to be cut away is more easily seen in trees that are in leaf; and secondly, the diseased material should be cut well back into sound tissue; if this is done during autumn, the wounds so made heal up before winter comes, but if the pruning is delayed until winter the wounds remain open all through the winter months. Wounds of this type give a free entrance to all sorts of fungous wound parasites, especially silver-leaf (Stereum purpureum).

If time could be spared for the removal of diseased tissue during September, I am sure it would make for better control. The earlier the work could be done in that month the better, because I have seen Stereum purpureum producing spores early in October in certain seasons, and it is certainly advisable to have all pruning wounds healed over before these spores appear, and while it is easy to paint over large wounds with some material which will stop the entry of spores, it is not practical to paint small wounds and fungous spores can just as easily get into plant tissue through a small wound as through a large one. *Somerset.*

HARDY FRUIT GARDEN.

MULCHING SMALL FRUIT QUARTERS WITH LEAVES.

DURING the dry period of the past summer many gardeners were concerned about the poorness of the Strawberry crop, and in many instances complete failure was experienced, especially on light soils.

It is almost hopeless to try and keep the beds moist by watering, as the water disappears as fast as it is poured on and the plants derive little benefit unless the ground receives a good mulching. There is no material that keeps the soil moist so well as a good mulching of ordinary tree leaves gathered from the pleasure grounds and woods. I place the leaves between the rows to a depth of six inches, and on this a light covering of long, straw-litter manure from the stables, or Bracken from the woods, to prevent the leaves from being blown away. The rows are examined occasionally for the purpose of preventing any plants from becoming covered. The leaves soon settle down, forming a nice bed, and there is no trouble from weeds. Strawberry beds treated in this way last summer gave excellent crops of fruit, without receiving any water; the leaves were put on in January.

New Strawberry beds, planted in September, 1924, which received a liberal dressing of bone-meal, and were well mulched with leaves, gave a wonderful crop of fruit in 1925.

Where labour is scarce, it is a good plan to cover all the squares of bush fruits—Gooseberries, Black Currants and Raspberries, after pruning; the leaves are wheeled in from the pleasure grounds and placed thickly all over the soil. It is wonderful how these fruits respond to a liberal mulching; and, again, there is no trouble with weeds.

Big bud on Black Currants needs close attention. After the fruits are gathered, and this should be so soon as they are coloured, while the buds are small, the bushes should be given a good spraying with a strong insecticide twice in one week. Bushes that were badly infested with big bud were treated in this way two years ago and gave good results; there was but one third of the amount of big bud as previously, and the bushes have carried good crops of fruit. They were sprayed with ten per cent carbolic soft soap, two ounces to the gallon of water; if some stronger insecticide were used still better results may have been obtained. *D. D. Robertson, Mount Clare Gardens, Roehampton.*

VEGETABLE GARDEN.

SCORZONERA, VIPER'S GRASS OR BLACK SALSIFY.

SCORZONERA HISPANICA, LINN.

THE Scorzonera is a very useful perennial vegetable, native to Europe. It is somewhat akin to Salsify, which it resembles in many respects, except its broader leaf and the colour of its skin, and by which it is rather overshadowed, although its uses as an esculent vegetable are quite equal to those of its pale-skinned brother. In one respect it is superior to Salsify, in that while Salsify deteriorates in fitness for use and quality of flesh after the plant has sent up its flower stems, Scorzonera on the contrary, retains its good qualities while increasing in size; its leaves are also naturally more numerous, and in their young state, make excellent salad.

According to Miller, "the name Scorzonera is derived from the Catalonian word Escorso, signifying a viper, because it is said to be of great efficacy against the bite of vipers. Authors write that the Herb being applied, takes away the venom from the bite of vipers. They say that if a viper be touched with this juice it languishes; and that a man may touch a viper safely if his hand be dipped in juice of this plant." Miller quotes eight different varieties, the first named being Scorzonera latifolia sinuata. Of this he states that it is "the sort commonly cultivated in English gardens for food and physick. This grows naturally in Spain. The root of the plant is Carrot-shaped, about the thickness of a finger, and covered with a dark brown skin. It is white within and has a milky juice. This is the only variety cultivated for use, the others are preserved in Botanic gardens for variety."

Dodoens quotes only one variety, the Adder Herb. Its name in Spanish being *Scurzonera*; in Latin it is *Viperina*. Respecting its virtues he tells us, "It is thought to be marvellous good against the bitings of vipers, snakes and other venomous beasts. It has yellow flowers, and leaves broader than Salsify. It is found in Hungary, Thuringia and Bohemia, and a rose-coloured variety in Italy (so men say) known as Viperaca Italica."

Gerard's *Herbal*, 1697, names two varieties only: "Spanish, narrow-leaved. Hungarian, broad-leaved," and states that the uses are the same as Salsify.

As regards the present day position of Scorzonera, very little has been done to add new or improved varieties to the very limited list. The following are the most useful; Giant Russian: roots long, very smooth and tender, and of excellent flavour. Very popular in France. Vulcan: a German variety, having thick, roots, with pure white flesh. Improved Annual Giant: a Dutch variety of which the raisers state that "sown in spring it gives in autumn fine large, smooth roots, without running to seed like other sorts." If this variety is constant, it should be a desirable acquisition.

In addition to the Spanish Scorzonera, there is a variety named French Scorzonera; Scorzonera picroides, Linn., of which the young leaves are cut and used as green salad. The plant is an annual, but after being cut it sends out fresh leaves, and several successive cuttings may be made in the course of the season; see *The Vegetable Garden* of Vilmorin. *S. B. Dicks.*

HOME CORRESPONDENCE.

Late Wasps' Nests.—My thanks to Mr. Harrison who has kindly sent me portions of one of the nests and some of the wasps referred to on p. 432. I am now able to state that they belong to the species known as the Small Common Wasp (Vespa vulgaris), which more often makes its nest in hollow trees and logs than its very close relative the equally common Large Common Wasp (V. germanica), the latter, in my experience, rarely nesting anywhere but in the ground. The "paper" of the nest V. vulgaris makes is almost invariably some shade of brown, as this species uses rotten wood, whereas that of V. germanica is equally invariably some shade of grey, because sound (though dead) wood is used. I have found V. germanica much commoner in 1925 about here than V. vulgaris, as I have met with only three nests of the latter and about thirty of the former. I have also seen or heard of three nests of the hornet (V. crabro) here—a most unusual thing—two being in Oak trees and the other under the tarpaulin on a haystack in a farmyard. All were small. Even in 1921, the last "wasp year," I heard nothing of hornet's nests about here. *C. Nicholson, Hale End, Chingford, Essex.*

SOCIETIES.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

Mr. J. R. Butler presided at the monthly meeting of this Society, held in the R.H.S. Hall, on Monday, December 14.

Eight new members were elected. Three members withdrew interest amounting to £7 7s. 2d., and two members over the age of seventy years withdrew the sum of £7 10s. 0d. from their deposit accounts. The sum of £106 1s. 4d. was passed for payment to the nominees of two deceased members. The sick pay for the month on the ordinary side came to £81 5s. 2d., and on the State section to £83 19s. 8d.; maternity claims totalled £10. Grants were made to twelve members for dental, optical and surgical treatment which amounted altogether to £62 2s. 5d.; eight other cases were considered.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

Friday, December 4.—*Committee present:* R. Ashworth, Esq. (in the chair), Messrs. A. Burns, A. Coningsby, J. Cypher, J. Evans, E. W. Thompson, and H. Arthur (Secretary).

First-Class Certificates.

Odontioda Seymouriae var. Lilacina.—A well-shaped flower, nearly three inches across, of lilac-pink colour, the broad lip being a dark shade. From Mrs. P. Smith.

Cypripedium Bulldog (*Shogun* × *Dreadnought*).—A home-raised seedling. The flat, dorsal sepal has a white margin, and the base is beautifully spotted; the broad sepals and lip are a rich brown. From R. Ashworth, Esq.

Cypripedium Minotaur var. compacta (*nitens Leeanum Bectoniae* × *Euryades var. Rex.*).—This variety has a large, round, dorsal sepal measuring over three inches across, white, with a green base, delicately spotted. From Capt. W. Horridge.

Award of Merit.

Cypripedium Boleus (*Actaeus*) *Ashlands variety* × *Bottonii*).—From Mrs. P. Smith.

Thursday, December 17. — *Committee present:*—A. Hanmer, Esq. (in the chair), Messrs. R. Ashworth, C. Branch, A. Burns, A. Coningsby, D. A. Cowan, J. Cypher, J. Evans, G. Giles, A. Keeling, D. Losh Thorpe, J. Lupton, E. W. Thompson, and H. Arthur (Secretary).

First-Class Certificates.

Brasso-Cattleya The Baroness var. Margaret.—A fine-shaped flower of rich yellow throughout, with the exception of the throat, which is lined with red. From J. B. Adamson, Esq.

Cypripedium Columbus (*Christopher var. Grand Duke Nicholas* × *nitens Leeanum variety Hannibal*).—An exceptionally large flower; the dorsal sepal is very broad, the ground colour being green, and freely spotted with rich brown, with a white margin.

Cypripedium T. B. Armstrong (*Euryades* × *Draco*).—A well-shaped flower, the dorsal sepal being spotted with reddish-brown. Both from S. Gratrix, Esq.

Odontioda Dacia var. Solario (*Odm. eximium* × *Odta. Charlesworthii*).—The flower is solid madder red in colour; the large flat lip has a white column. From Sir J. Rutherford, Bt.

Awards of Merit.

Odontoglossum Thoro (*Prince Albert* × *crispum, blotched variety*), and *Cypripedium Eurybiades Edgemoor variety.* From A. Hanmer, Esq.

Cypripedium Nabob II (*Gaston Bultel* × *Charltonii*).—From Mrs. Gratrix.

Cypripedium Garland var. compactum (*Lord Wolmer* × *Euryades New Hall Hey*).—From Mrs. P. Smith.

Laelio-Cattleya Schröderae var. Queen Alexandra.—From J. B. Adamson, Esq.

Groups.

A Gold Medal was awarded to J. B. Adamson, Esq., Blackpool (gr. Mr. R. Taylor), for a group of Orchids.

S. Gratrix, Esq., West Point (gr. Mr. C. Branch), was also awarded a Gold Medal for a fine group of Cypripediums.

Silver-Gilt Medals were awarded to A. Hanmer Esq., Buxton (gr. Mr. G. Giles) and Mrs. Bruce and Miss Wrigley, Bury (gr. Mr. A. Burns), for groups of Orchids.

Messrs. J. Cypher and Sons, Cheltenham, staged a group for which a Silver Medal was awarded.

ANSWERS TO CORRESPONDENTS.

Correct Labelling of Batches of Plants.—*A.* The correct method of labelling plants, whether these be species or varieties, placed in nursery lines or in pots on a greenhouse bench, is to place the label immediately behind the first plant (or in the first pot) in the first row. Continue the rows from left to right, and always commence each row from the front, otherwise mistakes are liable to be made when one variety ends and another begins part of the way along a row—unless, of course, the varieties are distinguishable at sight.

Flowers, Vegetables and Tomatos.—*Problem.* (1) A flower border can be kept in a fertile condition for a longer period without manuring than a vegetable garden, provided that both are put in a proper condition for their respective crops by trenching and manuring them before planting or sowing the same. The majority of flowers prefer a soil that is rather open by having a greater percentage of sand in it, than would be best for vegetables. Potatos are an exception, and prefer a soil that is inclined to be rich and sandy rather than of a clayey nature, so far as quality is concerned. Stems of perennial flowers should be allowed to ripen before they are cut down. By that time all the starch in excess of requirements for the production of flowers has passed down to the roots and is available to give the plants a good start in spring. All good gardeners cut off the fruiting portion of the stems so soon as the flowers are over, and thus prevent a great drain on the plants and on the soil for phosphates, potash and nitrogen required for the production of seeds. Instances are Sweet Peas, Antirrhinums, Delphiniums and other plants that produce a great quantity of seeds. Vegetables, on the other hand, require a great deal of manure every year to build up their vegetative parts, such as Cabbages, Brussels Sprouts, Cauliflowers, Leeks, Onions, Celery, etc. All these are harvested and removed from off the ground. They require a great deal of nitrogen to stimulate growth. Peas and Beans of all kinds leave the ground richer in nitrogen than it was before, but appropriate a great deal of phosphates and potash in their seeds, greater, indeed, than the soil can supply to support the heavy crops expected. If a second crop were taken off the same soil without manure, this crop would be poorer than the previous one. An inadequate rainfall must not be confused with a lack of fertility. Artificial manures are next to useless in the absence of rain or artificial watering, because moisture is necessary to carry food into the plants. A deep root-run and plenty of farmyard manure will help vegetables to endure a drought because of the moisture held by the manure, rather than the little food in it. A flower border may continue to give satisfaction for quite a number of years without manure, if properly cultivated. (2) Tomatos are, or should be, always grown in warm, sunny positions. At the end of a warm day, during a drought especially, like that of last June and July, the leaves and tips af the shoots may be seen to flag considerably. All parts of the plant were then more or less limp. The result was that the plants threw off the flowers at the joint below their stalks. Apples, Pears and Plums behave in the same way by casting the larger proportion of their fruits after they get to some size. The pollen of Tomatos is not wetted by spraying, because the flowers hang downwards, and the pollen has to fall out of the tips of the anthers by a small pore before it can be wetted. Spraying the plant stops transpiration, and the rising sap fills the cells with water and gives the whole plant its normal rigidity, and the flowers hang on.

Names of Fruit.—*E. N. B.* 1, French Crab; 2, Dumelow's Seedling; 3, Margil; *G. S.* Jolly Beggar. *Osmond.* 1, Court Pendû Plat; 2, New Bess Pool; 3, Gilliflower. *G. A. L.* Radford Beauty. *P. H. R.* 1, Peasgood's Nonesuch; 2, Trumpington. *G. H. F.* 1, Wadhurst Pippin; 2, Hormead Pearmain; 3, Bramley's Seedling; 4, Ross Nonpareil; 5, Broad-eyed Pippin. *C. W. S. G.* Vicar of Beighton. *C. R.* 1, Lane's Prince Albert; 2, Cox's Pomona; 3, Lord Burghley; Pear Beurré Diel.

Names of Plants.—*E. N. B.* Polypodium aureum.

Pelargonium Seedling. *R. F. B.* The flowers of your Pelargonium seedling are very bright and attractive, but we doubt whether the variety differs greatly from some already in commerce. In any case, it is difficult to determine a Pelargonium at this season of the year. We suggest that in due course you send flowers to one of the Pelargonium specialists. The Begonia appears to be a variety of B. semperflorens.

Rabbits and Lily-of-the-Valley. *Frognal.* Our experience with rabbits in a garden, where the neighbourhood or surroundings were infested with them was that they were troublesome in winter, when food was scarce, but that would not apply to Lily-of-the-Valley, which dies down in autumn. In spring there were Snowdrops, Daffodils, Corydalis and Doronicum Pardalianches, but these bloomed without molestation. The rabbits were most fond of Carnations, Pinks, Violas and Pansies. When there was plenty of grass, Dandelions and Clover, the rabbits did no damage in spring and summer, except in one case, where the flower garden was not fenced against rabbits. The young ones gnawed the stems of Zonal Pelargoniums and left them lying scattered about. During periods when snow covered the ground, rabbits would eat off the tops of young Spruce trees, and the bark of Beech and Laburnum, of which they are fond. Seeing that snow is seldom present in quantity in your district there would be little incentive for the rabbits to be mischievous in winter, and less in spring, when Lily-of-the-Valley commences to grow. If there is not much grass in spring in the wood it would be worth while planting some Cabbages or Kale to engage the attention of the rabbits until grass is plentiful.

REMARKS.—The supplies generally were fairly plentiful at Christmas, and the only subjects that advanced greatly in price were Carnations and Roses. These reached their highest value on Tuesday and Wednesday last, possibly owing to the increased demand from the provinces. Richardias (Arum), although in moderate demand, remained firm in price. Lilium longiflorum declined in value before the market closed on Christmas Eve, the supplies exceeding the demand. Tulips and Hyacinths on bulbs met with a ready demand from the previous week. More cut Tulips were available last week, pink and yellow blooms being exceptionally fine. There was also a good display of Poinsettias. Daffodils and Christmas Roses were scarce and many orders for these blooms could not be accepted. Small consignments of Narcissus Soliel d'Or from Guernsey arrived in fine form, also some single Anemones, Violets and Smilax. On Thursday, Violets from home growers reached the highest figure this season. All supplies of cut blooms from France were very short and advanced considerably in price, especially for Anemone, Narcissus, single and double Violets, Ranunculus, Acacia (Mimosa), and Marguerites were unusually scarce, and the quality, generally, was poor, but prices were exceedingly high for this time of the year. Supplies from this quarter are likely to be limited for some days.

REMARKS.—The week following Christmas is usually quiet from a business point of view, and this one has been no exception. There was no great rush of trade during the Christmas week, but there was a steady volume of business all through, and results have no doubt been satisfactory. Ample stocks of Apples from the United States and Canada are on hand, and quotations for these fruits are inclined to be easier. The enquiry for English Apples just now is very quiet, and even Cox's Orange Pippin is not in demand. A week or so should see some slight improvement in this section. Hothouse Grapes continue to be in fair demand, the New Year festivities helping in this direction. Oranges are plentiful and cheaper. Bananas remain steady and their prices show little or no fluctuation. Forced vegetables are a fair trade, French Beans in particular being scarce and dear. Hothouse Potatos and Peas are, however, both cheaper. New Potatos from the Azores, Canary Islands and Algeria are in poor demand. Mushrooms, as is usual at this season of the year, show considerable variation in prices. Somewhat heavy supplies from Paris also help to complicate matters, from the home producer's point of view. Home-grown, forced Asparagus is meeting a poor enquiry, but French (Paris Green) is selling fairly well, the lack of colour being the detrimental factor of the English stems. A few Cucumbers are still coming to hand but they are dear. Tomatos, mainly from the Canary Islands, are not meeting a good reception by the buyers just now, but some improvement is looked for. French salads, such as Lettuces, Batavian Endive and Chicory from Belgium are all selling fairly well considering the large quantities that are arriving. Trade in old Potatos is fairly good, with ample stock on offer at steady price level.

GLASGOW.

A good business was done in the cut flower market during Christmas week, when good quality blooms were scarce and dear. Nearly all the local growers of Chrysanthemums have finished for the season and the trade is now dependent on English produce. Medium-sized blooms of Duckham made 4/- to 5/- per dozen; large 5/- to 6/-; Winter Cheer, 1/8 to 3/4; Niveus and Wilcox, 1/8 to 2/6; large, 2/6 to 3/-; Sunshine and Ada Brooker, 2/- to 3/-; and Heston White, 1/8 to 2/8. Roses were worth from 7/- to 10/- per dozen, and Carnations, from 7/- to 9/-. White Hyacinths made 10d. to 1/6. Lily-of-the-Valley 2/- to 2/6; English Violets, 3/-; Narcissi, 4/- to 6/- per dozen bunches; small French Ranunculus, 1/- to 1/6; Smilax, 1/6 to 2/-; and Asparagus Fern, small, 6d. to 1/-, large, 1/- to 1/6; Lilium longiflorum (Harrissii) and Arum Lilies ranged from 8/- to 10/- per bunch, and Lilium speciosum rubrum from 3/6 to 5/-. Blooms on bulbs were plentiful. Prices for White Hyacinths fluctuated between 2/- and 3/- each; Tulips, medium-sized, 1/9 to 2/6, and large, 3/- to 4/-. Solanums in pots averaged 1/3 each, and Dutch Aspidistra realised from 9d. to 1/- for green, and 1/- to 1/3 for variegated forms. Holly supplies were short of the demand, and buyers conceded 7/- per box, while Mistleto varied from 5/- to 6/- per stone.

The feature of the fruit market was the slump in the value of Oranges. Cases of 714's, which were quoted a week ago at 24/- to 28/-, dropped to 16/- to 19/-, while 420's only made 17/- to 24/-, as against 24/- to 35/-. Other counts were proportionately cheaper, 300's being 11/- to 14/-, compared with 14/6 to 20/-, and 360's, 9/6 to 11/-, against 12/- to 14/6. Murcia 360's were worth from 9/- to 10/6, and 300's 10/- to 14/-. Mandarin 50's 1/6; 55's, 1/8 to 1/10; 60's, 2/- to 2/3; Lemons, 300's 14/6 to 18/-. Jamaica Grape Fruit sold at 22/- to 24/6; Porto Rico, 25/- to 28/-; and Blue Goose, 30/-. There is still a good deal of wastage in Almeria Grapes, which were worth anything from 10/- to 26/- per barrel. Prices of American Apples generally displayed a downward tendency for case fruit, and the lower grades of barrels were also cheaper. Quotations were as follow:—Winesap, 12/6 to 16/- per case, Delicious, 11/6 to 16/6; Oregon Newtown 12/6 to 18/6; Spitzbergen, 11/- to 14/-; Jonathan, 10/6 to 14/-; Winter Banana, 12/- to 14/-; and Rome Beauty, 10/6 to 12/6. Canadian Kings, 28/- to 32/- per barrel; Spig. 24/- to 28/-; Greening, 28/- to 32/-; and Baldwin, 24/- to 28/-. English grown Bramley's Seedling realised 16/- to 20/- per cwt.; Lane's Prince Albert, 14/- to 18/-.

LAW NOTE.

DISPUTED SCOTCH SEED POTATO CONTRACT.

AN important decision, reversing the finding of the Lord Ordinary, was given by three judges of the First Division of the Court of Session, on Friday, in an action raised by Messrs. R. and S. Paton, Ltd., Potato merchants, 34, North Bridge, Edinburgh, against Robert Wyllie, farmer, The Heugh, North Berwick, in which the sum of £1,467 was claimed as damages for breach of contract. The pursuers, it was averred, purchased from the defender four hundred to five hundred tons of King Edward seed Potatos, and it was a condition of the sale that the Potatos were to be properly dressed, and any bad or wrong tubers kept out. It was the latter point that was in dispute. Relying on the contract, the pursuers sold the seed Potatos to various customers, who subsequently claimed damages on the ground that the Potatos were mixed and included a large proportion of tubers which were not true King Edward seed. In consequence, the pursuers had made reparation amounting to £1,000 to the sub-customers.

In the Outer House, Lord Ashmore decided in favour of the defender, and found him entitled to expenses. He was of opinion that the defender did not sell pure King Edward Potatos, and that he did not agree that in the process of dressing he would keep out the wrong ones, or rogues, as they were called. He also found that the representation made by the pursuer to his customers was done without the authority, expressed or implied, and without the knowledge of the defender.

A reclaiming note was presented to the higher court, and the three judges of the First Division have unanimously recalled the Lord Ordinary's interlocutor, and sent the case back for the purpose of dealing with the question of damages. Their lordships were of opinion that the contract was for the purchase of goods by description, and not for the purchase of mixed Potato seed

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 38.1.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, January, 6, 10 a.m. Bar. 30.0. Temp. 53°. Weather, Sunny.

Variety Trials and Tests.

EVERYONE who considers the great and continuous attention which is paid to the cropping values of new and old varieties of fruits and vegetables must be puzzled and baffled by the diversity of opinion which is prevalent with respect to the merits of the several varieties. Ask, for example, a dozen experienced growers what is the best or most profitable variety of Black Currant, Gooseberry, Apple or other fruit and there will be assuredly no unanimity in the answer. To anyone accustomed to the vagaries of living things this diversity of opinion will seem natural. Different varieties of one and the same kind of plant behave differently under diverse climatic and soil conditions. Some come earlier into bearing and some are more prone to disease, and again, some respond to pruning in one way and some in another. Therefore, in view of these and similar facts, the grower rightly enough comes to his own conclusion on the subject of suitable and profitable varieties and is inclined, also naturally enough, to adopt a cautiously conservative attitude with respect to that subject. This no doubt is well enough and there can be no question, but that on the whole the better varieties tend to survive in cultivation, as in Nature, and the poorer varieties tend to drop out of cultivation. But the numerous trials of varieties that have been made during the past ten years and more—at the various fruit stations, and at Wisley and elsewhere—all seem to indicate that if we only could know which varieties to grow on our land, our cropping results would be markedly improved. The indications which emerge from these trials however, whilst they whet our appetite for more precise knowledge, rarely succeed in supplying it. This defect is, let it be said, no reflection on the stations making the trials. The trials and the records are made, as we have often observed, with the greatest care and therefore the fact that no consensus of opinion exists with respect to the best varieties must be due to one or both of two things. Either the vagaries of vegetation already referred to are so great that no trials can be of any great value, or the trials themselves are imperfect. Since the former view can lead only to the conclusion that variety trials are of very limited value, we will ignore it and follow up the other suggestion, namely, that variety trials of fruits, and it may be of vegetables, are, as at present generally conducted, not calculated to yield conclusive results. Fortunately for the usefulness of this line of thought the results of variety trials recently made with respect to one kind of fruit, namely, Black Currants, have been subjected to a very searching analysis by the investigators who conducted the trials and, as a consequence, certain conclusions with respect to the ordering of variety trials which are of capital importance, both to growers and experimenters, have been reached. The variety trial to which we refer* was carried out at the East Malling Research Station. In the course of the trial, which at the time of publication of this report had been carried on for four years, certain results of definite importance to growers were established. The chief of these results is that of the varieties tried, French, Seabrook's, Boskoop, Goliath, and Baldwin, the last named variety proved itself to be far in advance of all the others with respect to yield and value of crop. This, however, important though it be, is not our immediate concern. What does concern us and all interested in the advancement of horticulture is the conclusion to which the East Malling investigators have come with respect to the all important subject of what constitutes a valid trial. Those who desire to study the argument in detail should refer to the original memoir. Here we can only indicate the value of the argument and the conclusion which is reached. When a limited number of each variety of Black Currant was tested it was discovered, by subjecting the cropping results to mathematical analysis, that observed differences of yield might or might not have a real significance. A distinctly larger yield on the part of one variety might mean that it is in fact a better cropper than one which gave a somewhat smaller yield and it might mean nothing of the kind. The problem therefore is to distinguish between results due to chance and those due to the natural thriftiness of the varieties. Here again mathematical analysis supplies a means of diagnosis. As the number of plants of each variety brought into the trial increases, the hazards of chance tend more and more to cancel out, just as you may toss a penny a few times and have a run of heads or tails; but as the number of experiments of this kind is increased the proportion of heads to tails approaches more and more nearly to unity. It therefore becomes the first duty of everyone engaged in a variety trial to ascertain what is the least number of specimens of each variety included in the trial which will suffice to make chance results negligible from a practical point of view. To eliminate chance altogether from taking a hand in the result is neither practicable nor necessary. For instance, as the authors show, to demonstrate a difference of one per cent between two varieties would necessitate the growing of over 5,000 specimens of each kind. But in practice no one cares about one per cent and so such a counsel of perfection need not be sought. A ten per cent difference of yield is, on the other hand, well worth any one's while. It means two hundredweights to the acre on a one ton crop. This measure of accuracy may be obtained if the number of bushes of each variety grown in the trial is 57. Where the number of varieties to be tested is not great, so many bushes as, say, 60 of each kind, although considerable, is by no means an unmanageable number. If that number of uniformly treated plants be used the experimenter is justified in attributing significance to results which differ by more than ten per cent, but not to smaller differences. If, on the other hand, he required to achieve a greater precision—say of five per cent—he needs must grow some 228 specimens of each variety. Here, then, are facts which, as we are convinced, will lead immediately to a beneficent revolution in the way of conducting horticultural variety trials. We have all been content to work with an arbitrary and generally limited number of plants—quite useless, and a waste of time as the events have proved. With the knowledge adduced by the East Malling investigators, all who engage in variety trials must, as their first duty when setting out the results, give the numbers of plants used and the significance to be attached to the results which are obtained experimentally. The Royal Horticultural Society, so long and so honourably known for its variety trials, will no doubt take the lead in drafting rules of guidance in such trials so that all who engage in that valuable work may know what should be the procedure that must be adopted if the results are to be of value or merely to "add to worthless numbers," "worthless numbers." In the case of vegetable trials—other than Potato trials, which are already conducted on a scientific basis—seedsmen and raisers of new varieties will doubtless take account of these methods of testing the validity of results and apply them in their routine work. So, again, no doubt, will the R.H.S. For although it is true that many other imponderable qualities have to be taken into account—quality, size, flavour, and the like—cropping yield can never be disregarded and to obtain a just measure of yield, a variety trial must be so conducted as to make negligible the distracting intermeddling of chance.

Trials at Wisley in 1926.—The Royal Horticultural Society invited entries for the following trials to be carried out during 1926, in the experimental gardens at Wisley, viz., Culinary Peas (mid-season varieties only), Kohl Rabi, Cabbages for spring sowing, Savoys, Celeriac, maincrop Potatos, Aubrietias, and the following annuals:—Calandrinia, Cosmea, Everlasting Flowers, Linum, Nemesia, Lavatera, Nigella, Nemophila, Portulaca, Sweet Sultan and Viscaria. Seeds, tubers and plants for these trials should be sent so as to reach Wisley by January 31, 1926. They should be addressed to The Director, R.H.S. Gardens, Wisley, Ripley, Surrey (Goods via Horley Station, Southern Railway), accompanied by an entry form (obtainable from the Director) and duly filled up.

---

* Black Currant Variety Trials: Reliability of Results. By R. G. Hatton, N. H. Grubb and R. C. Knight. *Journal of Pomology.* Vol. IV. Parts 3 and 4.

Malham Cove marred.—By the fall of some three hundred tons of rock the beautiful glen known as Malham Cove, near Settle, Yorkshire, has been greatly marred. The cove rises in sheer limestone cliff from which the River Aire, has its source in a cavern, and was the favourite haunt of John Ruskin and Charles Kingsley. The dislocation of the rock was due to the recent frost, a portion of the higher ledge of the cliff striking the lower ledge in falling and bounding thence on its way down the steep hillside, carrying trees with it in its course. The largest fragment of rock is said to weigh some one hundred tons.

Rhododendron Society's First Show.—Since the time, now long ago, when there used to be an annual (non-competitive) exhibition of Rhododendrons in the Royal Botanic Society's gardens, at Regent's Park, there has been no exhibition devoted exclusively to these handsome, flowering shrubs. Now, however, the cult of the Rhododendron has become fashionable and extensive, encouraged by the beauty and usefulness of garden varieties and certain species, and also by the introduction from China of an extraordinary number of species, many of which are still rare in cultivation or have not yet reached the flowering stage in this country. The desire to be the first to introduce or to flower a new species is quite understandable, and probably the honour of being the first to flower a new species of Rhododendron is not less than that attaching, say, to the first flowering of Odontoglossum crispum or Dendrobium nobile, and no doubt the possible attainment of such honour has had not a little to do with the recent and widely spreading cult of the genus, to the formation of the Rhododendron Society and so to the first Rhododendron show organised by that Society. The show will be held at the Royal Horticultural Society's Hall, Vincent Square, Westminster, on Tuesday, April 27, and a schedule of forty-eight classes has been provided. The two principal classes are for groups of Rhododendrons, one restricted to the trade, and the other to amateurs; then follow classes for twelve species, twelve hybrids, three species, three hybrids, the best species, the best hybrid, and for single trusses of R. Falconeri, R. Wightii, R. argenteum or grande, R. calophytum, R. lacteum, R. fictolacteum, R. Aucklandii or Griffithianum. R. arboreum (red), R. arboreum (any other colour), R. niveum, R. campanulatum, R. Fortunei, Houlstonii, or any form of decorum; R. Davidii, Fargesii, haematocheilum, orbiculare or oreodoxa; R. pachytrichum or strigillosum; R. campylocarpum, croceum or Wardii; R. Thomsonii; R. haematodes or sperabile; R. neriifolium, R. rubignosum, R. Augustinii, and R. chartophyllum, Davidsonianum or yunnanense. There are classes for Chinese or Himalayan alpine species; for hybrids from given species; for plants lifted from the open ground, or in pots; for hardy hybrids in commerce; and for both deciduous and evergreen shrubs or trees, in flower, suitable for growing with Rhododendrons. It occurs to us that the schedule lays so much emphasis on species that there is little opportunity for an amateur with a small garden, and who possesses only garden varieties, to compete; but, of course, this limitation may be due to design and the Hon. H. D. McLaren, Lionel de Rothschild, Esq., J. B. Stevenson, Esq., E. H. Wilding, Esq., and P. D. Williams, Esq., who constitute the Committee, may have felt that the R.H.S. Hall would not be large enough to hold all the exhibits unless such limitations were imposed. Given suitable weather the show should be one of exceptional interest and provide an excellent opportunity of inspecting the flowers of many choice and rare species of Rhododendron.

Sir John Bretland Farmer, F.R.S., D.Sc.—The inclusion of the name of Prof. Farmer in the list of New Year's Honours has given great pleasure in botanical and horticultural circles, for the new knight is as much esteemed for his charming personality as for the valuable scientific work he has accomplished during his busy life, much of which has had a direct bearing on horticulture. Moreover, he is a keen amateur gardener, especially interested in alpines, and was largely responsible for rescuing the old Chelsea Botanic Garden from the condition into which it had fallen and for placing it again in the important position it occupied so honourably and usefully in bygone years. His long association with the Imperial College of Science and Technology, South Kensington, as professor of Botany and Director of the Biological Laboratories, is well-known to most of our readers; and he has filled this position with a dignity and brilliance which has made his name honoured in scientific circles the world over; he has been a Governor of the college since its foundation in 1907. But his activities have extended to further fields. For five years he has served as a member of the Advisory Council to the Lord President of the Committee of the Privy Council on Scientific and Industrial Research, and during that time organised and was first chairman and director of the Forest Products Research Board. He has taken an active part in establishing a research station for the Imperial Cotton Growing Corporation, and in January, 1925, he visited the West Indies to report on an area for this station. The recommendations he made, in conjunction with Mr. Killby, were all adopted, and have led to the purchase and equipment of a site of sixty acres in Trinidad. Sir John has been a Governor of the Imperial College of Tropical Agriculture, Trinidad, from its inception, and he had much to do with the earliest stages of the organisation of that college. In addition, he has served on a number of committees appointed by the Secretary of State for the Colonies, including one appointed rather more than a year ago, under the chairmanship of the late Lord Milner, to report on the recruitment and training of officers in the agricultural services of the Colonies. He is a Governor of the Imperial Institute and also a Commissioner of the 1851 exhibition. The much-prized Royal Medal was awarded to Sir John Bretland Farmer on the recommendation of the Council of the Royal Society in 1919, and amongst his other honours is the degree of LL.D. (Hon.) conferred on him by the University of Edinburgh in 1922. An erstwhile Editor of *The Gardeners' Chronicle*, it is peculiarly appropriate that his portrait should appear on this occasion in the Journal with which he was once so intimately associated. Our readers will join with us in congratulating Professor Farmer on the receipt of so signal and well-merited an honour.

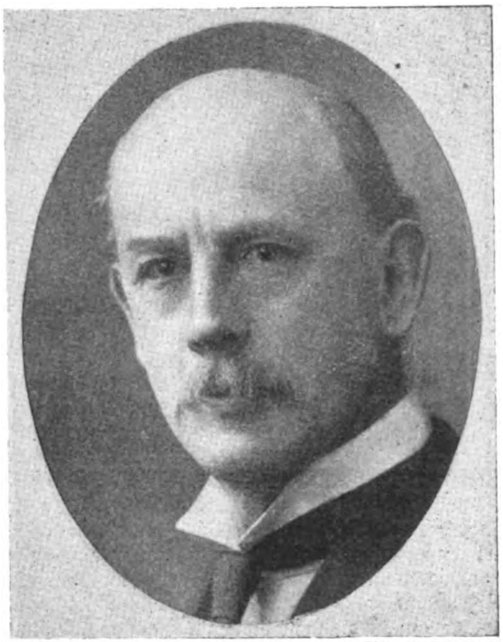

Photo by Lafayette.

SIR JOHN BRETLAND FARMER.

Webster's Foresters' Diary and Pocket Book.—This familiar red-covered diary is one of the most useful of its kind to foresters, landowners, nurserymen, gardeners, etc., for it contains a host of valuable information relating to trees and shrubs, and especially from a forestry aspect. Much of the text of the issue for 1926 has been revised, and largely re-written by Mr. A. D. C. Le Sueur, Consultant in Forestry, and Forestry Advisor for Burnham Beeches to the Corporation of the City of London. There is a diary of practical operations in the forest and woodland for each month of the year, and this is followed by short articles on a multitudinous variety of subjects, such as the removal of tree stumps; plants for hedges; measurement of timber; preservation of timber by creosoting, etc.; a list of the largest trees in the Kingdom; trees and shrubs for coast protection; tables of weights and measures; notes on forestry law, etc. The diary gives a list of the principal foresters and assistant foresters in the country, and this is followed by the calendar and spaces for notes; the pages are five-and-a-quarter inches by three-and-a-quarter inches, allowing ample room for notes. The *Foresters' Diary* is issued by Messrs. W. Ryder and Son, Ltd., 8, Paternoster Row, E.C.4., price 3/6 net.

Fertilisation of the Primrose.—At a recent meeting of the Linnean Society, Mr. Eric Marsden Jones contributed a note on the pollination of the Primrose. In this he stated that arguments in favour of the pollination of Primula vulgaris, Huds., led to observations, by day and night, in a wood at Potterne, Wiltshire, in order to ascertain with the greatest degree of accuracy the part that day- and night-flying insects might play in the pollination of this plant. A series of systematic observations were made by day, between April 8 and May 15, 1925. The length of time spent in observing was in all twelve-and-a-half hours, and the number of important species of insects seen pollinating frequently was five. They comprise Bombus hortorum; Anthophora pilipes, ♂ and ♀; Bombylius major, ♂ and ♀; Bombylius discolor, ♂ and ♀; Rhingia campestris, ♂ and ♀. All these have a proboscis long enough to pollinate. The night observations extended from April 9 to May 15, 1925. Fifteen, visits were paid to the wood at various hours covering the entire night from 8.15 p,m. to 4.40 a.m. The time spent was sixteen hours twenty minutes, and the only visitors seen were Meligethes erythropus, Tachyporus salutus, and Forficula auricularia, which are of no value from a pollinating point of view. Besides these direct observations, a control experiment was also carried out. Two blocks of fifty plants each were covered alternately day and night. The patch from which insects were excluded at night produced 343 capsules, while the one exposed by night, and from which day-flying insects were excluded, produced only five, for which there is an explanation. This experiment lasted from April 19 to May 23. A further control experiment was carried out, six plants being covered day and night; these proved to be absolutely sterile. The conclusion drawn from the direct and experimental evidence prove that diurnal insects do pollinate efficiently, and that nocturnal Lepidoptera play no part whatever in the pollination of Primula vulgaris.

Public Parks and Gardens of Paris and Brussels.—The wider outlook which comes as a result of travelling in other countries than one's own is not so fully appreciated by British employers as it is by our continental friends. However, certain commercial firms understand the value attaching to travel, and they send promising men on visits of inspection to countries where industries similar to their own are conducted, and they regard the cost of such visits as a good investment. Long years ago, the Kew authorities appreciated the advantages to be derived from travelling abroad, and so Mr. Nicholson, Mr. Watson, Mr. Bean and other members of the garden staff—apart from the Directorate—have been sent at various times to other countries to obtain information and inspiration. If we remember rightly, the Glasgow Corporation sent the late Mr. Whitton to the continent on more than one occasion, and Edinburgh gave the late Mr. McHattie special leave for a similar purpose. Quite recently the Brighton Corporation directed its Chief Parks official, Mr. B. H. Maclaren, to visit the principal municipal parks, gardens and nurseries of Paris, and the parks and botanic gardens of Brussels. The visit was made last autumn, and a few weeks ago Mr. Maclaren presented his report to his Parks and Gardens Committee. The report is a model of conciseness and it is finely printed on excellent paper. In Paris, Mr. Maclaren visited the Bois de Boulogne, Champs Elysées, Champs de Mars, Tuileries Gardens, Jardin des Plantes, the Luxembourg Gardens, Jardin d'Acclimatation, Jardin de l'Observatoire, Bagatelle, Parc Montsoury, Parc Monceaux, the Buttes Chaumont and the Bois de Vincennes. He also visited several horticultural establishments and the parks and gardens at Versailles, St. Cloud and Fontainbleau. In Belgium, Mr. Maclaren's tour of inspection was limited to the Botanic Gardens, the park at Brussels, and the beautiful Bois de la Cambre. Antwerp should have been included in the itinerary. Mr. Maclaren generously acknowledges the assistance he received from the horticulturists of Paris and Brussels, and he makes a few comparisons between Brighton's open spaces and those of the cities he visited. We feel sure that Brighton will profit by Mr. Maclaren's visit to Paris and Brussels, and we suggest that other municipalities would do well to follow the example of Brighton in this respect.

Gold Medal Awarded to an American Pomologist.—The Massachusetts Horticultural Society has awarded its Large Gold Medal to Dr. Walter G. Kendall for his work in promoting interest in fruit culture and in the exhibition of fruits. There has not been a year in almost two decades in which Dr. Kendall has not made an exhibit at some exhibition of the Society which has awarded him the Gold Medal. For two successive years, in 1910 and 1911, he won the Silver Medal of the Society for the best garden visited by the Garden Committee.

Retirement of Mr. W. H. Miles.—This noted gardener is retiring from Lydney Park Gardens, of which he has had charge for a period of over twenty-four years. He came to Lydney Park as gardener to the late Charles Bathurst, Esq. —who was known as "The Squire"—the father of Lord Bledisloe, and was highly esteemed by all his family. Extensive alterations were carried out and Mr. Miles gained fame as a skilful cultivator and successful exhibitor. On the occasion of his retirement, Mr. Miles has been the recipient of valuable presents from Lord and Lady Bledisloe, from other members of their family, from the estate employees and local friends. Our readers will remember him as a contributor to these pages, and will be glad to learn that his son, Mr. H. W. Miles, M.Sc., Kirton, is a successful biologist. Mr. W. H. Miles is succeeded in the charge of Lydney Park Gardens by his friend, Mr. George Emmett, of Hampton Court Gardens, Hereford.

Tithe Act, 1925.—The Minister of Agriculture and Fisheries desires to state that the main provisions of the Tithe Act, 1925, which received the Royal Assent on the 22nd December, including the stabilisation of the annual value of tithe rentcharge at £105 per cent., and the transfer of ecclesiastical tithe rentcharge to Queen Anne's Bounty, do not come into force until the "appointed day"—a date not earlier than the 6th April, 1926—to be fixed by Order in Council.

It is anticipated that the "appointed day" will for these purposes be the 31st March, 1927, but ample notice will be given of the final decision on this point. The Act, therefore, makes no immediate alteration in the legal ownership of tithe rentcharge or in the bases of computation of the sums payable in respect of annual tithe rentcharge. For the present, the sum of £109 3s. 11d. continues to be payable for every £100 tithe rentcharge (par on commuted value) and half-yearly instalments of tithe rentcharge, which became payable on January 1, will be calculated on that basis.

New Year's Honours.—In the list of New Year's Honours few names occur of special interest to horticulturists and botanists. A well merited knighthood has been conferred upon Prof. J. Bretland Farmer, F.R.S., for special services rendered in scientific and industrial research, botany and agriculture; Baron Bledisloe, K.B.E., Parliamentary Secretary to the Ministry of Agriculture, becomes a member of the Privy Council; Mr. Samuel Simpson, Director of Agriculture in the Uganda Protectorate, receives the award of C.M.G., and Mr. William Waters Butler, Birmingham, has a baronetcy. Sir. W. W. Butler is an ardent horticulturist, owns a fine collection of Orchids and is a member of the council of the Birmingham University. He was at one time a member of the Royal Horticultural Society's Orchid Committee.

Mr. Collingwood Ingram's Visit to Japan.—Mr. Collingwood Ingram, of The Grange, Benenden, Kent, whose unique, Japanese flowering-Cherry is illustrated and described in the present issue (see p. 27), is starting on a visit to Japan for the special purpose of studying the flowering Cherries—a group of interesting and beautiful plants in which he has taken great interest for many years.

Appointments for the Ensuing Week.—Monday, January 11: United Horticultural Benefit and Provident Society's meeting. Tuesday, January 12: Royal Horticultural Society's Committees meet; Jersey Gardeners' Society's meeting Wednesday, January 13: Glasgow and West of Scotland Horticultural Society's lecture; Wimbledon Gardeners' Society's meeting. Thursday, January 14, Crowthorne Horticultural Society's lecture. Friday, January 15: Orchid Club meeting. Saturday, January 16: Newcastle Horticultural Mutual Improvement Society's annual dinner.

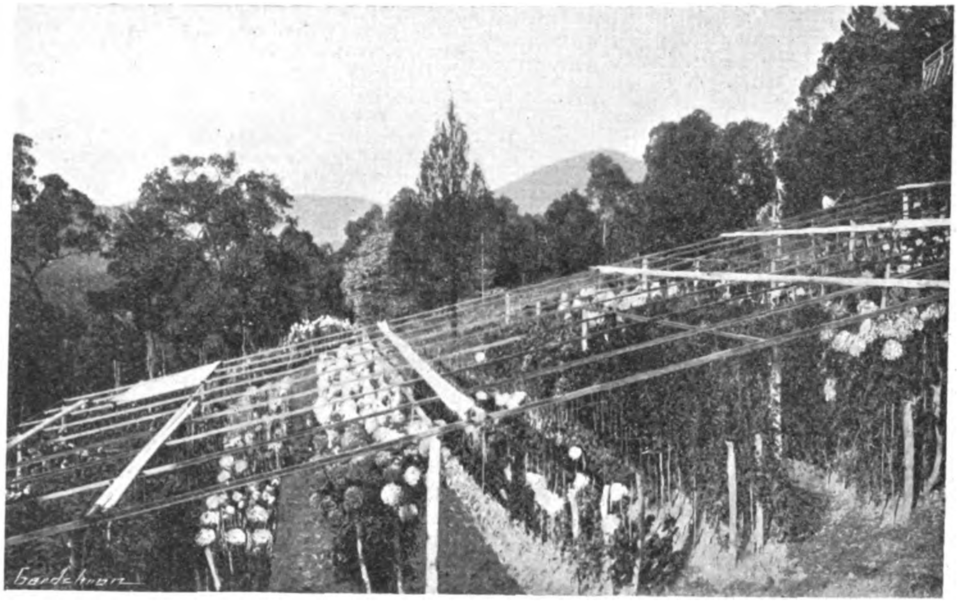

FIG. 10.—MR. THOS. POCKETT'S CHRYSANTHEMUMS IN AUSTRALIA.
(see p. 24.)

"Gardeners' Chronicle" Seventy-five Years Ago.—*The Great Exhibition Building of* 1851.—If the marvellous building now rearing its head in Hyde Park has no other merit than that of exhibiting what can be done in England under the influence of a fixed resolution, it would scarcely claim a notice in this part of our Journal; however worthy of admiration it might be, its structure would necessarily be left for discussion elsewhere. But it will be found, beyond all doubt, to have a most important bearing upon horticulture, as, indeed, its garden origin suggests. When Mr. Paxton constructed at Chatsworth the Victoria House, fully described in our last volume, page 548, he laid the foundation of a series of changes in the plans of conservatories, the end of which will doubtless be the gradual removal of all those lean-to, span-roofed or upright fronted plant houses with which gardens are now decorated. It will probably be found too, that he will have introduced into very general use those winter gardens which so many have sought for and so few have found. The difficulty that has hitherto been experienced in making a winter garden has been its expense. The very term winter garden implies the enclosure of a considerable area beneath a glass roof; but the moment a large area is spoken of, the architect casts his eyes upwards, and insists upon the height bearing a certain proportion to the base. And this compels the further introduction of costly heating apparatus; so that between massive brickwork, ponderous iron work, and a labyrinth of hot-water-pipes, it is fortunate if the building is prepared for receiving plants at a cost of less than a pound sterling per superficial foot of the area. We entertain no doubt that, in general, the expense is far greater. At this rate, a plant-house, 100 feet long and thirty feet wide, would cost £3,000 at the least; and it would require nearly £44,000 to cover an acre in like manner. But when we look at the Victoria House in Hyde Park, we find that about eighteen acres are covered for less per acre than a quarter the sum above mentioned; and of this sum we apprehend that more than half has been on account of the galleries and aisles, required to produce the magnificent effect which we all so much admire. It is not heated, it is true, and for that an allowance must be made; but, giving any reasonable margin for heating, still the difference of cost is excessive. And it is to this that the attention of the country should be directed. *Gard. Chron., January* 11, 1851.

The Week's Work.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Trichopilia.—The best known members of this very interesting genus of Orchids, and the most frequently found in Orchid collections, are T. suavis, T. coccinea, T. tortilis, T. Backhousiana and T. laxa. The majority of those mentioned will by now have completed their growths, and should be afforded only sufficient water to keep their pseudo-bulbs plump. If they are kept too moist at this period, the pseudo-bulbs and leaves will become spotted. During the plants' season of rest they should be placed in a light position in a house having an intermediate temperature, but not exposed to direct sunlight, as this would cause the foliage to assume a yellow, unhealthy colour. The necessary re-potting should be done soon after new growth commences. Orchid pans form suitable receptacles, and they should be well-drained. Use a mixture of Osmunda-fibre, chopped into short portions, and Sphagnum-moss, as a rooting medium. In re-potting, elevate the plant somewhat above the rim of the receptacle, so that when watering moisture will not settle in or around the young growths, as they rot readily. The sweetly-scented T. fragrans is sending up flower-spikes, and will soon be in bloom. This Orchid is worthy of a place in any collection. It grows well in the warmest part of the Odontoglossum house. T. rostrata will thrive under similarly cool conditions.

Brazilian Miltonias.—The principal species and natural hybrids belonging to this group, which include M. Regnellii, M. Clowesii and M. Russellianum, should be examined, and any plants that require it may be re-potted. M. spectabilis and its variety Moreliana, are best grown in shallow pans, with wire handles attached, and suspended from the roof in the intermediate house. They have a creeping rhizome and are shallow-rooting; therefore only a thin layer of compost is needed. The useless back pseudo-bulbs should be cut away, leaving only two or three behind each growing point. The plants should be kept pegged down to the soil as they extend. Overgrown specimens that have become bare in their centres may be broken up and the portions potted up afresh to form specimens of the desired size.

THE FLOWER GARDEN.

By F. C. PUDDLE, Gardener to LORD ABERCONWAY, Bodnant, Taly-Cafn, North Wales.

Annuals.—When compiling the seed order for the flower garden the selection of suitable annuals requires careful consideration. There is such a wide range to choose from that suitable annuals may be found for almost any position, and they are most useful for filling blank spaces in beds and borders. To do them full justice however, they require a border to themselves, and borders of annuals are especially useful in small gardens, and those situated near large towns, where many herbaceous plants, such as Phloxes, only languish. Where glass accommodation is limited, very interesting borders may be made entirely of hardy annuals, but the finest effect is produced when both hardy and half-hardy kinds are used. The common practice of sowing hardy annuals where they are to flower is neither necessary nor advisable, as, with a few exceptions, they transplant readily, and in gardens where room is restricted it is possible to have a display of spring flowers, and follow with annuals. Suitable kinds for such borders are:—Clarkias, Godetias, Larkspurs, Coreopsis, Nigellas, Nemesias, Asters, Phlox Drummondii, Anagallis, Lobelia ramosa, Salpiglossis, Viscarias, Alonsoas, Diascia Barberae, annual Chrysanthemums and Brachycome iberidifolia. With a selection of varieties of these kinds all the glories of artistic arrangements and pleasing colour schemes may be obtained at a very small expense. Annuals are also very useful for filling odd corners of the garden, and it is a very arid spot which will not support plants of Salvia Bluebeard and Calendula Orange King, that make an effective colour combination.

Liliums.—Importations of Japanese Lilies will now be arriving, and those destined for the flower garden will repay a little preferential treatment. To plant the bulbs, which have already been weakened by their long journey and probably bruised in transit, direct into cold, damp soil, will hasten any tendency to decay, even if they are surrounded with sand. The bulbs should be examined when they are received, badly bruised tissue cut away, and the wounds rubbed with a little fine lime. They may then be potted in a sandy compost and placed in cold frames with the pots plunged to the rim in ashes. Keep them quite cool, so that they will not be forced into premature growth, but so soon as this commences they may be planted in their permanent quarters. The two beautiful Lilies, L. regale and L. philippinense var. formosanum, may be raised easily from seeds, the bulbs flowering when from two to three years old. The seeds should be sown at once in gentle warmth, and when the seedlings are large enough, they should be pricked out in pans or boxes and grown on in a cool frame. When permanently planting Lilium regale, choose a sunny situation, but Lilium philippinense var. formosanum prefers a sheltered place in partial shade. This last is, I believe, much hardier than is generally imagined.

PLANTS UNDER GLASS.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

Hippeastrums.—Plants that were plunged in a warm bed a few weeks ago are throwing up their flower scapes. If not already done a batch, according to requirements, should be placed in a warm plunge-bed. Bulbs that do not require re-potting should be selected for early flowering. It is also an advantage to select plants that were started early last year, because, having finished their growth early, they will respond the more readily when introduced to heat. Before placing them in the plunge-bed they should be soaked thoroughly at the roots and examined for mealy bug; they should then have some of the top soil removed, substituting a top-dressing of good loam mixed with a little leaf-mould and sand, and a liberal quantity of bone-meal. Plants that require re-potting should have all the soil shaken away, and decayed roots trimmed off, after examining them for mealy bug. They should be potted in a compost consisting of three parts good loam, and one-third leaf-mould and clean, sharp sand, with a six-inch potful of bone-meal to every bushel of soil. The pots should be plunged in a bed of fibre, with bottom heat; at this stage careful watering is necessary, and little or no moisture should be given the roots until a quantity of new roots have developed and top growth commenced. This applies to all newly-potted bulbs, many of which are ruined at an early stage through the soil getting wet and stagnant before new roots are formed.

Ardisia crenata.—This plant produces its bright red fruits freely, and is very valuable for greenhouse or indoor decoration, as specimens remain in good condition for many months. As it takes three years to produce a good fruiting plant from seed, a batch should be raised each year to maintain a succession. This Ardisia may also be propagated from cuttings made of the leading shoots, for although lateral shoots root readily, they never develop a leader. If there is a stock of old plants, the tops may be used as cuttings; pieces six to eight inches long will root readily in a propagating case furnished with plenty of bottom heat. By this means, at least one year is gained in the production of good plants. If it is desired to raise a stock from seeds, the latter should be sown now, as they are somewhat slow of germination, but their development may be hastened by soaking them for twelve hours in warm water, and plunging the seed pots in a warm propagating case. This plant succeeds readily in any good potting compost, and in its younger stages is best grown in a temperature of about 60°.

Tuberous-rooted Begonias.—Where it is desired to raise a stock of these plants from seeds, the latter should be sown sometime during this month. The seed-pans should be filled with a light, sandy compost, made moderately firm, and the soil should be watered with a fine-rose can a few hours before sowing the seeds. The dust-like seeds should be carefully distributed over the surface, and should not be covered with soil. Place a piece of glass over the seed-pan and give shade until germination takes place. When the seedlings are large enough to handle, they should be transferred, in tufts, to fresh soil in pans or shallow boxes. When next handled, it is easy to separate the young plants singly. Success depends largely in growing them on quickly without a check, and frequent shifts into fresh compost are essential. Grown on in a temperature of 60°, the plants should be large enough to plant out in frames during April, from whence a number may be lifted later and potted for furnishing a display in the conservatory towards the end of summer, when they make a good succession to the earlier plants grown from old tubers; if desired, the seedlings may be grown straight on in pots. Where an early batch is required, the desired number of dry tubers should now be started in a warm house.

HARDY FRUIT GARDEN.

By W. AUTON, Gardener to VISCOUNT ELVEDEN, Pyrford Court, Woking, Surrey.

Planting.—Where considerable planting schemes are contemplated, a good deal of the work has, perforce, been deferred, and every effort should be made to complete these arrears whenever weather conditions are favourable. Where preparation was made in the autumn the soil is now in good condition, enabling the work to be carried out expeditiously when the weather is a little drier. See that the roots are spread out in the holes so that they occupy as large a feeding area as possible, and if any roots have been bruised in lifting, cut them back with a sharp knife to sound tissue. Care should be taken that the tree is not planted too deeply; on very heavy soils it is a good plan to plant fruit trees on a slight mound. To facilitate planting on such soils, it is wise to have little dry loam available to enable the planter to plant firmly and make a good finish. So soon as the work is completed mulch all trees with decayed manure.

Pruning.—Where the pruning of Apples and Pears has not been completed, the work should be done whenever favourable conditions prevail. No hard and fast rule can be laid down as to the degree of pruning necessary, but, where summer pruning has been practised, little winter pruning will be necessary, beyond removing all dead, diseased or badly placed shoots, and in some cases thinning the spurs. A knowledge of varieties and their behaviour under various conditions is also necessary to enable the operator to accomplish the work successfully. Very hard winter pruning should not be done, as it results in gross growths which have no tendency to fruitfulness; the ideal to aim at is so to govern the growth of the tree that the need of winter pruning is reduced to a minimum. In the case of trees growing on walls and espaliers all ties should be examined, and it is a good plan to renew them all entirely, as old ties frequently harbour insects and make it difficult for birds or sprays to reach them. When overhead work is completed, the borders should be cleaned and lightly pricked over, when a mulch of rotten manure may be applied. When pruning, save all scions which may be required for grafting in the spring, and lay them in by the heels in a sheltered and shady position. Success in future operations with the scions largely consists in keeping them dormant, as if they can be kept in a state of quiescence until wanted for use their chances of growth are good.

FRUITS UNDER GLASS.

By T. PATEMAN, Gardener to SIR CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Cleansing of Fruit Houses.—With the advent of the New Year, every effort should be made to thoroughly cleanse all fruit houses which have not already received this attention. This is a most important cultural detail, especially where vines or fruit trees have been attacked by red spider or mealy bug. The latter pest may be eradicated, now that the trees or vines are in a dormant condition, by cyaniding the house; this operation is best carried out before untying the trees or vines, and again after all loose bark has been removed from the latter. Cyaniding is, of course, only necessary when the occupants of the house have been badly infested with this pest. The wood-work of the house should be painted, if necessary, and the wall coated with hot lime-wash mixed with paraffin. The mixture should be worked well into the crevices of the wall with a stiff brush. When this work has been completed, remove the surface soil of the border to the depth of two inches and add new material.

Temperatures.—Fruit houses that have been closed, and the trees started into growth, should not be kept too warm. In the case of Peaches, high temperature promoted by fire-heat may lead to the dropping of the buds, and with vines it may tend to cause weak growth. On bright days the temperature raised by solar heat will prove beneficial to the trees. This need cause no alarm whatever, provided the trees have received no check through lack of moisture at the roots, or any other cause. Although the trees should never be allowed to become excessively dry at the roots, they will require very little water at this stage. On bright days they may be sprayed overhead, and this should be done about noon. When the temperature of the house rises to 55° with solar heat, a little air may be admitted for a short time, but the house should be closed early in the afternoon to conserve the sun's warmth as much as possible. On mild nights the temperature may be 50°, but in frosty weather it may be allowed to drop to 45°, rather than overheat the hot-water pipes.

THE KITCHEN GARDEN.

By F. STREETER, Gardener to MAJOR ALBERT PAM, Wormley Bury, Broxbourne.

Exhibition Onions.—To produce large, well-ripened Onions for early shows, the seeds should now be sown in boxes. The latter should be well-drained and filled to within half-an-inch of the top with the following compost:—two parts rich fibrous loam, one part leaf-mould, and one part coarse silver sand. Make the compost firm, and select the finest seeds, placing them half to three-quarters-of-an-inch apart. Just cover the seeds with very fine soil, and place the boxes in a fruit house that has just been started, having a temperature of 45° at night and 50° by day. Cover the boxes with sheets of glass and shade with paper until the seedlings appear, when they should be exposed fully to the light. Provided the soil is in proper condition for sowing, water will not be required for the first forty-eight hours. Wipe the moisture from the glass covering the boxes the first thing every morning. Attention to minute details should be given at all times. Undoubtedly, the finest varieties for this purpose are a fine form of selected Ailsa Craig and Premier. With this sowing sow also some seeds, broadcast, in boxes, to obtain young plants for use as salad.

Cauliflower.—Give the autumn-sown Cauliflower plants growing in frames plenty of air at all times when weather conditions permit. Slightly prick over the surface and dust it with soot once weekly. Remove damp and decaying foliage, taking care not to injure or loosen the stems. Make a further sowing of two early maturing varieties in well-drained boxes, to form a succession to the above. Sow thinly, and cover the seeds with finely-sifted burned earth. This will be found an excellent preventive of the dreaded blackleg disease. Place the seed-boxes in a newly started fruit house until the seeds have germinated, then remove them to cool quarters.

Lettuce.—Sow sufficient Lettuce seeds for the requirements of the establishment. The young plants will mature quickly if placed between the rows of Potatos, etc., over the newly-made hot-beds (in heated pits). Sow sufficient Mustard and Cress for fresh supplies of these salads weekly.

FOR NORTHERN GARDENERS.

By A. T. HARRISON, Gardener to the MARQUIS OF AILSA, Culzean Castle, Maybole, Ayrshire.

Pleasure Grounds.—All fallen leaves not previously removed should be raked in heaps and either carted to the frame ground for use in the making of hot-beds, or deposited in some well-screened depôt for the formation of leaf-mould for future use. Where the grounds to be cleared of fallen leaves are planted with Snowdrops, Narcissi, etc., it is important that this work should be done early, as these plants are now well through the soil, and much damage may be done to the tender growth if the removal of the leaves is longer delayed.

Seed Potatos.—The earliest varieties of Potatos are sprouting rapidly, therefore the tubers should be arranged in single layers, and exposed to plenty of light and air, as otherwise the growths become attenuated and weak. Care and attention are necessary, however, to see that they are kept free from frost, as one night's neglect may spell disaster: the earliest and best sets will be the ones to suffer most, and thus defer the early Potato crop for a month or more. Potato planting begins early in this district, the middle of February being the usual time for commencing the work in fields.

Early Peas.—The first dish of green Peas is always appreciated, and the middle of January is a good time to make the first sowing, but as outside conditions do not permit of this being done in the open the seeds should be sown in long, narrow boxes with detachable bottoms under glass. The seedlings may be transferred readily from the boxes to their permanent quarters later. If the boxes are made about six feet long, and slightly wider at the bottom than at the top, it will facilitate the process of transferring the plants to the shallow trenches prepared for them without much disturbance. Cover the seeds with fully an inch of soil and place the boxes in a cool structure until germination takes place, when they may be placed outside in a sheltered corner. Suitable varieties for this sowing are Pioneer and Hundredfold.

ROSE GARDEN.

ROSA CORYMBULOSA.

THIS pretty Rose species was named by the late Mr. R. A. Rolfe, who described it from plants raised at Kew form seeds collected by Mr. E. H. Wilson in Western China, in the autumn of 1907. The description accompanies a fine illustration in *Bot. Mag.*, t. 8566, reproduced from a drawing by Miss Smith. Judged only from this picture Rosa corymbulosa promises to be not only a good garden plant on its own account, but also the progenitor of a useful race of Roses. The flowers are described as "numerous, in small corymbs towards the ends of the branches." In the *Bot. Mag.* figure there are three corymbs, with four, eight and nine flowers respectively, all on a six-inch length of branch. The flowers are pink, from three-quarters of an inch to one inch wide; each petal is obcordate, the "notch" being a prominent feature, and making each petal bi-lobed at the broad, outer end. The leaves are rather closely set, with serrated margins and a glaucous undersurface.

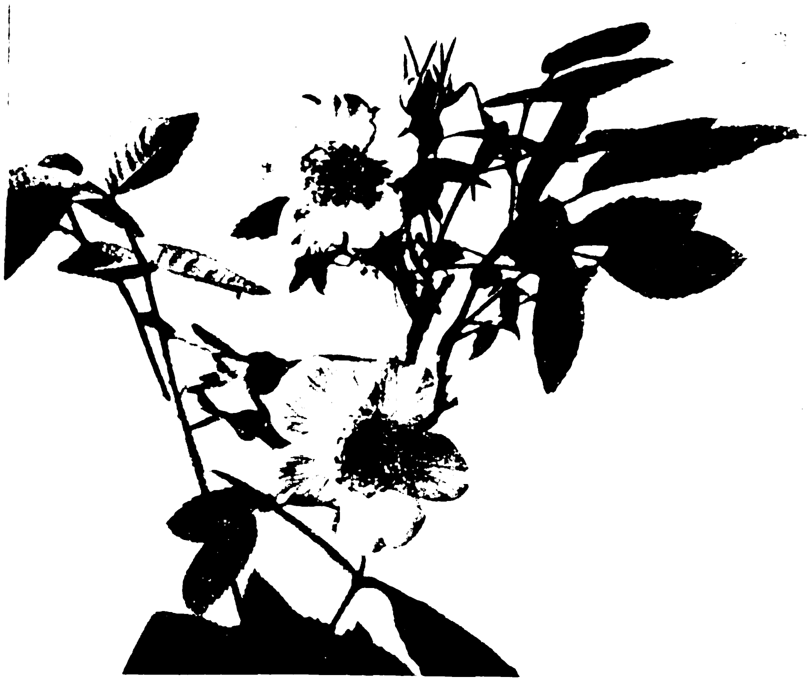

FIG. 11.—ROSA CORYMBULOSA.

Possibly some forms of R. corymbulosa are better than others, and, if so, selected seedlings might add to the beauty of our gardens. Unfortunately, there is a statement in *Plantae Wilsonianae* to the effect that the wild plants of R. corymbulosa "have much smaller corymbs than that figured by Rolfe, indeed, the flowers are often solitary." There seems to be no doubt as to the hardiness of this Rose, therefore those who interest themselves in hybridisation might well consider its possibilities, notwithstanding the wide differences suggested by Fig. 11 and the *Bot. Mag.* illustration.

TREES AND SHRUBS.

HYDRANGEA PANICULATA GRANDIFLORA.

This is a very desirable hardy shrub, and most decorative when planted as single specimens or in groups of three in the herbaceous border. It bears very large panicles of white flowers, the inflorescences often being a foot in length. The flowering season is late summer, and the plants will furnish a display extending over six to eight weeks.

In order to obtain the best results this Hydrangea should be planted in rich, fairly moist soil, and should be cut hard back in spring. *W. Logan.*

ERICA VAGANS ALBA.

The appearance of the new white variety of Erica vagans, named Lyonesse, mentioned by your contributor, *A. T. J.*, on p. 468, vol. LXXVIII, will be hailed with pleasure by many admirers of the Cornish Heath, which deserves all the praise bestowed upon it by your able correspondent.

One great defect in the older white varieties is the presence of the protruding, coloured anthers which detract from the purity of the flower. I should like to know if Lyonesse is free from this defect, or in what other respects it shows an improvement on other white forms. The varieties St. Keverne and Mrs. Maxwell are indeed acquisitions. *S. Arnott.*

RUBUS IRENAEUS.

This evergreen, trailing shrub is one not often seen in gardens, yet, having grown it in the woodland for a few years, it promises to be a valuable and ornamental subject for covering the ground in shaded or open situations.

R. irenaeus is quite prostrate, having trailing, slender, pale green, downy stems furnished with large, heart-shaped leaves suggestive of those of the Coltsfoot. But, unlike those of the latter, the leaves are a rich green and very glossy, whilst the underparts are covered by a greyish felt which tends to a browner hue with age. The foliage is distinct and handsome, especially in winter, and it appears to be absolutely frost-proof. So far, my plants of R. irenaeus have not flowered, and it would be interesting to know under what conditions the plant does so and bears fruit in this country. It was introduced from Central China in 1900 by Mr. E. H. Wilson. *J.*

MUEHLENBECKIAS.

Eminent authorities declare that there are only two species of Muehlenbeckia in general cultivation in this country, and the humbler amateur has to abide by that decision. Even so, there is such a distinct difference between M. complexa and M. varians (said to be a form of the latter) of the lists that for all practical purposes these two may be considered apart. Doubtless there are other, and intermediate, forms, but with me I have always found M. complexa a much inferior shrub to M. varians, in that it is stiffer in growth and lacks the elegance of its rival. While the former generally has a tendency to grow downwards, or remain more or less prostrate, and while it often makes a dense, unwieldy and not particularly attractive mass of its wiry branches, M. varians is a most willing climber; its more slender branches have a decidedly twining inclination, they will scale a wall with the most meagre of assistance in the way of support, and often make six feet of growth in a season. Moreover, M varians, as usually sent out by nurserymen, has fiddle-shaped leaves which never fail to arrest attention.

Though the above have not flowered in this garden, the very dwarf M. axillaris never fails to yield an abundance of its tiny yellow-green tufts, and these always produce the little translucent fruits which look like beads of dew. This species is, indeed, a very delightful rock garden shrub. It is deciduous, like the foregoing, quite hardy in most places, and by no means difficult to establish. In height it does not exceed about two inches, but it will spread in any light, stony soil, and cover in the course of many years a space of perhaps a square foot. This and other kinds are easily propagated by cuttings or layers. *J., N. Wales.*

FLORISTS' FLOWERS.

MR. POCKETT'S CHRYSANTHEMUMS.

From Mr. Thomas W. Pockett, the famous raiser of Chrysanthemums, we have received a cheery letter and a photograph of his Chrysanthemums, reproduced in Fig. 10.

He writes: "This is the way I grow my Chrysanthemums at Healesville, Victoria, Australia. The row of plants on the left centre of the picture is a fair sample of what the others were before they were cut. As you will observe, provision is made for covering the plants when there is too much rain, very heavy dews, or bright sunshine. The plants in the distance, without protection of any kind, are of the variety Thomas W. Pockett. The indigenous trees are mostly Eucalyptus and Acacia, but the somewhat conically shaped tree in the centre is what we call the Native Cherry, which bears small fruits with the stones formed on the outsides of the fruits. My place is situated in the mountains, about thirty-five miles from Melbourne, consequently we are comparatively free from frosts and fogs. Most of the seed plants are placed on the balcony so that they are handy for the work of hand pollenisation, and for this purpose the position is ideal. All good wishes for 1926 to my many friends in the home-country."

RUST ON CHRYSANTHEMUMS.

This troublesome disease is not easily cured, and where plants are badly infested, probably the best and only method to adopt is to burn the whole collection so soon as the plants have flowered. Fresh stocks should then be obtained from a reliable source. The growing quarters may also be changed with advantage. This applies to all stages of growth, from the date of inserting the cuttings to the time when the plants are ready for housing. The propagating frame should be cool and airy, and from the time the plants are in the frames to the final housing of them they should never be grown under stuffy or crowded conditions.

I struggled along for several years with a rust-infested stock, and incidentally tried numerous fungicides, which the manufacturers claimed would cure the disease, without any beneficial result.

A few years ago a neighbouring gardener begged cuttings, as he was anxious to get a stock of plants. Rust never put in an appearance, possibly because no attempt was made at high cultivation, but more probably because the plants were growing on new ground. When the benefits obtained by the change were noted, I decided to renew the whole of my collection from reliable sources. The result was satisfactory, no trace of disease being found the next season. This immunity may be attributed in part to the fact that new quarters, more elevated and open, were secured on which to grow the plants when in their flowering pots.

In private establishments, Chrysanthemums are often grouped in corridors and living rooms, with the result that cuttings from them are weak. Such plants do not produce the most satisfactory cuttings for maintaining a healthy and vigorous stock. It is desirable, where time can be spared for the purpose, to put a number of plants in the open ground. These special stools should be lifted in the autumn, placed in a cool house or pit and used for purposes of propagation. *Charles Hodgson.*

ALPINE GARDEN.

POLYGALA VULGARIS.

It is rather surprising that the charming little Milkwort of our native heathlands, Polygala vulgaris, has never found its way into British rock gardens, or into the catalogues of nurserymen who specialise in alpine and rock plants. It is even a matter for surprise to me that I have myself, up to now, overlooked the merits of this beautiful little plant. I think perhaps I half imagined that it was an annual or a parasite, or had some tiresome kink of that sort. When dug up it displays a rather wiry, tap-like root system, not unlike that of some of the annual or biennial Gentians and Centaureas. But I have tried a few collected plants in my rock garden, and although I planted them with little faith, they have proved quite easy to establish, and as perennial as the botany books state they are. It is a neat little plant, making a close evergreen mat of dark green foliage, and producing in July and August little two-inch to three-inch flower spikes. The flowers are difficult to describe in clear unbotanical language, but perhaps it will convey some idea of what they are like if I state that they are like tiny Gorse blossoms, with a fringe or beard where the keel of the Gorse flowers would be. The colour of the flower varies greatly. The normal or commonest colour is blue, and a pure bright blue at that, whilst pink varieties are commonly found, as well as pinkish lilac and pure white.

The only approach to finding this excellent plant in cultivation, apart from my few collected specimens, is that one or two alpine specialists list a rather rare, local, chalk-down variety of Polygala vulgaris called calcarea. This is, if anything, a better plant than the common type, forming a more definite mat of foliage, flowering very freely, and giving flowers of a bright, pure, clear, sapphire blue. Its time of flowering is May and June. The variety calcarea is recognised by botanists, and is described in Bentham and Hooker's *British Flora.*

There are some splendid species of Polygala which grow in the Alps, like magnified forms of P. vulgaris, six to nine inches high, with pink, blue, and bright magenta flowers, and they would make glorious plants for the rock garden. I have tried to bring them home several times, but have never succeeded in establishing them. Farrer speaks highly of these plants—of their brilliance and beauty—but guardedly as to their culture and nomenclature. He makes but passing mention of P. vulgaris, and does not mention P. v. calcarea at all. I think a determined effort should be made to introduce these splendid alpine Milkworts; but in the meantime let me strongly recommend rock gardeners to collect and try the dainty British species, and especially the hearty, tufted calcarea variety of it. *Clarence Elliott, Stevenage.*

ROCKERY SHRUBS.

A judicious selection of dwarf-growing shrubs adds materially to the general appearance and effectiveness of the rock garden.

The following are a few of the hardiest and most desirable subjects that may be utilised for the purpose:—Abies balsamea hudsonia, a neat, congested bush; Cupressus Lawsoniana Forstschiana and C. L. nana, both miniature bushes; Juniperus communis alpina (nana), J. Sabina, Picea excelsa var. Gregoryana, an attractive and miniature Spruce Fir; P. e. pygmaea, P. e. Maxwellii, P. e. pumila glauca, a dense-growing dwarf plant, with blue-green foliage; Retinospora filifera nana; R. filifera aurea, with light yellow foliage; R. obtusa nana aurea, with golden foliage Taxus repandens, an effective, prostrate-growing Yew; and Thuja occidentalis Rheingold, a variety with golden foliage.

A few effective, flowering shrubs include Azalea amoena, A. rosaeflora, Berberis Darwinii, B. Wilsonae, Cistus crispus, C. florentinus, Cotoneaster microphylla, C. humifusa, Hypericum Moserianum, and the variegated form, tricolor; Margyricarpus setosus, Perowskia atriplicifolia, Veronica cupressoides, V. loganioides, and V. Hectori. *W. Logan.*

ORCHID NOTES AND GLEANINGS.

CALANTHE HEXHAM LAD.

Clive Cookson, Esq., Nether Warden, Hexham (gr. Mr. W. J. Stables), sends a flower of the third of his beautiful C. Angela crosses named C. Hexham Lad, which is one of the largest and most richly-coloured of winter-flowering Calanthes.

The whole flower is deep ruby-crimson, the broadly-developed lip being slightly the darker and having a lighter shade on each side of the crest. The apex of the column is white, making an attractive centre.

The new hybrid is the result of crossing C. Angela and C. Sedenii burfordiense, following the lines of the C. Ruby section, so admirably worked by Mr. Cookson's father, the late N. C. Cookson, Esq.

CYPRIPEDIUM SPECIOSUM.

Formerly often confused with Cypripedium macranthum, C. speciosum was cultivated in British gardens for many years before Mr. R. A. Rolfe described it in the *Kew Bulletin*, and it was figured in the *Bot. Mag.* (t. 8386), during 1911. It is a Japanese species and undoubtedly allied to C. macranthum, which, however, is not found in Japan. Those who can cultivate C. macranthum successfully should find no difficulty in growing C. speciosum (Fig. 12). The latter has stems from eight inches to sixteen inches tall, with sessile, more or less ovate, ciliolate, pubescent and plicate leaves. The large flowers, borne singly at the apex of growth, are handsome, usually flesh pink, or even deeper, though sometimes paler, and with rose veinings. The dorsal sepal is about one-and-a-half inch long and the ventral sepal only a trifle shorter, with a bifid tip. The petals are also about one-and-a-half inch long and nearly three-quarters-of-an-inch broad, while the big globose or inflated lip is a very showy feature of the flower, its rosy pink colouring being set off by the white staminode. At the base of the dorsal sepal and of the petals there are numerous dots of a deeper shade than the ground colour.

The late Mr. Reginald Farrar wrote enthusiastically of C. speciosum:—"The sight of this, glowing with its noble baggy blossoms of pink and white among the rough grasses on the open downs above Ikao, or round the feet of Fuji-san, or peering here and there among the light bushes that they share at Shoji, with Paeonia japonica waving its pearly cups above the Slippers, is enough to make any gardener resolve that no cost shall be too great for the procuring and success of C. speciosum." June is the flowering period of this fine species.

IRIS GARDEN.

IRIS DELAVAYI.

It is many years since I first acquired Iris Delavayi, then a new plant on the market, and grew it in an ordinary border in the garden—rather a dry one. The result was not pleasing, as the plant flowered sparsely and the blooms proved disappointing. Had I known then what I know now, that the hollow-stemmed Irises generally love moisture, I would have planted I. Delavayi by the side of a small pond, where it would have had the abundant supply of moisture which it requires to do it justice.

Some time afterwards I saw it in a place where it was more at home, and then, with a plentiful supply of water, it grew to the height of four feet and produced plenty of its deep purple flowers, marked with white blotches. It is true, as has been remarked by an eminent writer on these grand flowers, that the blooms of the wild plants are comparatively small, but more satisfactory hybrids have been raised which give not only finer flowers, but bloom with greater freedom. Given the plentiful supply of moisture suggested above and a soil of moderate fertility, I. Delavayi will yield satisfaction to the lover of those forms of Iris which are not to be found in every garden, but which are not expensive to purchase, and which grow well under favourable conditions.

I. Delavayi may be planted in the spring; a sunny place should be selected if plenty of water is available, but one with a little shade if this is not to be had. *S. Arnott.*

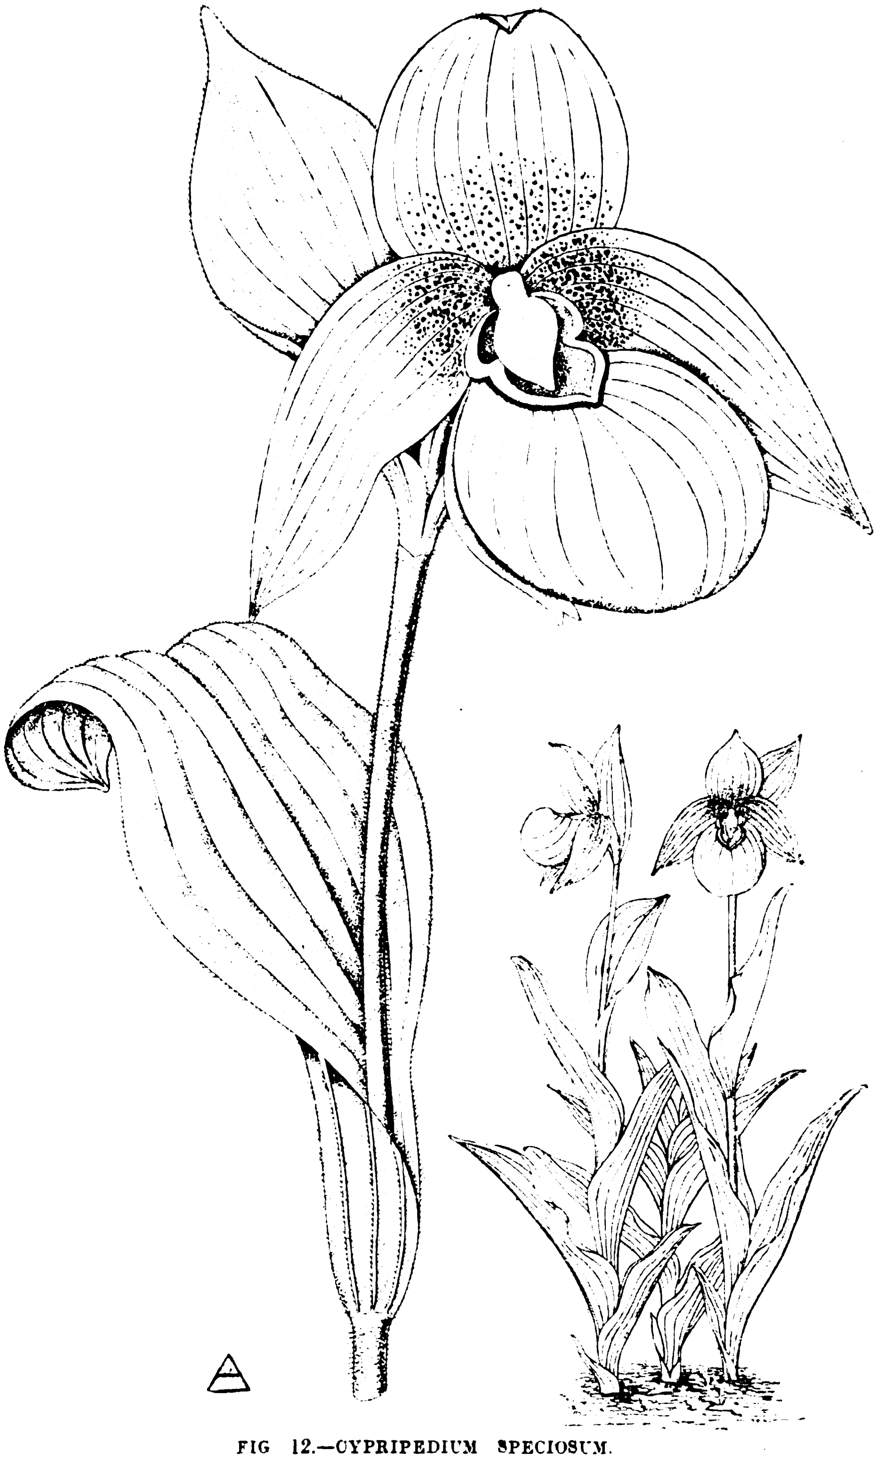

FIG 12.—CYPRIPEDIUM SPECIOSUM.

IRIS GRACILIPES.

This little Japanese Iris is one of the daintiest and most beautiful of its distinguished race, and, unlike many of the dwarf species, it gives a profuse display of blossom, and will remain in bloom for a longer period than any other rock-garden, rhizomatous Iris that I have grown. Even its leafage is exceedingly graceful. The grassy, yellow-green leaves of three to four inches, waving this way and that with the utmost elegance, will in a few years cover a wide pocket with their tender verdure.

The flowering season of this Iris is late spring and early summer, and there is nothing prettier in the rock garden than quantities of these slender-stemmed blossoms of delicate lilac-blue, finely veined and adorned with a yellow beard, hovering with their own inimitable grace just above the foliage.

I have found I. gracilipes to be of the easiest possible culture in any well-drained, gritty soil with full exposure. It will even thrive wedged in between rocks, for it is as indifferent to drought as it is to wet or frost.

This exquisite gem has been likened to I. tectorum in miniature. But, while it may be said to "feature" the Roof-Iris in its leafage, allowance being made for the vast difference in size, it is much more elegant in flower and certainly a more reliable bloomer. To my eye, the blossoms of I. gracilipes in their general appearance much more nearly resemble those of the great Flag Iris of Japan, if one can imagine the latter reduced to a diameter of about one-and-a-half inch. *J.*

HARDY FLOWERS FOR EXHIBITION.

The plants dealt with in my article which appeared in *The Gardeners' Chronicle* on December 5 last, belong chiefly to what may conveniently be termed miscellaneous subjects, and not to the big and popular families. It is wise policy to make good use of uncommon subjects, but nevertheless, prudence bids one have due regard for Pyrethrums, Phloxes, Delphiniums and other effective flowers. It is imperative, however, that these should be thoroughly up-to-date, or, at least, really good varieties should be staged, and in view of the fact that every competitor may be expected to make a strong feature of each popular family, according to season, effort must be made to produce the very best flowers by good culture.

For June shows, of which York Gala is the chief, good use may be made of Irises, but this does not mean that a third of the stand may be occupied by these flowers. I do not urge that in order to score full points for Irises in an exhibit of two dozen vases of hardy flowers it will be necessary to purchase the latest and most expensive novelties. One variety that is very hard to beat is Lord of June, and it cannot be far short of twenty years since Mr. Yeld took me down a tent at York to ask my opinion of this most appropriately named flower. To-day, as then, it is, in my opinion, good enough for the finest exhibit one may wish to stage.

Paeonies provide serviceable flowers for those who have well-established plants, but one point about them is, if they are really well-cultivated, and the doubles are brought to fine size, they require something more than an ordinary flower vase in which to arrange them to good effect. When faced with two sets of Paeonies, one flopping over the surrounding flowers, and the other with stems cut short and rammed deeply into the vase, it is difficult to determine which should be most penalised. When well-staged, few flowers can surpass Paeonies. The lobster-red, single-flowered Paeony lobata will make a magnificent vase, but some care must be exercised in choosing its immediate neighbours, for it is easily possible to counteract the advantage of its special attraction by destroying the finest effect of some other subject. I am aware that lobster-red is not a good description, for the colour is more dazzling and brilliant than any lobster ever was, and I doubt if words have ever conveyed a correct idea of its richness and splendour.

In Pyrethrums, whatever else may be omitted, Eileen May Robinson will make its mark, and if another single is required, Harold will serve the purpose thoroughly well. The white sport of Queen Mary is a double variety that anyone might be proud to stage, and the pale yellow Yvonne Cayeaux is very distinctive and choice.

Lupins may be used to good purpose, but there is the one tantalising trick they have of curling or twisting their spikes until they appear to have been tortured. I have experimented with the flowers to discover means of preventing this failing, and the best success has followed cutting in the very early morning, the day before the show, rolling each spike in a sheet of paper, left open at the top, and standing them, erect, in vessels of water in a shed, directly under a glass skylight. In this position the spikes remained erect while they filled their stems with water, and thus they remained stiff so long as required. Spikes cut in the evening and laid dry, in boxes, invariably twist, and refuse to straighten out. There are dozens of Lupins, all good enough for keen competition, but half-a-dozen must suffice and one of these should be either Delight, or Firefly, the two richest reds in the family. Gold Crest, Dresden China, C. M. Prichard, Joy, and Pink Pearls complete the half-dozen. I do not assert that these are the best six Lupins; indeed, it would not be difficult to select six half-dozens, but even then I believe one or two of those named would appear in almost every set.

Trollius play a useful part in June exhibits, and T. Ledebouri var. Golden Queen is particularly desirable; other good sorts being Triumph, Mrs. Harkness, and both Golden Globe and Orange Globe.

Delphiniums would present a baffling problem in regard to a selection of half-a-dozen varieties were it not for the fact that price will considerably simplify the task. It is only necessary to decide that half-a-guinea each shall be the minimum price with no limit to the maximum, and immediately Mrs. A. C. Kenrick, Mrs. Thos. Carlisle, Queen Mauve, etc., are written down; if on the contrary the limits are to be within half-a-crown and five shillings each, Nora Ferguson will doubtless be one, Mrs. A. J. Watson, Gen. Sir Douglas Haig, Lord Derby, an unhesitating choice for others, but no real enthusiast for Delphiniums will feel content without Millicent Blackmore and Rev. E. Lascelles, which latter is still one of the most distinct of Delphiniums.

July and August shows, and in the north, September as well, find Phloxes at their best, but he is a bold man who will cite a dozen varieties and say, "These are the best dozen Phloxes." It depends somewhat upon whether one is located in Scotland or somewhere round about London, for the ideal of the south is not the ideal of the north. At the London shows, and indeed throughout the South of England, the highly esteemed Phlox is one that produces a big, spreading truss, with very large pips of some striking colour, and such are largely found among varieties of Continental origin. The Scot, however, is keen on pyramidal spikes, built up as high as possible, with pips regularly placed, neither crowded nor gappy. The pip itself must be perfectly circular, flat, without a fold or kink in the petal to distort the perfect symmetry of the eye. A flower, no matter what its colour, which has a scalloped or uneven edge will not be tolerated, and that perfect regularity both in truss and pip is not always combined with great size. When it is, of course, the variety is the more highly prized, but form must stand first, even if a trifle of size is sacrificed as a consequence. I have no intention here, of discussing the question of which is the better ideal, but simply suggest that the English exhibitor will be well advised to make his selection from the biggest Phloxes he can get, but if he essays to take an exhibit to Scotland, then he must consider form first of all. Likewise the Scottish exhibitor who comes south will probably do better to consider size, even if he is inclined to shake his head and say "a wee bit coarse."

For the later summer and autumn shows, Kniphofias are a tower of strength. Mount Etna, Royal Standard, Torchlight Improved and K. aloides, Beecroft var. are extremely good among the giants, and of the lesser lights in point of size, Erecta, Coralina, Buttercup and Russell's Gold will serve one royally. The new hybrids of Lobelia syphilitica are great exhibition flowers, and the Sidalceas, of which there are now many beautiful varieties and hybrids, will be useful both in summer an autumn.

Another flower that will prove equal to filling a vase all through the show season is Salvia virgata var. nemorosa. It should, if possible, be staged in front of a sulphur or lemon-yellow colour, it being of very dark shades.

Scabiosa caucasica is invaluable, but it is useless nowadays to show flowers of a mediocre stock; it must be either an Isaac House variety or a specially good selection of the "perfecta" type. Nobody thinks of showing the old form of Erigeron speciosus now; Quakeress, Merstham Glory, or Asa Gray are chosen, while the Erigeron × Aster, Mesa Grande, is a capital vase flower.

It is undesirable, and quite unnecessary, to run near the border line of disqualification by showing subjects which open up dispute as to their eligibility in classes for hardy herbaceous flowers. Florists' Pentstemons, hardy Fuchsias, Spiraeas (not confusing these with Astilbes), and even Antirrhinums and Sweet Williams are best left out when there is the slightest fear that the wording of the schedule may be taken to exclude them.

In a final word, let me strongly urge that the aim of schedule compilers should be to make their meaning perfectly clear, and the aim of the exhibitor to put up a really good exhibit, to win or lose on its merits; not to creep in by straining after a disqualification of an opponent's exhibit, even though there may be a little evidence of licence in his interpretation of the wording in the schedule. Exhibiting should be a pleasurable, friendly warfare, free from cavil and bitterness. *A. J. Macself.*

NOTES FROM A WELSH GARDEN.

If it is still too early to realise the full extent of the injury done to tender and half-hardy plants during the November-December frosts, it is quite manifest that the casuality list would not have been nearly so serious has we experienced more normal weather during the preceding six months. When the frost came it found very many things with growths soft and sappy, perhaps still growing. But this was not so much the direct outcome of a warm, wet autumn as the effect of the latter following a long period of drought. During that rainless period, extending into the later summer, many subjects received such a check that one felt that an unusually vigorous and prolonged autumn growth was inevitable, and that is precisely what occurred.

In illustration of this it is interesting to note the following: Among a group of Leptospermums are several bushes of that fine variety, L. scoparium Chapmanii. One of these, probably because it did not flower so freely as the others, made a lot of new growth from August onwards, and it was still soft when frosty weather intervened. The result was that whilst its companions which had ripened their wood escaped without any injury, this particular individual had every shoot cut half-way back. The bark of these upper parts is now split and gaping, and every leaf is withered and brown.

More serious damage was inflicted upon small plants about the margin of the bog and in damp borders. In many instances these had their roots torn off by upheaval, and it was a curious, if vexing, sight to see precious Primulas and other plants raised on pillars of ice to as much as six inches above the surface. When thaw came and the soil resumed its old level most of the Butterworts (Pinguicula) were lying about the surface looking more like tiny Lily bulbs than anything else. Many of these had not a scrap of root left, and one wonders how they fare on the moors where frost is even keener, and where they often grow alone on bare soil. Doubtless many of the yellowy-green, scaly nodules would ultimately re-fix themselves in a congenial location and the question might be asked whether this disruption by nature has been adopted by the plant as a means towards dispersal? Stranger things have happened.

The winter-flowering Periwinkle (Vinca difformis) has been bright and cheerful since November in a sheltered nook in the woodland, a pure white form being especially striking. Though perhaps rather less hardy than V. major, the slight injury this plant suffers from frost is very soon overcome in our climate, for it is a vigorous grower and bloomer.

The most beautiful berry-bearing shrub throughout December has been Cotoneaster pannosa, and we can generally count upon this fine species retaining its fruit crop until well into February. But, quite apart from the rich crimson of those abundant and prettily-disposed clusters, which, by the way, are rarely touched by birds here, C. pannosa is a singularly charming shrub. The evergreen leaves, slightly silvered by silky hairs, the elegant poise of the beautifully tapered branches and the red-brown bark, together have an extremely handsome effect, placing this Chinese species among the very best of its kind. Another member of this genus which is always very attractive at this season is C. Henryana. Though it does not fruit with the freedom of many others, the large leaves, now a rich bronzy green, and the drooping, spreading habit never fail to receive admiration.

In leaf-colour, however, during the earlier months of winter, one gets the brightest tints in those subjects with gold or silver foliage. Here many of the Coniferae excel, and one need hardly point out how the colours of Cedrus atlantica glauca, the blue Spruces and the blue and gold Cypresses stand out in their fullest brilliance these winter days. The very beautiful Cupressus macrocarpa aurea is worthy of special mention, but the colour of even this fine subject cannot exceed the gleaming gold of that excellent little Scots Pine (Pinus silvestris aurea), which here occupies a place among some lichened rocks on an elevated part of the rock garden. The Junipers are also at their best just now, especially those of a glaucous or golden hue.

In the same way many of the Oleasters (Eleagnus) are admirable winter subjects. E. macrophylla is particularly good, and this splendid shrub has carried its fragrant, Fuchsia-like, silvery blossoms throughout the hard weather. Arbutus Menziesii, a specimen about fifteen feet in height, has borne for the first time here some clusters of its orange-coloured fruits, but if this charming Californian species never gave us any more than its large, glossy, bright green leaves and its cinnamon-brown bark it would rank among the choicest of ornamental evergreens. Bret Harte was not drawing very heavily on his imagination when he described the Madrona, as this Arbutus is known in California, as a gay woodland masquerader in Lincoln-green and scarlet hose!

Although the dwarfer Ericas have ceased to flower by the time E. darleyensis shows its first pink blossoms, there remains a great charm about a garden of hardy Heaths in winter. The various shades of green displayed by different species and varieties are in themselves very delightful, but this foliage is even more effective as a setting to the ruddy-browns of the faded inflorescences. Some of these latter are, indeed, a feature of the season which few can overlook, especially in Erica vagans and E. stricta, whose fuzzy twigs of bright moss-green terminate in calyx clusters of a warm foxy-red. It is in appreciation of colour of this description that we always allow the dead stems and flower heads of herbaceous Spiraeas and Astilbes of the waterside to remain standing so long as possible. A good, broad belt of these, glowing with a rich rusty-brown was quite a cheerful feature during the frosty spell. In a neighbour's garden I lately saw such an array against the fresh, yellow-flecked green of Bamboos and the effect was most impressive. *A. T. Johnson, Ro Wen, Talycafn, N. Wales.*

PUBLIC PARKS AND GARDENS.

The Swansea Corporation has recently decided to acquire half-an-acre of land adjoining Cwmdonkin Park, at a cost of £900 in order to prevent building, and to preserve the charm of this park, which is considered the finest of all the many parks and open spaces in Swansea. The Council has further agreed to promote a Provisional Order for the purchase of twenty acres of the Ravenhill Estate for the purpose of an ornamental park. It has also been agreed to purchase the Hafod Fields, consisting of seven acres and an area of twelve acres at Llansamlet, both for developing into recreation grounds.

The City of Liverpool has received a generous and beautiful New Year's gift from the six sons of the late Mr. and Mrs. Thomas Clarke. This gift, consisting of Allerton Hall and the surrounding Allerton Park, about forty-three acres in extent, is presented by the sons in memory of their parents. The Clarke family has a long history and for many years has been associated with the tobacco-manufacturing industry in Liverpool. The Corporation proposes to use Allerton Hall as a branch library and art gallery, and the park for public pleasure grounds and sports. Liverpool has a number of large public parks and open spaces, the biggest of which is Sefton Park, with an area of 269 acres. Newsham Park, with 147 acres and Wavertree Park, with 108 acres are others of importance.

PLANTS NEW OR NOTEWORTHY.

PRUNUS SERRULATA VAR. FUDAN ZAKURA.

Perhaps one of the most interesting introductions is a Cherry called Fudan Zakura, belonging to the "serrulata" group of Japanese flowering Cherries. Its native name signifies "Continuous Cherry," and has apparently been given to it on account of the long period during which it remains in bloom. This plant blossomed with me for the first time in the spring of 1925, when it opened its first flowers early in March. Flowers were then produced uninterruptedly for six weeks, a curious feature being the gradual lengthening of the peduncle as the foliage appeared. Flower buds commenced to swell again in late autumn, and a few opened before the end of November, 1925. As with Prunus subhirtilla autumnalis, these were damaged, and further development retarded, by the severe weather; but a spray cut and put into a vase readily responded to the warmth of the house, and the blossoms opened fully (Fig 13). The flowers are pure white and measure about one inch to one-and-a-quarter inch in diameter. They are borne in close clusters against the naked wood, and are extremely decorative.

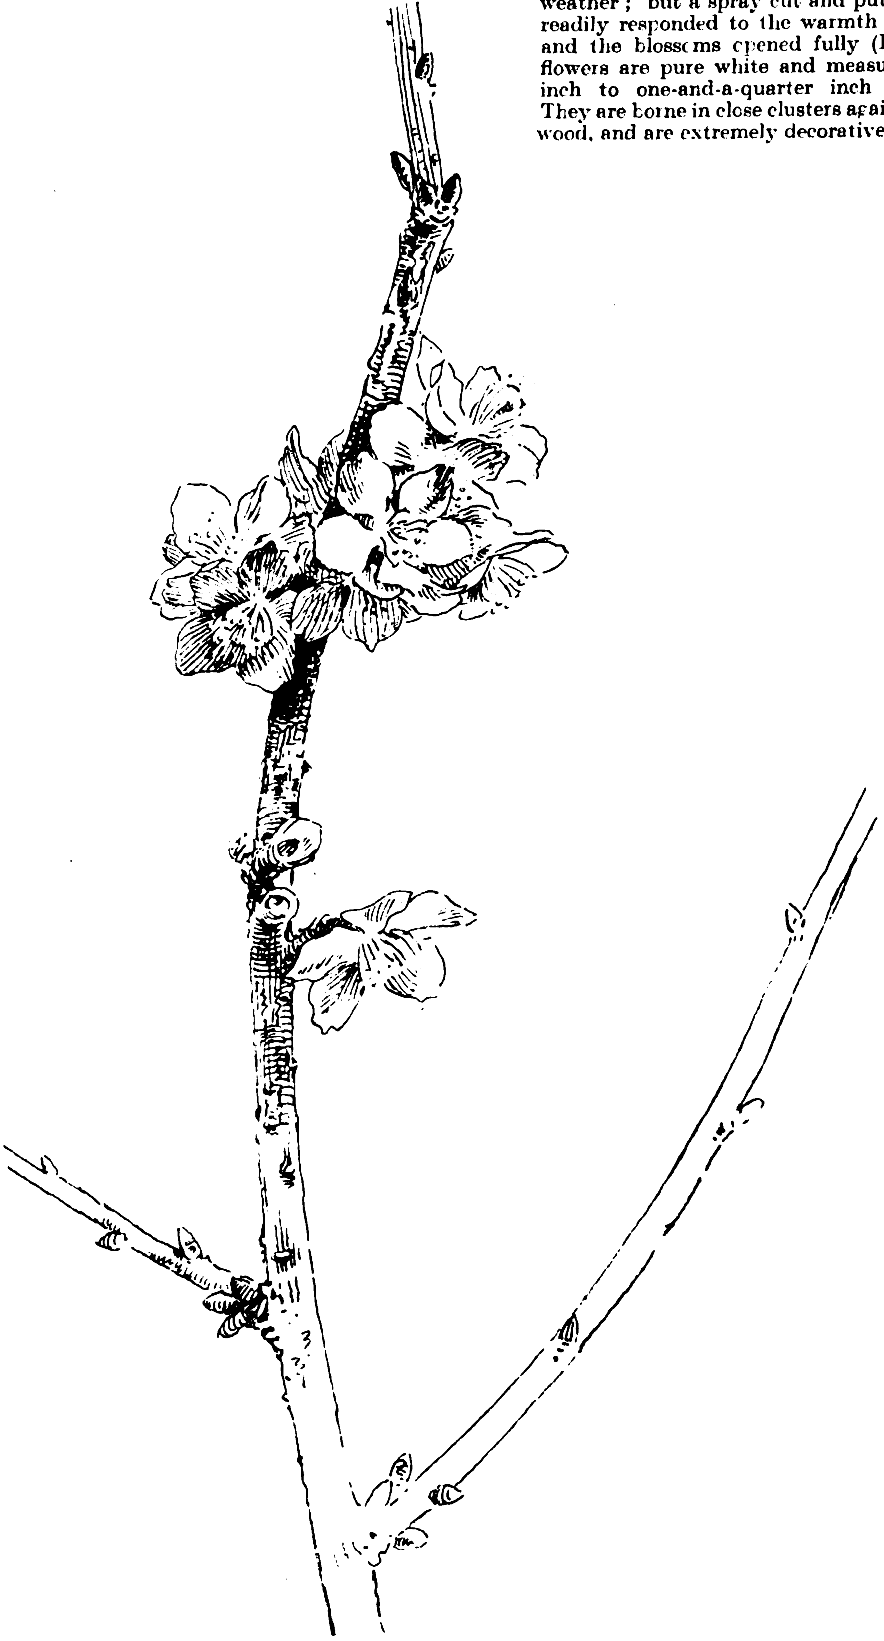

FIG. 13.—PRUNUS SERRULATA VAR. FUDAN ZAKURA.

This Cherry should prove a very valuable plant for forcing purposes. It is surprising that the variety has never been introduced before, for, so far as I am aware, my plants are the only ones existing in Europe. *Collingwood Ingram, The Grange, Benenden.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.

Urgent Communications.—*If sent by telegraph, these should be addressed "Gard. Chron.," Rand; or by telephone, to Gerrard, 1543.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

STERCULIACEOUS PLANTS IN SOUTHERN GARDENS.

THE family of the Sterculiaceae is not abundantly represented in gardens. Most of the members are not hardy enough to be grown out-of-doors. The only representatives frequently met with are Fremontia californica, a shrub or small tree with showy yellow flowers, from California, and a stately tree, Sterculia (or Firmiana) platanifolia, from China. Both are, however, rather tender, and only succeed in very sheltered positions. Whilst the Fremontia is not rare in English gardens, I have never met with it in Italian gardens, where, on the contrary, fine trees of the Sterculia are frequently seen, especially in northern Italy. Both are deciduous. The finest representatives of this interesting, chiefly tropical and sub-tropical family, are evergreen, and form a conspicuous feature in the gardens of the Mediterranean.

It is especially the genus Brachychiton that adorns the gardens and avenues of this region. This genus is composed of about eleven species and confined to Australia. Of these, only four species are found in cultivation, and only two of them again are planted to a great extent. The commonest of all is Brachychiton populneum, R. Br., which forms a tall tree forty feet to fifty feet high or more, with a straight trunk and smooth, greyish-green bark. The branches are directed upward, so that they form an erect, pyramidal crown. The leaves are variously shaped. On young plants they are deeply five-lobed, the two basal lobes small, the others linear and acute. On about three-year-old individuals, which may be four to five feet high, the leaves are broader, and these only have three broad lobes. On adult trees the leaves become ovate-lanceolate, pointed, almost resembling those of the Poplar. The foliage is always long-stalked, firm and glossy-green above, giving to the trees an attractive appearance all the year round. In early summer, —June and July, the trees flower abundantly. Every branch terminates in a panicle, carrying a fairly good number of graceful, bell-shaped, five-lobed flowers, each about half-an-inch long. Although they are not vividly coloured, being whitish, spotted with fine wine-red dots inside, they brighten up the trees considerably; the flowers are followed by a number of large, oblong, woody pods. These open on one side and expose a honeycomb structure containing a number of black seeds of the size of small Peas.

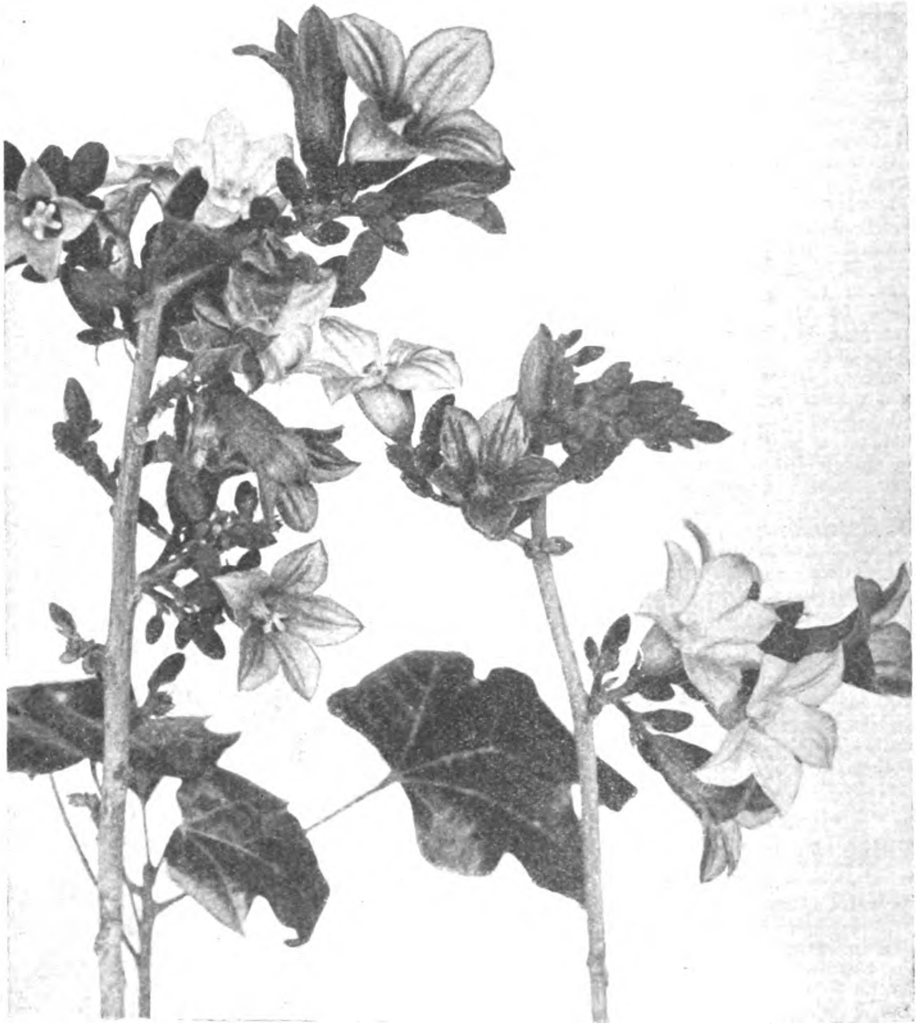

FIG. 14.—BRACHYCHITON BIDWILLII.

Brachychiton populneum occurs from Queensland to Victoria and is also found in Western Australia. It seems to have been introduced in 1824, according to a note in *Nicholson's Dictionary of Gardening*, under Brachychiton diversifolium, which is a synonym. [The *Index Kewensis* refers the Brachychitons to Sterculia. Eds.] I do not know when the tree first came to Italy. By now they are established all along the Mediterranean since at least forty to fifty years. As these trees grow very quickly and flower and fruit profusely, they evidently spread in a comparatively short time. They form excellent avenue trees with their pyramidal crowns, and succeed in every ordinary soil that is deep enough to provide the roots with sufficient moisture, especially during summer. Their wood, however, is soft and of little value.

Less frequently one sees Brachychiton acerifolium, F. Muell., from New South Wales. It is a much nobler tree than the former. Its comparative rarity may be due to the fact that it does not produce annually an equally large crop of seeds. Yet when seeds are produced, there is ample opportunity provided for its propagation. It is equally quick growing, but reaches a greater height, forms a tall, greenish stem and a broadly pyramidal crown. The leaf stalks are about five to eight inches long, the blades coriaceous and glossy green on both sides, about eight inches across, divided almost to the base into five to seven pointed lobes. In young individuals these divisions have again one or two acute lobes on each side. Whilst Brachychiton populneum starts flowering early in life and does so every year, Brachychiton acerifolium, on the contrary, only flowers when adult or when of a certain age, and then but rarely. Years and years may pass and the tree never shows a sign of a flower, but suddenly it seems to change its mind, and to gather all its energy to make up for the lost time, and the whole tree is then literally covered with flowers. At that time, many, if not most of the leaves, are shed. The tree then presents a marvellous aspect, and when seen unawares from some distance, one has the impression of a huge flame, and one finds the native name "Flame-tree" most appropriate. It flowers usually in midsummer—July and August. The Flame-tree is certainly one of the finest trees for the south. It should be planted far more frequently, but it demands a good soil and a little more sheltered position than the now almost ubiquitous Brachychiton populneum. *Nicholson's Dictionary* gives no data for the time of its introduction.

A much smaller tree, or rather only a large shrub with a short trunk and spreading branches, is the third species, Brachychiton Bidwillii, Hook (Fig. 14). It is a native of Queensland, where it was first discovered by Bidwill in the Wide-Bay district, who also sent seeds to Kew in 1851. It grows much less regularly than the two former species, which, besides, are entirely glabrous, whilst the young shoots and most parts of B. Bidwillii are densely hairy. The leaves are mostly three-lobed, but sometimes also five-lobed, rather thick, soft, dark and dull green above, and brownish, stellately tomentose underneath. It starts flowering as a rather young bush, and once started it continues flowering every summer. Indeed, it is one of the most showy summer-flowering trees of its region. The flowers are borne in short-stalked clusters from the axils of the upper leaves, often so many as twelve to fifteen together. They are bell-shaped, one-and-a-quarter inch long, with five spreading, deltoid lobes, of a fine crimson-red, and stellately tomentose outside. The flowers follow in continual succession from the same panicle throughout the summer. They are followed by the characteristic pods, containing a fair number of good seeds. It succeeds in every good garden soil, and the latter does not need to be irrigated, at least, along the Riviera. The shrubs do not exceed twelve feet, and on account of their irregular growth are best adapted for the shrubbery.

The fourth species, Brachychiton rupestris, K. Schum., may be considered a rarity in the gardens of the Mediterranean, and perhaps will always remain so. It is a native of Queensland, and must have been introduced in the later seventieth of last century. Nicholson, under the name of Sterculia rupestris, Lindl., gives a later date for its introduction. He states that it forms a good-sized greenhouse tree. That may be so, but in the open, as I saw it, it is of very slow growth, scarcely making any noticeable progress for ten or twelve years, and not exceeding four to five feet. It forms a thick, smooth trunk, which is quite soft and full of juice. It is said to be eaten by the natives. On account of this thick trunk it resembles the Bombax, and like these it is called the "Bottle Tree" by the colonists. Already, as a young plant, it shows a tendency to form a pyramidal crown, and the branches are more or less verticillate. It is smooth throughout, like the two first species. The leaves are cut into five or more narrow lobes, three to six inches long, but become entire, oblong-linear or lanceolate in age. I have never seen a flowering specimen.

Of the genus Sterculia itself, several species have been tried, but they are too tender for most parts of the Mediterranean region.

Another genus of this family valuable for the gardens of the sunny south is Dombeya. The most gorgeous species of this genus, however, D. Wallichii, Benth. and Hook. (or Astrapaea Wallichii, Lindl.), a very large-leaved tree from Madagascar, is, unfortunately, too tender for most Italian gardens. It never attains its normal size, and is frequently damaged by cold. Nevertheless, it sometimes flowers in spring. It must have a very sheltered place as protection against wind and frost.

A fine substitute for this gorgeous and tender tree was raised by a skilful French gardener, M. Cayeux, and named after him by M. Ed. André Dombeya Cayeuxii. Although not so big as D. Wallichii, it is perhaps finer and more graceful; it has the same habit, and its flowers are of a very pleasant colour. What is most essential, it is decidedly hardier. It is a tall shrub, hispid on the young parts. The petioles are four to six inches long, thickened at the base with two deltoid stipules. The leaves are roundish-cordate, more or less three-lobed, long-pointed, coarsely but sharply toothed, bright green, soft in texture, thirteen inches long and almost as wide. The peduncles are axillary, and drooping, about as thick as a pencil and reach six to nine inches in length. The flowers develop in a globose cyme, four to six inches across, composed of thirty to thirty five flowers, subtended by three to four convex bracts. Each individual flower is rotate, one-and-a-half inch across, Mallow-shaped, and of a lovely pale rose colour.

The plant is of vigorous growth and abundantly floriferous. Each leaf axil sends out a flower stalk. Flowers appear from Christmas till March in continual succession. It is evident that this plant must have a very sheltered spot if it is to flower and to display all its beauty during winter. It requires a good substantial soil and plenty of moisture when growing. Before it starts new growth, about June, it should be pruned back, otherwise the branches become too long and too weak. Doubtless it is one of the finest plants that the Mediterranean gardens can boast of, and should be grown wherever it is possible. It is easily propagated by cuttings taken from young side shoots.

Other Dombeyas which can be grown on the Mediterranean are shrubs like D. Burgessiae, Harv., from Natal, which in habit resembles Sparmannia africana; Dombeya Mastersii, Hook. fil., from Abyssinia, with pretty rose-coloured flowers, and a few others. However, none can compete with D. Cayeuxii, all have smaller flowers and are not nearly as ornamental.

All the other Sterculiaeceae found in gardens are shrubs. The rare Melhania Erythroxylon, R. Br., the "Red-wood" and M. Melanoxylon, Ait. (Fig. 15) the "Black-wood," both natives of St. Helena, succeed well on the shores of the Mediterranean, but apart from their botanical interest they are of no great importance as ornamental plants. Both species are said to be almost extinct on their native island and it is chiefly for that reason that they should be preserved in gardens, since they grow easily and may be increased by cuttings.

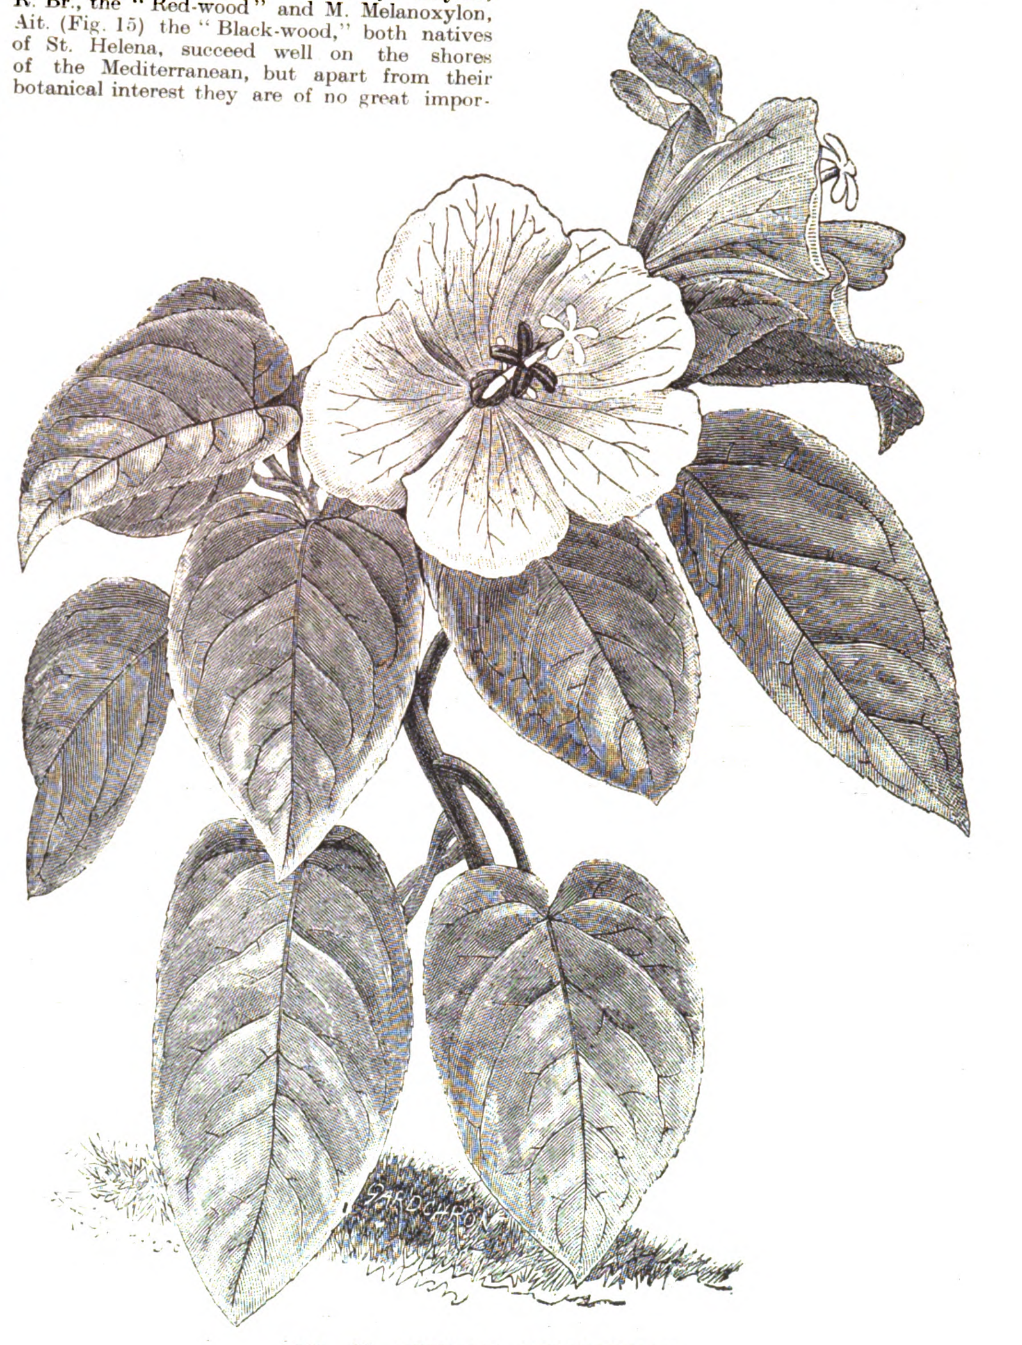

FIG. 15.—MELHANIA MELANOXYLON.

A few species of the vast genus Hermannia have always been favourites in gardens. They are South African, mostly small shrubs, with pretty little bell-shaped flowers in racemes, varying from yellow to red or purple. They are useful for bordering shrubberies, for rockeries or dry walls, and withstand the summer drought and the winters exceedingly well. It would be worth while to introduce a larger number of species, since they may be raised easily from seeds.

There are several other genera of this family occasionally found, such as Buettneria, Rulingia, Guichenotia, Thomasia, etc., all with curiously shaped small flowers, but of no great ornamental value, and only of interest to amateurs.

One larger shrub, however, deserves special mention: Reevesia thrysoidea, Lindl., named after the late John Reeves, an English resident of Canton, who introduced several beautiful plants from China. It is a pretty evergreen shrub, five to eight feet high, with alternate, ovate-oblong, pointed, dark green leaves two to five inches long. The creamy white flowers, though individually small, develop in flat, corymbose panicles, three to four inches across. They appear from May to June and are very attractive. It is a fine and interesting shrub for a sheltered, half-shady place. If too much exposed to scorching sun the foliage is apt to turn yellowish-green. It needs plenty of water during its growing period, and a soil not excessively heavy. Wherever it is grown to perfection it will form a most cherished shrub. It is propagated by marcotts [layers] or by cuttings of half-ripened wood under glass. Another species, R. pubescens, Mast., was introduced later. It has larger leaves, which are brownish tomentose underneath. The flowers also are a little larger and pink.

Pterospermum acerifolium, Willd., from India, is occasionally found in gardens along the Riviera. Although it never reaches any considerable size, it forms a useful and interesting shrub for shady and somewhat damp places. Its large, roundish leaves make it quite ornamental but I have never seen it in flower. The whole plant, at least, its young growth, is covered with a stellate tomentum.

The finest representative of the whole family is scarcely ever seen in Mediterranean gardens. I only know of one young promising specimen grown from native seeds, which did quite well. It is Cheirostemon platanoides (syn. Chiranthodendron platanoides, Baillon), the famous "Hand Tree" (*Bot. Mag.*, t. 5135). It is a large, stately tree, densely covered in all its young parts with a ferruginous felt of stellate hairs, and with large, deeply seven-lobed leaves, green above, yellowish or whitish on the back. The flowers are borne singly, and are very showy, their large, fleshy, purplish, or blood-red calyx, and the five widely protruding vividly red anthers, resembling the fingers of a hand or the claw of some animal. When Cortez conquered Mexico a specimen of this famous tree was found growing in Montezuma's garden. It was long believed to be the only existing plant, and superstitious tales of the natives were recorded. Alexander von Humboldt found it in forests about Oaxaca in Southern Mexico. It ought to be tried in the warmer parts of the Mediterranean region; it does not seem particular as to soil. Where it can be grown successfully it is sure to become one of the most valuable trees of the garden on account of its very ornamental foliage and wonderful flowers. *Alwin Berger.*

MESEMBRYANTHEMUM.

(Continued from p. 13).

51c.—C. exsertum, N. E. Br.—Stemless. Growths 1-1¾ inch high, 6 - 9 lines broad, and 5-6 lines thick, somewhat cuneately cylindric below, compressed, and two-lobed at the top (type S); lobes 2-4 lines long, slightly diverging, flat on the inner face, rounded on the back, obscurely keeled on the top, obtusely rounded at the top in side view; surface smooth and slightly harsh to the touch, glabrous, pale glaucous-green or whitish green, with a small patch of darker green at the base of the notch between the lobes, and numerous small dots of darker green scattered all over the surface, but less thickly on the lobes, and with the keel on the top of the lobes red. Flower rising far above the top of the lobes of the plant. Ovary entirely exserted. Calyx 4-5-lobed, whitish or with reddish tips to the lobes; tube 2-2½ lines long; lobes 1-1½ line long, oblong, obtuse. Corolla about an inch in diameter, expanding in the afternoon, scented; tube 6-7 lines long, much longer than the calyx, funnel-shaped, yellow; petals 5-6 lines long, ½ line broad, linear, acute or obtuse, recurved-spreading, entirely clear yellow, shining. Stamens numerous, in 4-5 series, all arising below the middle and the lower at the bottom of the tube, with the upper exserted; filaments orange; anthers yellow. Style 5 lines long; stigmas about 2½ lines long, filiform, slightly spreading, entirely exceeding the anthers, deep orange-red. Top of the ovary conical, green.

Little Namaqualand: Locality unknown, sent to Kew with other species by Professor Pearson in 1911.

This species might easily be mistaken for C. albescens when seen separately, but may be recognised by the lobes of the plant being flat (not convex) on the inner or notch side, by the surface of the plant being destitute of the microscopic points that cover C. albescens, and by the flowers also being different, the stamens being only just exserted and much overtopped by the stigmas, which are also of a darker red.

50a.—C. hahlenbergense, N. E. Br.—Growths described and figured as being 4-12 lines high and 3½-8 lines broad, but in the plants seen 3-7 lines high, 3-4 lines broad a 2-3 lines thick, compressed, cuneately obovoid, shortly 2-lobed at the top (type R); lobes erect, less than 1 line long and rounded on the inner face in the plants seen, but figured as being 2-3 lines long, slightly keeled along the top, which is rounded in side view; surface smooth, microscopically puberulous, slightly velvety to the touch, green or somewhat glaucous-green, distinctly dotted with darker green, often tinted with purple at the apex under full exposure to the sun. Flowers small, figured as being about 3 lines in diameter, yellow. Capsule when closed 1¼ line in diameter, when expanded 3½ lines in diameter, 4-celled, seeds few.—Mesemb. hahlenbergense, Dinter in *Fedde Repert., Beihefte* (*Succulentenforschung in Sudwest Afrika*), v. 23, p. 62 (1923); and Dinter and Schwantes in *Zeitschr. f. Sukk.* v. 2, p. 17 (1925).

Great Namaqualand: Near Hahlenberg Railway Station, in the region of Angra Pequena, Dinter 3746!

56a.—C. Roodiae, N. E. Br.—Growths of imported plant 5-6 lines high, 3-4½ lines broad and 1½-2½ lines thick, becoming under cultivation 5-16 lines high, 4-7 lines broad and 2½-3½ lines thick, compressed obconic-oblong, unequally or occasionally subequally 2-lobed at the top, with the notch ¾-3 lines deep (intermediate between types S and T); the lobes are subcontiguous, subterete and very convex or rounded on the top, and the orifice between them about 1 line long; surface smooth, glabrous, of a light green, or somewhat yellowish-green at times, not at all glaucous nor grey-green, usually with a few indistinct darker green dots that are pellucid when held against the light scattered over each lobe, but sometimes nearly or quite dotless. Calyx-tube 1½-2 lines long, partly exerted from the orifice, lobes 1¼-1½ line long, oblong, obtuse, pale greenish (but perhaps reddish under strong sunlight). Corolla 5-8 lines in diameter, expanding in the daytime; tube about 2 lines long, scarcely longer than the calyx-tube; petals in about 2 series, some 4 lines long, and ¾ line broad, linear, obtuse, pure white on both sides. Stamens in two series, one series arising from the base of the corolla and finally exserted from its tube, with the longer filaments about 3 lines long, pale yellowish; anthers light yellow. Glands in a circle around the top of the ovary, dark green. Stigmas 4, free, no style, finally about 4½-5 lines long, filiform, as long as or exceeding the stamens.

Van Rhynsdorp Division: near Van Rhynsdorp, Mrs. E. Rood.

This is a very distinct species, distinguished from all others at present known by its form, unequally lobed top, rather soft substance, light green colour and white flowers, which expand in the daytime. It is one of the very few in the genus that have no style.

Of this species I have seen only one plant, which had the appearance of having grown in the crevice of a rock. I believe it to be rare, and have great pleasure in naming it after its discoverer, to whom I am indebted for several interesting plants.

53a.—C. sororium, N. E. Br.—Stemless or with age forming short underground stems. Growths 1-1¾ inch high, 6-9 lines broad and 4-8 lines thick, cuneately cylindric or oblong, compressed and 2-lobed at the top (type S); lobes 3-6 lines long, often diverging, flat on the inner face, keeled on the back, somewhat obliquely acute or subacute in side view where the inner face and keel meet; surface smooth, glabrous, of a somewhat dull glaucous-green, with a small patch at the base of the notch and numerous small dots sprinkled all over it, all of a darker green, and when exposed to full sunshine the edges and keel of the lobes become red. Flower not rising above and usually well below the level of the top of the lobes. Ovary always included in the body of the plant. Calyx 4-lobed, more or less exserted; tube 2-2½ lines long, pale greenish; lobes about 1-1½ lines long, oblong, obtuse, whitish or pale greenish. Corolla 8-11 lines in diameter, expanding in the afternoon, not funnel-shaped; tube 2½-3 lines long, pallid; petals 45-53, in 2-3 series, about 5 lines long, and ⅓-¼ line broad, linear, obtuse, widely spreading, with recurved tips, bright light yellow on both sides, shining. Stamens numerous in about 3 series, anthers all at or shortly exserted from the mouth of the corolla-tube, pale yellowish. Style 3-4 lines long; stigmas 5, filiform, 2½ lines long and exserted above the anthers for all their length, slightly spreading, pale yellowish.

Little Namaqualand: probably from between Stinkfontein and Chubiessis, as it was sent by Professor Pearson along with C. bilobum. *N. E. Brown.*

(To be continued.)

INDOOR PLANTS.

DRACAENA.

WHILE the majority of the Liliaceae are remarkable for the beauty of their flowers, the genus Dracaena is an exception, being cultivated for its decorative value as an ornamental foliage subject. Despite the number of varieties of hybrid origin the old species hold their own.

Of the several distinct garden types, one of the best is D. fragrans var. Victoria (Fig. 16), a handsome plant when well grown, the leaves being yellow, with a broad median band of green. It is slow in growth, but retains its foliage and bright colour for several years. When the plants become leggy they may be ringed by making an incision in the stem below the lowest leaves and tying Sphagnum-moss about this part. The moss should be kept moist until roots appear, when the top should be removed and potted. Portions over two feet long may be successfully rooted by this method. After the removal of the top the stem will break into growth, and the resultant shoot, when a few inches long, may be inserted as a cutting, using screened Sphagnum-moss and sand as a rooting-medium. D. f. Victoria, in common with other members of the genus, requires a warm, moist atmosphere during its season of active growth, but in winter, a low temperature with an excess of moisture will cause the edge of the leaves to decay.

D. Sanderiana, a slender-stemmed species, with white and green leaves, is a fine subject for the plant stove. When established, it throws from the base long reed-like growths feathered with foliage. Cuttings formed of the young shoots root readily, and at the subsequent potting several plants should be placed in the same receptacle.

In general appearance, D. Godseffiana differs considerably from its congeners. The wiry, much-branched stems are clothed with whorls of variegated leaves, the creamy-yellow spots almost covering the whole surface of the leaf. Bushy plants may be grown in small pots, and make an effective edging.

D. Goldieana was introduced over half-a-century ago; it is one of the most handsome members of the genus, with closely-set, wide leaves, transversely banded with green and grey stripes. The stem is light, smooth and highly polished.

ERANTHEMUM PULCHELLUM.

FLOWERING in midwinter, when blue flowers are especially welcome, this Acanthaceous shrub is worthy of more extended cultivation. It forms a rounded bush, about two feet high, spangled with bright blue flowers, borne in the axils of green and white bracts.

Strong heat and plenty of moisture are essential for its successful cultivation, with drier conditions during the flowering period. After flowering, yearling plants may be cut back, shaken out, repotted, and grown on for a second season. Two-year-old plants usually give the best results.

CROSSANDRA UNDULAEFOLIA.

THIS summer-flowering member of the Acanthaceae is remarkable for the uncommon colour and quaint shape of the flowers. The flat, one-sided, five-cleft blooms are of a luminous salmon colour, and spring from the corners of an angular inflorescence.

The terete stems are clothed with whorls of glabrous, deep green leaves, which shine with an enamel-like gloss.

It is an erect-growing stove plant, from one foot to three feet high.

SANCHEZIA NOBILIS GLAUCOPHYLLA.

THE flowers of this plant are somewhat dingy in appearance, and are usually removed when in bud. It is a free-growing shrub-like plant, with lanceolate leaves nine inches long, glaucous green, with the mid-rib and veins margined with yellowish white; with age, or if too densely shaded, the foliage reverts to a uniform green, losing much of its attractiveness. It is one of the most easily cultivated of stove plants, and is propagated readily from cuttings inserted at any season of the year. This Sanchezia is a useful decorative subject, particularly in a non-flowering, young state. Several plants should be placed in one receptacle. If potted on, or planted out, it eventually forms a bush several feet high. *Fred. W. Jeffery.*

SEDUMS IN WINTER.

AMONG the more tender Sedums which have come through 16° to 18° of frost without injury is the shrubby S. prealtum. Several plants in pots of this species, put on one side and forgotten, were entirely unprotected, yet they are as fresh to-day as ever they were.

S. retusum, another sub-shrubby Mexican species, growing under similar conditions, has been rather badly cut back, but a worse fate has befallen that fine species, S. compressum, all plants being killed, even though protected by evergreen branches. S. Palmeri, however, has fared much better, most of the specimens being little the worse. Of the two last-mentioned, the latter is always the more striking as a foliage plant, especially at this season, when the leafage is a beautifully soft and glaucous emerald. The curious S. Stahlii is also among the survivors, though it often loses a good many of its curious, egg-shaped leaves at this season, and those that remain assume the dull colour of those of S. oreganum.

S. divergens makes a pleasing carpet of bright green, but here it does not take on the red flush which renders it so delightful in some gardens. On the contrary, that good all-round species, S. spathulifolium, is now a wonderful colour, the rosettes, two to three inches across, being a vivid red, paling to dove-purple at the centre. What form it is which affords this striking departure from the S. spathulifolium one usually sees in gardens I do not know. The leaves are distinctly redder, even in summer, than those of the type or the variety purpureum, and the rosettes are, as stated, unusually large.

The glaucous hue of S. hispanicum and S. dasyphyllum is always in evidence at this season, and S. Lydium, also a familiar, mat-forming species, associates well with them, for it still retains its late-summer crimson.

But in leaf-colour, few can compare with the little S. brevifolium, whose deep red, almost globular leaves, in four rows, are set in a blue-white mealiness of almost luminous brilliance. This tiny species is quite hardy here, and once it is established in the chink of a mossy or lichenous rock facing south it will soon form a colony, the little cast-off leaves taking root wherever they can find lodgment. The form of S. brevifolium I have here came under the name, "var. Pottsii," but I see that Dr. Lloyd Praeger does not recognise this as distinct. There appear to be many forms of this species, varying in size and other respects. *J.*

GARDEN TOOLS.

(*Concluded from page* 13).

IT is surprising how large a number of tools is necessary for the economic working of even a comparatively small garden. For ground work a spade, shovel, digging fork and manure fork are essential; the need for a pickaxe, a mattock and a crowbar often arises, and in the modern garden some kind of earth-borer to prepare holes for pergola standards, rose-poles, etc., is frequently required; while rakes hoes and cultivators of various patterns and sizes cannot be done without. Where new, undrained lands have to be brought under cultivation special draining tools are necessary. For planting, trowels, hand-forks and dibbers of good quality should be provided; a line and reel is a distinct advantage, and where bulbs are grown in quantity, a bulb planter is useful.

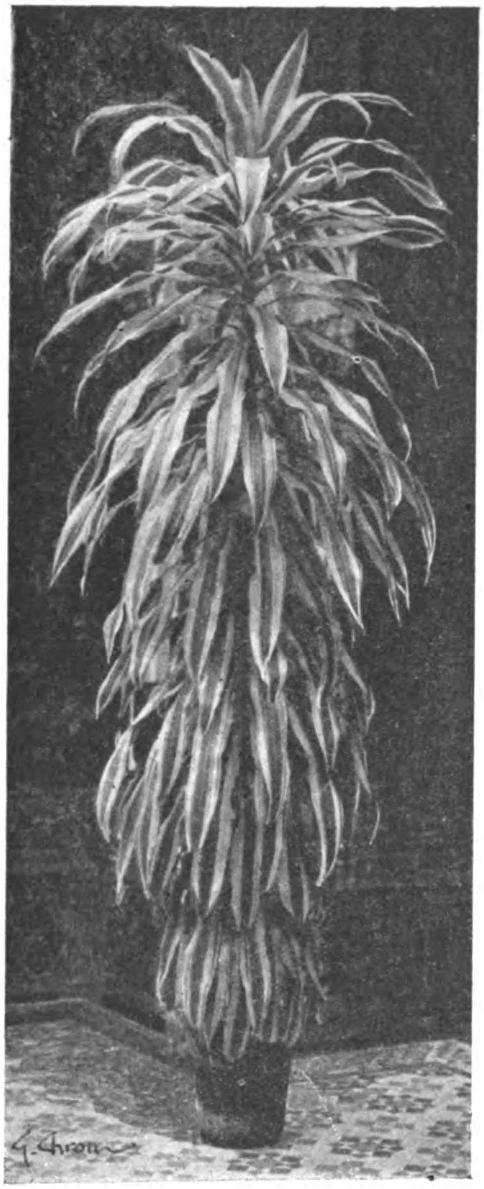

FIG. 16.—DRACAENA FRAGRANS VAR. VICTORIA.
(see p. 30).

Cutting and pruning tools form an important group, of which knives, secateurs and saws should be provided in at least two sizes. A branch pruner on a long handle saves a good deal of step work, and a Myticuttah is a very useful implement for close work. I know no ideal secateur, but a good parrot-bill pattern with double cutting blades is useful. A small hand-saw with short, curved blade, is a very useful implement, tackling awkwardly-placed branches with comparative ease. A small axe, or handbill, is desirable for pointing stakes, and where hedges exist, good, strong hedge-clipping shears will be necessary, while for topiary work nothing can beat small shears of the sheep-shearing type.

For transport of material in the garden, a wheel-barrow of moderate size is needed. This should be strongly made with a broad wheel, and be provided with a moveable top for the holding of leaves or other light material. In larger gardens, a combined hand-cart and plant truck is very useful, and a platform wagon on four wheels of narrow diameter is invaluable for moving heavy objects, such as trees, stone or metal figures and large vases. A swinging water-barrel, mounted on broad wheels, is always a great time-saver in conveying water,and where hoses are used strong reels for their convenient transport should be provided.

In connection with the distribution of water, water cans also play an important part, and influence the output of the man in a very high degree. They should be of convenient sizes to meet the nature of the distribution required, and for all-round, general purposes, it would be difficult to beat the Haws's pattern. A good syringe is indispensable if cleanliness is to be observed, and its timely use often obviates the need of sprays and sprayers. For small gardens, a spray syringe of the Abol type may be sufficient, but where large numbers of Roses and fruit trees are grown this will need to be supplemented by a knapsack sprayer or still larger sprayer of the engine type, while for large orchards, the modern power sprayer may be necessary.

Turf implements are expensive, but a good lawn is an essential feature of every garden, and it cannot be maintained without generous tool equipment. It is cheaper to have the best than to put up with inferior models. A well-built lawn mower, with ball-bearings, soon saves its cost in labour besides reducing the strain and upkeep cost of the machine. With the present cost of labour a motor mower, even for comparatively small gardens, is an economic proposition, and these have been so much improved in recent years that the ideal appears to be within sight. An attachment for carrying out surface cultivation during favourable weather in the winter season is very useful and time-saving. In this direction also a spiked turf-maul for puncturing the surface before the application of prepared top-dressings, and a scarifying whale-bone brush for spreading the compost after dressing, are extremely useful. An edging iron and a pair of edging shears are a necessity to keep the verges in good trim, and when turf is to be moved, a lifter and beater cannot well be done without. A garden roller is a necessity for lawns and other purposes, and the advantages of the water ballast type where a light or heavy implement can be had at pleasure, must be obvious to every-one. It is often difficult to do good work with a roller on newly-sown lawns, particularly those of small dimensions and a pair of treading boards strapped to the feet of the operator will be found preferable.

The scythe is almost a forgotten tool in these days—perhaps one ought to say that the scythesman is defunct—yet it is a tool that cannot easily be done without for cutting purposes. One should not be perturbed when the "old man" of the garden takes time in setting his scythe with such meticulous precision; it is an object lesson in the study of angles and although he would laugh at the word "science," he is really applying those scientific principles, the application of which is so necessary in setting the handles of tools generally to meet the need of the operator.

Screens and sieves have their uses in garden craft, and help in the grading of sand, ashes, gravel and soil for various purposes. The sieve is often a much abused implement of the potting-shed, in that it leads the young and inexperienced hand to spoil good materials by removing from them the fibrous and lumpy matter so essential to good potting composts.

In this general review of tools the list of useful appliances has by no means been exhausted. There are the Asparagus knife, fruit and flower gatherers, Daisy or Dandelion grubbers, slashers, Potato setters, grindstones and whetstones, subsoil tester, lawn sprinklers, fumigators, powder distributors, hammers, brooms and brushes, straight-edge, spirit levels, ground trammel, thermometers, leaf sweepers, baskets of various patterns and designs, vermin traps, steps and ladders, stoking tools, and a host of small tools of everyday use, all of which are necessary, but many of which serve more or less special purposes.

It will be seen from these remarks that the tool equipment of a garden is a matter of considerable expense, hence the conservation, care and preparation for use of them should be given serious thought. For the storing of tools of every description a dry shed is essential, and hanging positions should be provided wherever this is practicable. All implements with metal blades—and these constitute the majority of tools—should be thoroughly cleaned and oiled before being returned to their positions, and time allowed for this work greatly promotes tool efficiency. Lines, brooms, baskets or carrying sheets should never be put away wet, but hung outside till favourable drying conditions occur. On loamy soil, the edges of spades and hoes wear sharp, but on stony soil considerable sharpening is often necessary, and for this purpose a flat file, which can be carried in the pocket, is very useful. Pruning tools should always be kept with a keen edge for which nothing is better than a carborundum stone. The wheels of barrows and trucks should be regularly greased or undue wearing in important parts is bound to follow quickly, and an occasional coat of preservative to the bodies adds considerably to the life of the implements. Hoses should be thoroughly dried and rolled on to reels for storing, and syringes and sprayers should be rinsed with clear water after being used for insecticides, to prevent corrosion, while water cans should be stood upside-down to drain before being stored. In using mowing machines special care should be taken that all parts are adequately lubricated, and that the machines are thoroughly cleaned after use. *W. Auton.*

VALUE OF A GARDENER'S DIARY.

The advent of the New Year is an opportune time to present this subject to young gardeners.

When correctly compiled, a garden diary may be made both useful and interesting, and the facts contained in it may one day prove to be a source of valuable information to the author.

None should consider themselves so efficient that they can afford to neglect recording events and operations. Reliance upon the efforts of others in this respect, although sound in principle fails to give the maximum amount of information because the details would probably not be applicable to all districts and conditions.

Furthermore, once a fact is written down it is much more vividly impressed upon the mind of the writer.

A common mistake made by those who keep garden diaries is to make a note only of the work they actually perform themselves. A better method would be to make a point of finding out all the operations in progress throughout the garden. This could be accomplished either by an enquiry from the heads of the various departments, or, better still, by frequent tours of the garden where this is permitted. Probably this would prove rather difficult in very large establishments, but much can be gained by possessing the enquiring habit, provided it is of the right kind. A diary may be of the greatest assistance in future years, especially to those who are responsible for the maintainance of supplies of flowers, fruits and vegetables, and particularly for the timing of crops, so as to have them available for special functions, exhibitions, etc.

A diary is indispensable as a means of ascertaining the period occupied from the sowing of the seed to the maturing of the crop, and in some instances notes of the duration of the useful season would be advantageous.

The duration and time of flowering of the most popular hardy plants should be noted. This may seem a trivial matter, but a record of this may some day prove very valuable when arranging for a display for a particular occasion. The cultivators of such plants as Chrysanthemums and Carnations must find their diaries indispensable, as in these cases much depends upon records of the correct dates for propagation, "stopping" and disbudding.

The writers of weekly calendars for the gardening Press undoubtedly find their own previously well-kept diaries invaluable, as they contain actual facts which can be elaborated for the benefit of the less experienced.

A note should be made of the date of the first appearance of garden pests or diseases. This information should prove most useful in combating those troubles in future years. A knowledge of the time of attack enables the gardener to apply a preventive measure at the right moment, thus very often obviating the development of the disease or pest.

When the time comes to take charge of a garden weekly references to a diary will be of considerable help, and when once the additional notes of the first year's experience are completed, the task will be found much easier in succeeding seasons.

It would also reveal any slight mistakes in methods, such as sowing seeds too early, or too late, as the case may be, and these could be rectified in future years.

A note of any outstanding feature in the weather may prove interesting, such, for instance, as the effect of frost upon certain out-door plants, fruit trees, ornamental trees trees and shrubs, etc. It is surprising what a lot of useful information may be acquired by a study of meteorology.

A diary may also be made to record the cultivation of certain subjects in the most concise form. To illustrate my meaning take, for example, the cultivation of Peaches under glass. By keeping records of the temperatures at the different stages of development, together with the dates of starting the house, the flowering period, time for disbudding, the thinning of the crop, the duration of the stoning period, exposing the fruit to sunlight, fruit ripe, pruning and cleansing, etc., much useful knowledge is acquired.

Notes on the items to be recorded during the course of the year should include the dates of all such operations as seed-sowing, all forms of vegetative propagation, germination and flowering periods, the many stages of potting, planting and transplanting, the thinning of vegetable and fruit crops, stopping and disbudding: all forms of pruning, the protection and hardening off of plants, applications of manures and the various spray fluids and powders, etc.

In the actual compiling of a diary it is advisable to carry a small note book, or better still, the R.H.S. Diary, and make brief notes as they present themselves in the spaces set apart for each day.

The copying out of these notes in ink into a larger, permanent book capable of holding several years records may be done in leisure moments. *J. Wilson, Wisley.*

FORESTRY.

THE INFLUENCE OF PROLONGED DAYLIGHT IN THE VEGETATIVE SEASON ON THE QUALITY OF CONIFEROUS TIMBER GROWN AT HIGH LATITUDES.

Among woodworkers generally it has for long been known that the finest qualities of the European Coniferous timbers we import come from high latitudes. The timbers of the Scots Pine and Norway Spruce—the "redwood" and "whitewood" respectively of the North European timber trade—imported from the White Sea region of Russia have always had the reputation of being the finest qualities of their respective kinds in the market, and within comparatively recent years the timber of the Russian or Archangel Larch, which is probably merely a geographical form of the European species from practically the same region as the Scots Pine and Spruce, has established for itself a strong claim to recognition as a structural timber of the highest class.

The most familiar explanation of the superior quality of these North European timbers is that it is due to their being the produce of forests that have not been planted or tended by man—that is, of forests that have been self-sown and have grown and matured naturally. But the strongest argument against this view is that timber produced under similar circumstances at lower latitudes is not of equally fine quality.

We are well acquainted with the fact that plants vary more or less according to the altitude or latitude at which they occur, and that, as a general rule, increase in altitude or latitude brings nanism in its train. But ideas as to how climate is affected by altitude or latitude are sometimes very hazy. For example, in a comparatively recent work on horticulture it is stated that "altitude produces pretty much the same climatic conditions as latitude, i.e., roughly speaking, 600 feet rise at the equator ensures a climate somewhat similar to that found one degree of latitude from the equator, and so on." As regards some climatic elements, it is quite true that increase in altitude at low latitudes produces conditions which assimilate in some respects to those at sea level at higher latitudes; but when we consider the question of the variation in the length of the day at different latitudes, and the way in which sunshine is distributed over the globe at the various seasons in the course of the earth's revolution round the sun, the matter assumes a different aspect.

Were the rule given above followed out, at the equator it would require an elevation of over 14,000 feet to produce a climate similar to that at sea level at either of the tropics (23½° N. and S.), and of 54,000 feet (10¼ miles) to produce a climate similar to that at sea level at either of the poles. But a little reflection will show that at the equator the only effect which these enormous elevations would have upon the duration of the sunlight would be to increase by a very small amount the approximately equal daily instalments of it which the earth receives at sea level there all the year round, while at either pole a mountain peak would require to have an altitude of approximately 360 miles (over four times the height at which there is a sensible atmosphere) to catch a sunbeam at the winter solstice!

It will thus be seen that, however much increase of altitude at low latitudes may tend to assimilate some climatic elements to those at sea level at higher latitudes, as regards illumination by sunlight there is no analogy whatever between the conditions at great elevations at or near the equator and sea level at or near the poles.

It is only at the equinoxes that, for a very brief period, the daily duration of sunlight is the same over the whole of the earth's surface, and then the chemical intensity of the sun's rays varies according to latitude, being practically negligible at the poles and at its maximum at the equator. Within the tropics there is practically no seasonal interruption to plant growth throughout the year, but as we proceed to higher and higher latitudes, both north and south of the tropical zone, the interruption to growth becomes more and more pronounced, and the vegetative season is compressed into a shorter and shorter period until, at the northern and southern limits of plant life, it is restricted to but a few weeks.

Theoretically, there is, of course, a seasonal change within the tropics, and on the equator itself there are two "summer" and two "winter" seasons annually; but the difference between summer and winter anywhere within the tropics is so slight at sea level as to be almost negligible. *A. D. Richardson.*

(To be continued).

APPLES IN SURREY.

Surrey is not considered by pomologists to have great attractions as an Apple county, and the soil in the Woking district is certainly far from being of the substantial, loamy character usually regarded as essential for successful Apple culture. Nevertheless, the superb collection of one hundred varieties recently exhibited by F. C. Stoop, Esq., of West Hall (gr. Mr. G. Carpenter), was undoubtedly equal to any that the large growers of any county could have put up. I can imagine the astonishment of many Kent and Hereford growers on seeing so wonderful a collection from this district. Such an object lesson lends weight to the contention of many enthusiastic fruit growers, that there is room for a much wider development of Apple orchards throughout the country, as it offers ample evidence that good fruits may be grown on a wider range of soils than many experts imagine.

A few notes on the making and development of the orchard in which these Apples were grown may be of interest to readers of *The Gardeners' Chronicle*, and seeing that the underlying object of the planting scheme is to test the relative values of most of the varieties in cultivation at the present time, the plantation is of special interest to growers generally, and for those of Surrey districts in particular.

The site was part of an exposed, low-lying, undrained field of rough pasture, with a little shelter on the north and east, and the area planted is about two-and-a-half acres. The soil is somewhat heavier than is usual in the district, but it has no more depth than about eighteen inches, and overlies Bagshot sand. Draining was effected by opening a substantial ditch on two sides of the field, and laying two-inch drain-pipes across the field into the ditch. The preparation consisted in ploughing and subsoiling the field to a depth of about eighteen inches, and as no farmyard manure was available a surface dressing of accumulated leaf-soil and vegetable refuse was given.

Most of the trees were planted in the season 1919-20. They are all of the bush type, and worked on a good, dwarfing, Paradise stock: the varietal number of the stock is not available, however, as the trees are prior to the date of much of our present knowledge in this direction. Planting was simply carried out by digging holes of adequate size on the ploughed and subsoiled area, without any further preparation. The trees are planted in rows, twelve feet apart, the system of alternating positions in the rows being adopted. The knife was not used in the year of planting, except to remove bruised roots.

The total number of trees is 700 in 140 varieties. As time goes on the number of varieties will probably be reduced, as it is intended to weed out varieties of relatively little value, and regraft with others of proved merit. The plantation demonstrates the fact that private enterprise—from which horticulture has reaped such great benefits in the past—still exists. Valuable information is already being obtained, and the behaviour of many varieties, as time goes on, should prove highly interesting and instructive.

The routine cultivation in the plantation is carried out on up-to-date lines; the surface is kept clean by horse labour, so far as practicable, the spaces immediately around the trees being worked by hand. Spraying is systematically practised, and the trees are models of cleanliness.

In January and February the whole plantation is sprayed with Carbo-Krimp. Trees infested with scab are sprayed in April and again in May with Bordeaux mixture, and during the same months they are sprayed with lead-arsenate for leaf-eating caterpillars, while if aphides appear on individual trees they are immediately destroyed with a nicotine wash. From June onwards windfalls are systematically gathered up and destroyed by deep burial. If woolly aphis appears, affected parts of the trees are painted with methylated spirits. Grease-banding is done early in October, and cut surfaces made during winter pruning are dressed with Stockholm tar, this being an excellent preparation to prevent infection by spores of fungi.

Except for surface mulchings of decayed vegetable manure, no organic manures have been applied, but it has been the practice to dress the plantation every second year with basic slag, at the rate of 8 cwt. to 10 cwt. per acre. In the second and third years there was a sprinkling of fruits on many of the trees, and the crops have gradually increased, until in the past season something like 400 bushels were gathered, all of superb quality and appearance.

The following varieties were included in the gold medal collection:—Adam's Pearmain, Allen's Everlasting, Allington Pippin, Alfriston, American Mother, Annie Elizabeth, Arthur Turner, Autumn Pearmain, Barnack Beauty, Baumann's Reinette, Beauty of Kent, Belle de Boskoop, Ben's Red, Bismarck, Blenheim Pippin, Braddick's Nonpareil, Bramley's Seedling, Brownlee's Russet, Cox's Orange Pippin, Cox's Pomona, Cornish Aromatic, Cockle Pippin, Court Pendu Plat, Claygate Pearmain, Charles Ross, Crawley Beauty, Christmas Pearmain, Delicious, Duchess' Favourite, Duke of Devonshire, Dutch Mignonne, Ellison's Orange, Emperor Alexander, Encore, Fearn's Pippin, Foster's Seedling, Gascoyne's Scarlet, Gloria Mundi, Golden Noble, Golden Spire, Gravenstein, Hambling's Seedling, Hormead Pearmain, King Edward VII, King of the Pippins, King of Tomkin's County, James Grieve, Lady Henniker, Lane's Prince Albert, Lord Burghley, Lord Derby, Lord Hindlip, Loddington, Laxton's Superb, Margil, May Queen, Mère de Ménage, Monarch, Mrs. Phillimore, Newton Wonder, Norman's Pippin, Norfolk Beauty, Norfolk Beefing, Orlean's Reinette, Peasgood's Nonesuch, Rambour Papaleu, Rev. W. Wilks, Reinette Rouge Etoilée, Ribston Pippin, Ross Nonpareil, Royal Jubilee, Rosemary Russet, Rival, Roundway Magnum Bonum, Sandringham, Schoolmaster, Scarlet Nonpareil, Sir John Thorneycroft, Striped Beefing, Sturmer Pippin, Stirling Castle, St. Edmund's Russet, The Queen, The Old Nonesuch, Tom Putt, Tower of Glamis, Tyler's Kernel, Warner's King, Washington, Wealthy, Worcester Pearmain, Wormsley Pippin, Wellington, Wyken Pippin, William Crump, Comrade, Geo. Carpenter Victory and H. Shoesmith, the last four varieties being seedlings raised at West Hall.

The following twelve dessert varieties and twelve culinary varieties have, up to the present, been the most successful and persistent croppers: Dessert:—Allington Pippin, Charles Ross, Cox's Orange Pippin, American Mother, Duke of Devonshire, Ellison's Orange, James Grieve, King of the Pippins, Ribston Pippin, St. Edmund's Russet, Worcester Pearmain, Rival. Culinary:—Beauty of Kent, Annie Elizabeth, Cox's Pomona, Crawley Beauty, Bismarck, Edward VII, Golden Spire, Lane's Prince Albert, Lord Derby, Monarch, Rev. W. Wilks, Stirling Castle. This selection should be a valuable guide to growers in Surrey who intend planting Apple trees before spring arrives. *P. C.*

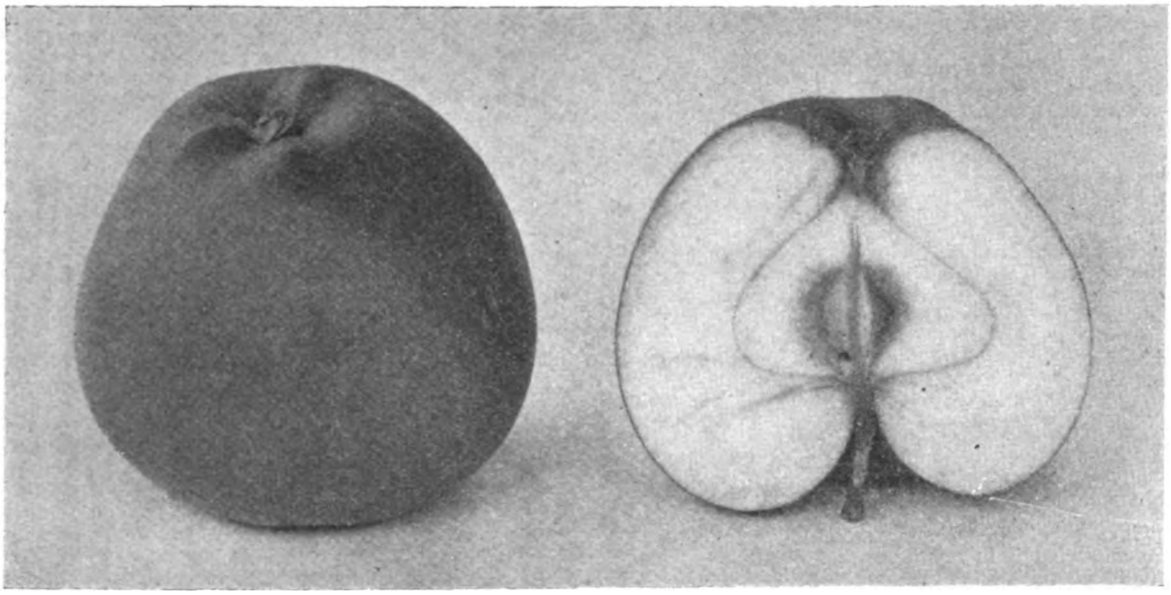

FIG. 17. APPLE STURMER PIPPIN.

(see page 34).

FRUIT REGISTER.

APPLE STURMER PIPPIN.

In a census of the best late Apples the variety Sturmer Pippin would be sure of a high place and probably come out top, for apart from its splendid flavour it is a general favourite with growers. Hogg states that it is one of the most valuable dessert Apples of its season. "It is of first rate excellence and exceptionally desirable both on account of its delicious flavour and arriving at perfection at a period when the several favourite varieties are past." This is indeed high praise, but fully deserved.

Now that the season of most Apples is over, that of Sturmer Pippin is scarcely yet reached, for it is at its best from February to June, so that it is one of the latest of dessert Apples.

It is said to have been raised from Ribston Pippin crossed with Nonpareil, by Mr. Dillistone, a nurseryman at Sturmer; both Hogg in the *Fruit Manual*, and Bunyard in *A Handbook of Fruits* state that Sturmer is near Haverhill, in Suffolk; Sturmer itself is in Essex.

As is necessary with late Apples generally the fruits should be allowed to remain on the trees for so long as possible. The tree is hardy and does well on either light or heavy soils. The illustration in Fig. 17 shows the shape of the fruits; those depicted are a little below natural size.

The flesh is crisp, juicy, greenish and pleasantly flavoured. The skin is green to greenish-yellow, and almost entirely covered with brown russet, with a tinge of dull red on the side next to the sun. It is a very distinct Apple and one that is easily recognised, the red flush on the russet being a pronounced character.

APPLE BEN'S RED.

Experience is a very dependable teacher; probably none better; but there are times, however, when experience, even in the same county, leads to quite different conclusions. As an illustration, there is a description which Mr. E. A. Bunyard applies to the Apple Ben's Red, in *A Handbook of Fruits* (Apples and Pears). He describes the flesh as "firm, pale yellow, sweet, aromatic." "A very useful fruit, valuable for its great cropping qualities." Mr. Bunyard is a Kentish grower, but obviously he has had quite a different experience with the variety to that of Mr. Weston. I have had a similar experience with Ben's Red, which was the reason why I commended it in my note. Had Mr. Weston stated that the class at Vincent Square was for Ben's Red only, my comment (vol. LXXVIII, p. 435) with regard to the judges would have been superfluous. Yet, the point that was in my mind holds good, *i.e.*, that those responsible for the show would not have arranged a special class for Ben's Red if they had considered the variety unworthy. *Geo. H. Copley, N.D.H.*

VINE MILDEW.

On reading the article on this subject by Mr. J. Wilson, in *The Gardeners' Chronicle* for November 28, 1925, I am forced to the conclusion that the action of sulphur in eradicating mildew is not generally understood. Raw sulphur itself will not do it. There must be sufficient heat (not less than 85°) to produce a sulphur vapour, and if this is produced in sufficient quantity in a closed house mildew cannot live.

Ordinary flowers of sulphur will retain much of its potency for a considerable time. When used for painting vines in late autumn or winter, it has no immediate effect, but if not washed off by syringing it will retain sufficient strength during the following season to prevent mildew developing, unless there is a new infection. There are various methods of using sulphur, but they all show that a portion of the chemical must be vaporised before any beneficial results can be attained. Campbell's vaporiser is effective if used properly, but it leaves a coating of dust on the berries. This may be removed with a syringe and clean soft water on the morning following vapourising, while the berries are still warm, and before there is dew on them. The water should be clean, without lime, and used abundantly (though nor forcibly) or there will be a deposit on the lower part of the berry. Where there is a goodly amount of bloom on the berries the water will no do harm. As a partial confirmation of this, I may state that I have brought home Grapes from exhibitions covered with dust, plunged them several times in a tub of clean water, hung them up, blown most of the water out of them with a pair of bellows, and exhibited them again.

Another plan is thus described in my little brochure *Vines at Longleat*, published in 1882: "The pipes are made hot while the ventilators are still open, a wet rag is wiped along a couple of yards at a time and sulphur is dusted on from a piece of muslin. In the evening after the sunheat has mostly gone and the pipes have been made as hot as possible, the house is closed, when a bluish mist will be seen to rise from the sulphur which will make one's eyes smart, and in the space of two hours will kill all the spores of mildew. It is scarcely safe to use such a severe measure before the Grapes have grown to the size of a small Pea."

But I have not found it necessary to resort to the last-named remedy for many years, painting with sulphur and soft soap in the winter having been found sufficient, excepting in one case. This was where a vine was planted outside a building and trained up some twelve feet, where it entered a house on the second floor. The inside portion was painted, but the outside was not, and there were some short growths on that part which probably carried mildew spores.

I must emphasize the fact that I never syringe vines excepting for the purpose of cleansing them or applying an insecticide, and the rods are never peeled or scrubbed, so the sulphur remains on them from year to year.

Another remedy is made by boiling quicklime and sulphur together and applying the mixture, after dilution, with a syringe. I forget the proportions, but probably it is the same thing as that sold under the name of lime sulphur. The home-made article has the defect of discolouring white paint, but it is death to mildew as well as red spider, and may be used advantageously and freely where there is no paint.

We sometimes have cases of emergency to deal with. I had a case of mildew this last season when the fruits were about the size of small Peas. As the Grapes were intended for home consumption, a homely remedy was applied. Sulphur will not readily mix with clear water, but with the smallest quantity of soap it will do so. Sulphur was thus mixed to the consistency of cream, and applied abundantly over leaves and fruit with the finger against the nozzle of a syringe. The house was closed and the temperature rose to between 80° and 90°; the mildew was immediately killed. Very little trace of the sulphur could be seen on the fruit when it was ripe, and there were no marks on the berries, excepting those made by the mildew before it was checked.

I am reminded by a friend (a gentleman's gardener) that I frightened him by doing the same thing to his Grapes some years ago. There were no marks of the sulphur left, and he has never had mildew on his vines since. He now always gives his vines, when dormant, a good coating of sulphur and soft soap and never syringes them.

While the vines are quite dormant, soft soap, at the strength of half-a-pound to the gallon of water, may be used. It is important to paint thoroughly the parts around the buds. Growers are often told to be careful about damaging the buds, but well-developed buds have several coatings of scales to protect them, and if a soft brush is used, without applying undue pressure, they are not likely to be injured. The soap at this strength will do a great deal towards killing the spores of mildew, and also the hibernating red spider, supposing the latter has not been eradicated while it was still active. Should a few of either of these enemies be left alive they are most likely to succumb to the action of sulphur when the heat becomes sufficient to vaporize it.

Sulphur, when used properly, deserves more credit than it usually gets. During the summer of 1924 some Roses were badly affected with black spot disease on the leaves, and many of the leaves dropped. The plants were syringed with a mixture of soft soap, four ounces to the gallon, and as much sulphur as could be forced through the nozzle of a powerful syringe. Two or three hot, dry days fortunately followed, and the disease spread no further. During the past season there has been very little of the disease on the plants thus treated, though others in the immediate neighbourhood were badly infested. *Wm. Taylor, Bath.*

—Mr. Wilson's remarks on vine mildew were very interesting and useful, as this disease has always been very troublesome and worrying to growers. I have seen numerous remedies tried, but none was of avail in completely eradicating the disease. I have, however, been successful in doing this with a preparation applied in winter.

In February, 1924, when I came to these gardens, I was informed that mildew was very prevalent in the vineries. One is a Muscat house, and in this vinery mildew was very bad indeed. It was too late to proceed with the winter treatment of the rods that year, and my only effort was to check it during the growing season. Mildew appeared a few weeks after the berries had passed the stoning stage, and in a very short time, every leaf, bunch and berry was covered with white. It was necessary to use my special specific at that time of the year in liquid form and spray it on the vines. The mildew was killed, but it appeared later, and the spray fluid slightly damaged the foliage, proving that it should be prepared as a paste and used during the resting stage on the rods and pipes. The chief ingredient in my composition is salt. A mixture of sulphur, Gishurst's compound and carbolic soft soap is made, and half-an-ounce to one ounce of salt used in every pint of the mixture. Spraying the woodwork of the house is, of course, essential. In December, 1924, I treated the vineries as stated, and not a speck of mildew has shown itself on the vines since, although no vineries were worse affected with mildew than those here. Spraying the rods should be discontinued when the vineries are started, otherwise the specific will be washed off when syringing the vines with clear water. *F. W. Dodd, Parkfield Gardens, Mill Hill, N.W.7.*

VEGETABLE GARDEN.

THE CULTIVATION OF ONIONS.

My experience as a county lecturer leads me to believe that there are two classes of Onion growers; one which treats the crop with special care, and one which leaves the crop largely to look after itself. Shortage of labour is not always the factor that places growers in the second class. The favourable effects of special care are so well marked, however, that the former class is increasing every year, and I propose to describe the method by which it works.

The seeds are sown in early January, in a temperature of 65°, and when the seedlings have germinated and stand erect they are transplanted into boxes or thumb pots. The latter are the best media for the nursery-bed stage, because the seedlings may be planted out without experiencing a check in their removal. The actual time for planting out varies in accordance with the weather, but mid-April is the date for which to aim.

By mid-April the Onion seedlings should be hardened off thoroughly. If the crop is to be a success, the plants should be set in soil which has been thoroughly worked to the depth of two spits during the winter. The present is an appropriate time for the work, and farmyard manure at the rate of one ton per one hundred square yards should be incorporated as it proceeds. A dressing of soot and wood ash, each at the rate of four ounces to the square yard, will prove helpful if forked in to a depth of four inches a fortnight prior to planting out.

The knowledge that Onions appreciate a firm soil is deep-seated in the gardener's mind, but zeal may proceed before wisdom in this matter. Naturally tenacious and firm soils are often artificially made too firm for the success of the crop. Light pressure only is needed in such cases. Light soils require considerable pressure in order to give them the proper texture. Onions should have one foot of space each way for proper development, and when planting, it is advisable to bury the bulb to about half its depth.

After planting, the cultivator may rest on his oars until the critical time for feeding arrives. Feeding too early results in thick necks, and feeding too late causes the bulbs to split. I have evolved a system of feeding the three thousand plants which I cultivate annually, and it answers well. It is based on a modest knowledge of plant nutrition.

The period during which the crop receives special feeding covers six weeks and is divided into three stages of a fortnight each. During the first fortnight the formation of roots is encouraged by four applications of superphosphate (30%), at the rate of one ounce per plant. [? Eds.] During the second fortnight each plant receives four applications of nitrate of soda, at the rate of half-an-ounce, for the purpose of stimulating leaf-development. During the third fortnight the plants are ready for storing material in the bulb, which process is assisted by four dressings of sulphate of potash, each plant receiving half-an-ounce. In a forward season I commence feeding in mid-June; in a late season at the end of that month.

When the crop shows signs of ripening it is a good plan to assist nature in regard to maturation by bending the stems over, about four inches above the bulb. During September the crop should be lifted, the bulbs ripened thoroughly and stored in a dry, frost-proof place.

No discussion on Onions is complete without some reference to the Onion fly, which makes its withering presence felt every year. I maintain that the method of culture above described is in itself a powerful weapon in the armoury of preventives, because the plants are strong all through their season of growth and therefore able to resist attack. This method of culture, however, is not in itself sufficient to give complete immunity, which is only secured by fortnightly applications of paraffin emulsion, from the date of planting out to mid-August.

After testing many varieties of Onion, I believe Premier, Ailsa Craig and James' Long Keeping to be the best. *Geo. H. Copley, N.D.H.*

HOME CORRESPONDENCE.

The Editors do not hold themselves responsible for the opinions expressed by correspondents.

The Destruction of White Fly.—I was greatly interested in Mr. Copley's remarks (vol. LXXVIII, p. 488) on this subject, but my experience differs a little from his. I have known white fly as a greenhouse pest since 1900, but no special effort was made to destroy it, and it did not appear to increase. It became a menace in 1918, and from then until 1922 it threatened to destroy all our inside crops, and was rapidly spreading to those outside. Why it should have so suddenly reached epidemic form I can only ascribe to two theories. (1) Garden staffs became greatly depleted from 1914 onwards, making cleanliness in plant houses impossible; (2) during this period many large plants growing in brick pits or large pots were destroyed; may be these plants harboured insects that did no harm to vegetation, but which preyed upon the eggs of the white fly or even upon the white fly itself. Since 1922, I am happy to state that it is my experience this pest is diminishing in numbers. With regard to host plants, the white fly has a decided preference for certain kinds, and although it will exist on others it will not lay its eggs upon them. I could never understand how such a frail insect could lay such a large egg, but I have since discovered that when the eggs are laid they are invisible to the naked eye, but grow until they develop into the fly. Heat seems to be a large factor in determining the length of time required to hatch the eggs. When a house is fumigated with tetrachlorethane, or one of the preparations containing this chemical, most of the flies are killed, but some are only narcotized and revive in twenty-four hours; the eggs are not affected, and may start hatching out next day, and this process goes on; therefore, even a weekly fumigation will not entirely destroy this pest, although it will hold it in check. Mr. Copley was fortunate if he found the tetrachlorethane did no damage in a mixed house. Some plants will not withstand this chemical, and unfortunately, there is absolutely no guide to tell which plants will suffer. I gave a house of mixed succulents a very light fumigation recently and found that while Cotyledons were unharmed, Kalanchoes suffered, but what is even more remarkable some species of the genus Crassula were not harmed, while other species suffered badly. Care should be taken to test everything: it is a good plan when fumigating a house to put a plant of as many different subjects as possible into the house, and then make notes for future reference. Between the fumigations I spray the undersides of the leaves with XL ALL insecticide, at a strength of one part to twenty parts of water. *P. Meyer, Cardiff.*

Late-flowering Varieties of Chrysanthemum maximum.—It may interest your readers to know that I have raised two distinct varieties of Chrysanthemum maximum from a cross-fertilised flower, and both came into bloom in November from seeds sown late in spring. They are distinct from each other, one having a perfectly smooth stem and leaf, while the other has white, hairy down on the stem and underside of the leaf. In each variety the flowers are white, I think they may prove valuable for cut flowers, grown in a cold house during winter. Are these the first of their kind to come into flower the first year from seed? The experience of others would be interesting. *W. Sellens, Woking.*

Schizostylis coccinea.—On page 447, *A. T. H.* repeats the often printed story that a pink-flowered variety of this plant, to which Mrs. Hegarty's name has been attached, originated in an Irish garden: no doubt the particular plant was first found there, but it may be as well to place on record the fact that in the old Orange Free State and Natal, a pink-flowered variety grows on spruit banks side by side with the red-flowered type. Roots of it were sent to me in 1905 by a friend who was then at Witbank, but as it seemed a poor thing, and far less desirable than the type, it eventually found its way to the rubbish heap. *A. Grove.*

Carnation Diseases.—Mr. Allwood is doubtless right when he states (vol. LXXVIII, p. 455) that Carnation stocks should be changed more frequently. The obstacle to doing so is the cost of renewing stock at present prices. This is the reason why gardeners are compelled to exchange cuttings with each other. The remedy lies with the Carnation specialists, who would doubtless benefit themselves as well as growers if substantial reductions in prices were made. They might follow the lines adopted by the Chrysanthemum specialists; with them, a novelty remains a novelty for only one season. The next year it can be purchased at one-fifth its original price, and soon reaches lowest prices side by side with the oldest catalogued varieties. Can the same be said of Carnations? I saw recently, catalogued and priced at five shillings each, a variety which we grew more than a dozen years ago! *Marmion.*

SOCIETIES.

BRITISH MYCOLOGICAL.

AT a meeting held recently at University College, London, Mr. J. Ramsbottom, who occupied the Chair, gave an account of the life, personality, and activities of the late Mr. William Norwood Cheesman, J.P., F.L.S., who had died during his year of office as President of the Society.

Miss Lorrain Smith exhibited woollen and silk material that had been dyed with Lichens, and also specimens of the plants used. Under the name of "orchil lichens" are included all those that give a red colouration and are used in the preparation of litmus, though Lecanora tartarea, a crustaceous Lichen, is the one chiefly used.

Mr. S. Dickinson demonstrated a simple method of isolating and handling single spores and bacteria. The spores or bacteria are moved from place to place under continual observation in a local thickening of water film. This film is formed between a film agar and a fine glass rod, which can be moved in three dimensions by a special apparatus. The apparatus was demonstrated to the audience by means of an epidiascope.

Mr. Alex. Smith described Penicillium diseases of Gladiolus and Narcissus. Both diseases are rots which occur in storage. Whether the disease originates in storage or in the soil prior to harvesting is in both cases a matter for investigation. In Gladiolus the rot appears to spread from the remains of the previous year's corm, but it had been shown experimentally that the rot can be initiated by a cut infected with the proper species of Penicillium. So far this artificial infection has been found only in corms which were planted in soil or fibre, and it has not been possible to initiate the infection under storage conditions. The causal Penicillium is characterised by the production of pale pink sclerotia and abundant coremia in some media.

In the Narcissus disease the Pencillium appears to be fairly close to P. chrysogenum Naturally-infected bulbs are generally dried up and bear abundant spores between the dead scales. The disease appears to gain entrance *via* the dead tops of otherwise healthy scales. It fails to pass through epidermis and the whole bulb becomes affected from the base. Artificial infection has been secured by bruises in moist but not in dry, conditions.

Mr. W. Buddin and Miss E. M. Wakefield gave an account of the life-history of a fungus parasitic on Antirrhinum majus. Cercosporella Antirrhini, Wakef., a parasite of cultivated Antirrhinums which was first described in 1918, has been found to have another stage in its life-history, a pycnidial form belonging to the genus Hetercpatella. Pycnidia are produced in pure cultures on certain media, and have been found also on dead, overwintered stems of Antirrhinum. The connection with the parasitic Cercosporella has been proved by inoculations, No ascigerous stage has as yet been found, and possibly this does not occur, the winter pycnidia being sufficient to ensure the survival of the fungus from season to season. The disease is one of cool weather, the optimum temperature for growth of the fungus being about 18° C. Similar temperature relations are known for Heteropatella cercosperma (Rostr.) Lind, and recorded observations appear to indicate that the whole genus may be one specially adapted for cooler climates. The pycnidial stage of the Antirrhinum disease shows little morphological difference from other species of Heteropatella, but no doubt the characters of the ascophore (Heterosphaeria sp.) are necessary for the distinction of species in this group. One species is known to occur on the closely allied host plant, Linaria vulgaris, but the occurrence of a parasitic hyphomycetous stage appears to be a new development in the life history of the fungi.

Mr. J. Ramsbottom then gave the fourth part of "Fragmenta Mycologica" which included photographs of Onygena equina on sheep horns and on the horn stem of an old pipe; one of the somewhat previous tombstone of the American mycologist C. G. Lloyd; a silver milk jug with a fungus (? Lactarius) depicted on it, part of a tea service presented by the Woolhope Club to the late Worthington G. Smith; and an account of the strange behaviour of Enderlein in attempting to obtain priority in systematic work on Myxobacteriaceae to the disadvantage of Jahn, an authority on the group.

Mr. W. J. Dowson described a core-rot of Apples caused by Sclerotinia fructigena, an account of which appeared in *The Gardeners' Chronicle* of Dec. 19, 1925, p. 479. There were several interesting exhibits.

Obituary.

George William Cummins.—We regret to learn that Mr. G. W. Cummins passed away on New Year's day at the age of seventy years. For many years past he had resided at Croydon, and, although little known to horticulturists of the present generation he was famous among the older gardeners for the success with which he managed the late Mr. A. H. Smee's interesting garden on the banks of the Wandle—The Grange, Hackbridge. This position he occupied for sixteen years, and during that period he was a member of the Royal Horticultural Society's Fruit and Vegetable Committee. His successes as an exhibitor included no fewer than twenty-one R.H.S. medals, three of these being silver-gilt Knightian medals. He was an especially clever fruit grower, and received special awards for collections exhibited at the Apple and Pear Conference held in the old R.H.S. gardens at Chiswick, and at the Guildhall show, in 1890. The Surrey County Council recognised his services as an exhibitor and his work on behalf of domestic gardening. While at The Grange, and with the support of Mr. Smee, Mr. G. W. Cummins founded and was secretary of the Beddington, Carshalton, and Wallington Horticultural Society, which used to hold an extensive and instructive exhibition on each August Bank Holiday, when the late Mr. John Wright (*Journal of Horticulture*) and the late Mr. George Gordon (*Gardeners' Magazine*), acted as judges over a long period of years. After the death of his wife, Mr. Cummins went to Mablethorpe, Lincolnshire, and established a nursery and florists business. Later, he came south again, and was appointed gardener at the Croydon Borough's Isolation Hospital. In former years he was a frequent contributor to the horticultural press, and for half-a-century he was a careful and critical reader of *The Gardeners' Chronicle*, to which he sent notes of horticultural events that came under his notice. The remains were interred at Beddington Churchyard on January 5. Four sons and four daughters mourn the loss of a kindly father.

S. B. Dicks.—A valued friend of and contributor to *The Gardeners' Chronicle*, Mr. S. B. Dicks, passed away at his residence, West Norwood, on Monday, January 4, and we deeply regret the loss to his family, to horticulture and to ourselves. Mr. S. B. Dicks was a few months over eighty years of age; spent a very active life in the wholesale seed business, and for about sixty years was continuously in the service of Messrs. Cooper, Taber and Co., although he entered service with Messrs. Beck, Henderson and Child, a firm that, under various titles, gradually evolved into the present extensive business at Southwark Street, as Messrs. Cooper, Taber and Co. Our friend had a charming personality, was widely read and had a great fund of information concerning vegetables, their origin and uses, far beyond that possessed by members of his trade. He travelled widely in connection with the business of his firm, and at one period of his life made an annual visit to the seedsmen and seed-growing districts of the United States. He also visited regularly the seed-growing districts of France, Germany, Austria, Italy and Hungary, and even went further afield, to Arabia, Egypt and South Africa. A keen observer, and having a splendid memory, it was small wonder that he was consulted frequently upon those unusual but interesting and often very important matters that so frequently arise in any business. Although he paid special attention to vegetables and their seeds, he had a great love for florists' flowers, and for many years interested himself in Sweet Peas; indeed, he was the first to work out the history of this popular flower, and his comprehensive article which appeared in the *Florists' Exchange* in 1897 has been the foundation of all historical notes which have appeared in succeeding years. He took part in the celebration of the Bicentenary of the Introduction of the Sweet Pea into England in 1900, and contributed a historical paper to the conference on that occasion, as he also did to the National Sweet Pea Society's Conference in 1921. The keenness with which he followed up any point of interest was demonstrated in his endeavour to clear up the mystery by which the Sweet Pea came to be regarded as a native of Ceylon. He was one of the founders of the National Sweet Pea Society, its Chairman in 1903, and a member of its executive and floral committees for many years. This Society recognised his services by presenting him with the Henry Eckford Gold Medal in 1923. As a member of the Royal Horticultural Society's Fruit and Vegetable Committee, he rendered admirable service both at Vincent Square and at the Society's trials at Wisley; in recognition of his life-long service in his special branch of horticulture the Royal Horticultural Society recently awarded him the Victoria Medal of Honour in Horticulture, but, alas! he passed away without receiving the actual medal, which is usually presented at the Society's annual meeting in February. We shall miss his kindly greetings, his pleasant facetiousness, and his ready help, and our readers will regret that his series of informative articles on vegetables has come to an end. To the sons and daughter of our friend we offer deepest sympathy.

Rev. Prof. George Henslow.—The news of the death of this venerable botanist and distinguished horticulturist will be learned with the deepest regret by our readers. He died at Bournemouth on December 23rd, at his home at Danehurst, Branksome Wood Road, in his ninety-first year. He was born on March 23, 1835, and was the son of one of the most distinguished botanists this country has produced—the Rev. J. Stevens Henslow, rector of Hitcham, Suffolk, and Professor of Botany at Cambridge University. The late Professor George Henslow was lecturer in botany at St. Bartholomew's Medical School from 1886-1890, and he was also lecturer in botany at the Birkbeck Institute and Queen's College London. Gardeners will remember him chiefly for his association with the Royal Horticultural Society, to which he was honorary Professor of Botany for very many years. At one time he lectured frequently at the meetings of the R. H. S., taking for his subjects some of the plants in the hall, and giving a popular description of their structure, etc., in a most interesting manner. He was the author of many botanical works, including *The Origin of Floral Structures; The Origin of Plant Structures; Botany for Children; How to Study Wild Flowers; The Uses of British Plants; Plants of the Bible*, etc., etc. His chief work of interest to gardeners was *The Origin and History of Our Garden Vegetables and their Dietetic Values.* The deceased was one of the original sixty recipients of the Victoria Medal of Honour in Horticulture.

Leon Kerkvoorde.—We greatly regret to see in our contemporary, *La Tribune Horticole*, of Brussels, an account of the death of M. Leon Kerkvoorde, a well-known Belgian nurseryman He was ill for less than a month, and will be greatly missed, for he was everywhere beloved for his kindly helpfulness, his indefatigable industry, and his devotion to the interests of Belgian horticulture. All English visitors to the Ghent "Floralies" will remember his handsome, kindly features, and his absence from the fêtes of 1928 will cast a gloom of which all will be aware. He leaves a widow and several children, for whose sorrow we feel much sympathy.

John Leyden.—A noted Scotch horticulturist in the person of Mr. John Leyden has passed away at the advanced age of 83. In his earlier days he was the champion Peach grower in Scotland, and was a prominent prize winner at the more important shows in England and Scotland. He began his gardening career at Stravaar, with the then chamberlain of the Duke of Argyle, and was afterwards employed at Dalziel House, Motherwell, and at Mavisbank, Polton. Thereafter, for half-a-century, he had charge of the gardens at Whitehill House, Midlothian. Mr. Leyden retired a number of years ago.

ANSWERS TO CORRESPONDENTS.

Grubs in Seedling Boxes.—*E. J. P. M.* The grub is the larvae of a snouted beetle or weevil. It probably belongs to the genus Otiorhynchus, of which there are several species of economic importance. One or two species are common in greenhouses, and being night feeders, usually escape notice. Presumably this is what has happened. First a general effort should be made to reduce the number of adults. To do this they should be searched for at night by the aid of a lantern or torch, remembering always that they drop at the slightest movement. A flat tin, such as a housemaid's sweeping pan, covered with grease, forms a useful weapon to catch them after they are shaken from the plant, or a flat tin with a little paraffin at the bottom serves the same purpose. Secondly, some effort should be made to make the potting soil distasteful. To do this, one of the naphthaline compounds, such as vaporite, may be mixed with the soil, according to directions The soil should not be used for a week or so after mixing in the vaporite. The most important point, however, is to get rid of the adults.

Vine Border. *B. McP.* Much depends on the texture of the soil as to what should be added to it, indeed, the texture is, in some cases, more important than the chemical composition. A soil that is too light will not produce Grapes of good quality. It has sometimes been found advantageous to mix powdered clay with very light soil. On the contrary, a soil which binds is not suitable, for it will not be sufficiently aërated. Again, potash is a most important item, which in some districts is very deficient. A small excess of potash in the border will do no harm, but an excess of nitrogenous matter will do so. Therefore, if there is a large amount of vegetable matter in the soil, it is not well to add anything that will enrich the ground with nitrogen for the first year or two. In ordinary cases, half-a-peck of lime rubble, such as mortar from an old building, but less than this if the soil is light, a six-inch potful of fine bone-meal (not chemically treated) and four ounces of sulphate of potash should be added to each cubic yard of soil. As the last-named is quickly used up in some soils it should be replenished every year on the surface, at the rate of two pounds to the perch. Charcoal is not a plant food, but it helps to keep the soil open and sweet. It is well to place the bonemeal, potash and nitrogen in the upper half of the border. Three feet is more than enough for depth of soil; you will therefore have ample room for drainage materials. It will be advisable to plant the vine of Madresfield Court near the door, as it requires, at certain times, more ventilation than White Muscats.

REMARKS.—Increased supplies are arriving from home-growers, the Channel Islands and the South of France, and prices throughout are on the down grade. Amongst Chrysanthemums, coloured varieties show signs of finishing, but the quantities of white blooms and bunched spray white appear sufficient for the present demand. Daffodil Golden Spur and all Tulips are much improved in quality; the latter include La Reine, Thos. Moore, Yellow Prince, Brilliant, W. Copland, Mon. Tresor and Gris de Lin. Roses are scarce; Madame Butterfly, Columbia, Madame A. Chatenay and a few blooms of Richmond are the best sorts available. There will be nothing reliable until the new crop is ready in about a fortnight's time. Large consignments of white Lilac and Tulips have been arriving from Holland during the past week, also a few bunches of Prunus triloba. Supplies are increasing almost daily from the Channel Islands. These consist of Freesias, Anemones, Richardias (Arums), Daffodils, Narcissi Soliel d'Or, Grand Primo, and Paper White, and Smilax. Supplies from France are much improved in quality, and prices are lower now than for some weeks past; this should increase the demand for these blooms. Small consignments of White Stocks are the newest arrival from this quarter.

REMARKS.—Except for one or two special lines, business has been on the slow side during the week, but some improvement is expected in the near future. Peaches, Apricots and Plums are the principal fruits of the earliest arrivals from South Africa, but there is not a brisk demand for them at the moment. Stocks of Apples from the United States and Canada are ample for the trade that is ruling just now, and quotations are a shade easier. Oranges are plentiful and meeting something slower than a moderate enquiry. The competition of other fruits has probably been the reason for slightly lower prices at which Bananas are now selling. Fair quantities of English Apples are being sent to market, and in some instances the fruits are well packed and in excellent condition. Bramley's Seedling, Lane's Prince Albert and Newton Wonder of that description are selling fairly well. While Cox's Orange Pippin, generally, is past its best, some fine samples of this variety are still available and selling at satisfactory prices to the growers. Trade in choice vegetables is only fair, and such produce as forced Potatos, Beans, Peas and Asparagus might sell with more freedom, even if their prices are somewhat exclusive. Madeira Beans have arrived this week in better condition, and have realised higher prices. Mushrooms have shown some fluctuation in value, but at the time of writing their prices seem more stable, fewer having been shipped from France. Tomatos from the Canary Islands have, on the whole, been somewhat unsatisfactory, a great proportion having come to hand very much out of condition and of an inferior quality. A few top-grade marks are, however, selling well. A sprinkling of Cucumbers is still arriving, but their prices are rather high. Cauliflowers, mainly from Northern France, after a period of good prices, are now coming in very poor condition, due, no doubt, to the recent severe weather, and they are difficult to sell even at prices which barely cover cost of freightage. Salads are selling very well and will continue to be in demand. Green vegetables are fairly plentiful and are making good returns. Trade in new Potatos from the Azores and Canary Islands is anything but brisk, and there is room for much improvement. Old Potatos are a steady trade without being unduly brisk, and with little or no variation in prices.

TRADE NOTE.

OUR correspondent, who furnishes us with the weekly report of the Glasgow fruit, flower and vegetable trade, sends the following note on the market-growing industry in the Glasgow and West of Scotland districts:—

"While 1925 has been a year of widely fluctuating prices in the marker-grower's business, I think when the profit and loss account is made up for the twelve months it will be found in most cases that the average has not been unsatisfactory. In my endeavour to obtain an expression of views on the subject, I found that differences of opinion prevailed, and there was absence of unanimity regarding any particular product. One nurseryman confessed that it had been one of the most difficult years in his experience; another believed in taking a long view of things, and admitted that when the good weeks were put against the lean periods he saw no reason to complain, while an Ayrshire optimist was quite well pleased with prices and added, 'We have had quite a good year.' One grower, of a judicial turn of mind, argued on the basis of careful observation, pointing out that the law of compensation usually worked out equitably, and that what was lost in bulbs was more than made up by Tomatos and late Chrysanthemums. One may reasonably conclude that the Scotch nursery trade is in a healthy condition, and that a further expansion of the glass area will be witnessed in the near future."

THE WEATHER, DECEMBER, 1925.

THE mean temperature in the screen for the month was 35.3°, or 2° below normal. The highest maximum readings of 50° were noted on the 7th, 8th and 29th, while the lowest minimum of 20° occurred on the 19th. This gives an absolute range of 30°. The lowest maximum of 29° and the highest minimum of 40° were recorded on the 25th and 17th respectively. In the open the grass minimum thermometer registered frost on twenty-one days, and the lowest readings of 13° were taken on the 19th and 25th. The temperature of the soil at one foot deep, at 34°, was practically stationary throughout the month. Precipitation totalled 2.29 inches, or slightly under the average. This rainfall was distributed over eighteen days, and the greatest fall of .80 of an inch occurred on the 17th. Snow fell on seven days, and snow lying was recorded on fourteen days. Bright sunshine is not expected to reach a high total in December. The 40½ hours recorded is just about normal, and gives a daily average of 1.3 hour with a percentage of 19. The brightest day was the 16th, which contributed 5.1 hours sunshine. Barometric pressure was highest on the 4th, viz., 1.635 mbs. (30,564 inches), and lowest on the 29th, viz., 973.2 mbs. (28,741 inches). The last ten days of the month were a period of low pressure. Winds, which were mainly south and westerly, veering occasionally to north-west, were never of great force. *W. MacLelland, The Meteorological Station of St. Andrew's Provincial Committee at the Training College Gardens, Mayfield, Dundee.*

The Germination of Seeds.

IT is interesting to find that botanists are, as shown by their published work, taking an increasing interest in the physiology of germination. Every gardener knows what vagaries seeds exhibit in their germination and attention has often been drawn in these pages to some of these vagaries. But it will not be until research has busied itself with the problems much more than it has done at present, that we may expect that full enlightenment without which scientific discovery can be applied only tentatively to practical garden problems. Of recent investigations into the process of germination and the conditions which control it, the most interesting—at all events from the scientific standpoint—is the influence exerted by light on germination. Experiment shows that seeds may be separated into two or more classes according to their response to light. There are certain kinds of seeds, species of Tobacco (Nicotiana), Salicaria, Veronica and others, on the germination of which light exerts a remarkably accelerating action. In the case of seeds belonging to this category even a very brief exposure to light may result in a large increase in the percentage of germination. There are, however, other seeds which behave contrariwise, exposure to light producing in them an inhibition, that is, a checking of germination. Furthermore, among seeds belonging to the light-germinating class a number of facts of significance have been discovered. In the first place, it has been shown that acceleration of germination may be induced by an almost incredibly short exposure to light. In the second place, it appears that for a given increase in germination to be obtained what matters is the quantity of light and not the intensity. Light of low intensity shining on the seeds for a longer time produces the same effect as light of higher intensity applied for a correspondingly shorter time. Hence, if the light be of a very high intensity, the time of exposure necessary to raise the percentage of germination, as compared with that which occurs in unlighted seeds, may be a matter only of a second or so. These facts are interpreted to mean that light exercises a photochemical action on some part or other of light-sensitive seeds and that as a result of this action some substance—of as yet unknown nature—is produced which acts as a stimulator of the germination process. In support of this conclusion it has been shown that seeds which have been stimulated by light may show the enhanced percentage of germination when, subsequently, they are sown in darkness, and it is also claimed that the light-stimulatory substance may be washed away from the seeds so that they, when set to germinate, no longer show the higher percentage of germination. In the third place, experiment also indicates that whereas with light-sensitive seeds, if the quantity of light as measured by the product of intensity and time passes a certain point, then it acts not as a stimulator, but as a check. For example, seeds of Mercurialis annua are capricious in their germination, germinating in some conditions at the rate of about 10% at harvesting, and gradually germinating more freely as the years go on, 14% in the first to the third year, 30% in the fourth, and falling to 16% in seven years. Although the seeds germinate better in darkness than in light it has been shown by Mr. P. Gillot* that a relatively brief exposure to light increases the percentage of germination (from 48% to 60%), whereas a longer period of exposure depresses it to 28%. Another fact of interest is that the speeding-up effect which light exerts on some seeds may be produced also by certain chemicals, dilute hydrochloric acid for example. It would seem from these recently discovered facts that seeds contain light-sensitive substances which break down very readily under the influence of light, with the formation of substances, some of which activate and some of which may retard germination. Pending further discoveries, however, gardeners must continue to try all kinds of methods to induce refractory seed to germinate. Of these methods, there can be no doubt but that stratification is the safest and best. By placing the seeds in layers between thin layers of moist, fine soil in pans and sinking the pans in ashes, the germination of even the most refractory seeds is quickened. Mr. Gillot, whose work has been referred to already, found that by stratification he could raise the germination of seeds of Mercurialis annua from some 14 to 90 or more per cent. It is also worthy of note that for purposes of stratification soil seems to give better results than sand, though why this should be the case baffles understanding no less than the many other peculiarities of germination — Solomon might well have added to his catalogue of mysteries—"the way of a ship in the sea," etc., the way of the seed in the ground. Finally, although it has not so far as we know yet been made the subject of exact experiment, the gradual failure of aging seed to germinate at all will probably be found to be due to the accumulation in the seed of specific chemical substances which act as slow poisons. Perhaps, indeed, the very substances which, when found in small quantity, accelerate germination, will be found, when produced in larger quantity, to slow down and finally to arrest the life process of the seed.

National Rose Society.—The forty-ninth annual general meeting of this Society will be held at Caxton Hall, Victoria Street, Westminster, on Tuesday, January 19, at 2.30 p.m. Members of the Society are cordially invited to remain for tea and light refreshments after the meeting, which is expected to be over at 3.45.

Plans of Field Drains.—Where new gardens are being made or areas of farm land are being added to a garden, a plan showing the position of land drains would prove useful, but such plans are rarely available. No doubt the general lack of such information and the increasing need of such knowledge led the Earl of Chichester to propose the following resolution at the December meeting of the Council of Agriculture:—"That the Ministry of Agriculture and Fisheries be asked to introduce legislation making it compulsory in all future cases where agricultural land is drained by means of underground pipes, that a plan of the drains be attached to the deeds of the property, and also to any agreement for the letting of such land."

The Kew Hand-List of Coniferae.—The latest of the new series of *Hand-Lists* issued from the Royal Botanic Gardens, Kew, is the one dealing with Coniferae, Cycadaceae and Gnetaceae* cultivated at Kew. This is the third edition of such a *Hand-List*. In the first edition 227 species, with 340 varieties, belonging to thirty-seven genera, were listed. The second edition, which was revised by the late Dr. Masters, enumerated 246 species, and 451 varieties, whereas in the present issue (third edition) the number of Coniferous plants enumerated includes 288 species and 398 varieties, or forty-two more species and fifty-three fewer varieties than were included in the 1903 edition. In the new edition, however, there is published for the first time a list of the Cycads cultivated at Kew, which form what is probably the finest collection of these plants in existence. The third edition also differs from its predecessors by the inclusion of a section which deals with the economic properties of Gymnosperms. The genera of living plants are arranged alphabetically in their families, instead of in the botanical sequence followed in earlier editions. In the second section, however, the botanical sequence is maintained. Reference is made in the preface to the difficulty of cultivating Conifers successfully at Kew owing to adverse atmospheric conditions, and also to the establishment of a national collection of Conifers at Bedgebury, near Tunbridge Wells, under the control of Kew, in co-operation with the Forestry Commission.

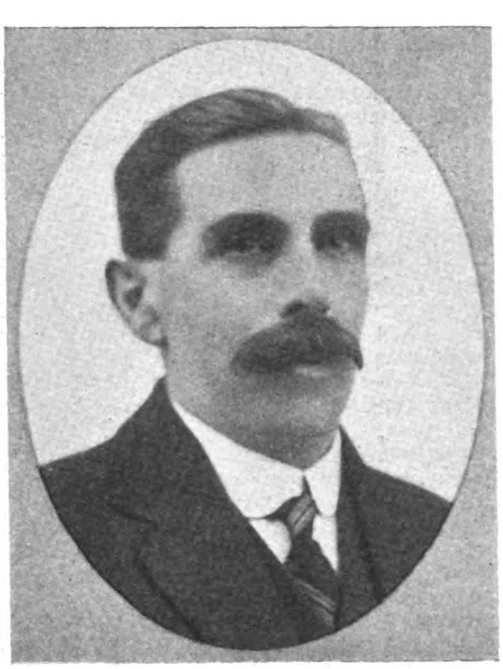
Two Interesting Calendars.—A useful calendar has been issued by the City of Birmingham Estates Department to its tenants. There are fifteen sheets, with a printing surface of seven inches by nine-and-a-half inches. An illustration of horticultural interest appears on each of the twelve calendar sheets, and those of Chrysanthemums, Fruit Garden at Hall Green, Roses, Tenant's Garden at Erdington (2), and Prize-winning Exhibits of Apples, are reproductions in colour. The gardening reminders are necessarily brief, but they are timely and useful, as also are the household hints, one of which for January, is "Don't bang your door if you do not think it closes properly—try and find the reason." The last three sheets contain particulars of a "Cropping Scheme" for the vegetable garden; and fruit-pruning charts, the latter containing no fewer than sixteen diagrams to assist the text. The second calendar is from the Yokohama Nursery Co.; it is a daintily pretty work, enclosed in a neat cardboard wallet; the calendar for each month is printed in colours on a thin, tough card slip, but all the slips are tied together loosely, with a loop above the one for January; when this loop is held up or slipped over a nail, the calendar for the year falls into proper order and becomes an attractive picture of a Pagoda with a suitable background.

Special Presentation to Mr. B. H. Maclaren.—It is with great pleasure we learn that the Brighton Corporation has presented its Parks Superintendent, Mr. B. H. Maclaren, with an honorarium of £200 "for services in connection with special work carried out by you in the past outside your ordinary duties."

Concession to Scotch Potato Growers.—The Board of Agriculture for Scotland has issued a general licence authorising occupiers of holdings not exceeding half-an-acre in extent, and of private gardens, to plant during the season of 1926 Potatos of certain first-early varieties which are not immune from Wart Disease, on condition that the resultant crops will be lifted not later than August 15, except in the counties of Aberdeen, Banff, Caithness, Inverness, Kincardine, Moray, Nairn, Orkney, Ross and Cromarty, Shetland and Sutherland, where the crops shall be lifted not later than August 31.

Garden Pictures at the Royal Academy.—John Sargent is regarded as a portrait painter, and the loan exhibition of his works which opened at the Royal Academy on Thursday, the 14th inst., consists in the main, of portraits. Nevertheless, there are a number of landscapes, and some—a few—of garden interest. As a matter of fact, one of his best known pictures, the favourite "Carnation, Lily, Lily, Rose" is a garden scene, depicting two children standing knee-deep in flowers, lighting Chinese lanterns, tall Madonna Lilies towering over their heads, and, in the foreground, a tangle of different-coloured Carnations. Number 9, The Villa Torlonia, shows a formal Italian garden with a fountain enclosed by a stone balustrade, the dense foliage of luxuriant trees forming a shady background. In 111, we find another Italian garden, that of the Villa Collodi, near Lucca; the central portion of the picture is occupied by a stature of Daphne. The Gates of a Château at Ransart (No. 124) is a study in battered masonry and broken, creaking gates, with a riot of foliage and flowers, against a sky of summer blue. In "Pines" (150), the chief feature is the brilliant light, against which the dark foliage of the trees looks almost blue. No. 287 is an oil painting of an old and broken rush chair, on which is a small glass vase with three Roses in it; the group is set in a deep green meadow. A Garden in Corfu (No. 286), shows a shallow, winding, stone stairway, stone parapetted, against a background of thick, shady trees, through and beyond which the deep blue of the sea is visible. No. 507 is a water colour, of which the subject is the Garden of La Granja, Madrid; the picture shows a shady, stone-edged pool, the water a soft green from the reflection of the trees which shade it; a few feet from the rim of the pool, across the stone path, are four stone figures. The whole effect of the picture is one of dark, quiet calm. Mr. F. D. Millet's house and garden in 1886 forms the subject of No. 557. A wide, gravel path is shown, with deep green grass on each side, in which grow Rose trees and tall Lilies. The house in the background is almost obscured by trees in their full summer foliage.

Mr. William R. Catt.—During 1925, Mr. W. R. Catt won *The Gardeners' Chronicle* Silver-gilt Medal offered at Shrewsbury Show for the best amateur's exhibit of hardy fruit, and, as in the previous year, was a successful competitor in other classes. He commenced his gardening career at Sittingbourne, with Mr. A. J. Thomas, then a frequent and successful exhibitor of hardy fruits at the leading English exhibitions. Here he received a training that laid the foundation of his success. After serving as journeyman in several southern gardens, including those at Caversham Park, Reading, and Theobald's Park, Hertfordshire, he was engaged as foreman at Lilleshall Hall, Newport, then the residence of the Duke of Sutherland, and a well-known centre of horticultural activity. Mr. Catt remained at Lilleshall for two-and-a-half years, and was then appointed gardener to A. H. Herbert Percy, Esq., at Hodnet Hall, Market Drayton, a position he filled most ably for twenty-one years, becoming a successful exhibitor at Shrewsbury and other west country shows. In September, 1925, Mr. Catt left Hodnet Hall to take up the position he now occupies as gardener to H. J. Jones, Esq., Buntingsdale, Market Drayton, Shropshire.



MR. W. R. CATT.

Law-breaking benefits a Botanic Garden.—The United States District Court has directed the Marshall to deliver to the United States Botanic Garden vessels used in the conveyance of illicit liquor and seized by prohibition officers, for use as receptacles for plants and shrubs. A good supply of barrels and beer kegs will be available from this source for the botanic garden. Our own botanic gardens at Kew and elsewhere have benefited by the contravention of the Customs law in this country, for much of the Tobacco, including cigars, and cigarettes, confiscated by the Customs, is placed at the disposal of the botanic gardens for purposes of fumigating the plant houses.

Prices of Insecticides used by Fruit Growers.—The Ministry of Agriculture has obtained information as to the prices ruling in North Kent, South Worcestershire and the Isle of Ely for the principal insecticides used by fruit growers. Nicotine of 96 per cent. purity is being sold at 14/- to 15/- per pound, and up to 16/6 per pound for small quantities, while grades of 40-45 per cent. purity are quoted in the Wisbech district at 6/- to 6/3 per pound, according to quantity. Spraying soap is purchasable at 32/6 to 37/- per cwt. in the different districts. Copper sulphate is quoted at 32/6 per cwt. in the Canterbury district, 31/- to 32/6 per 100 pounds bag at Wisbech, and 45/- per cwt. at Evesham. The price of lime sulphur (1.3 specific gravity) in South Worcestershire is 1/6 per gallon, in North Kent, 1/3 per gallon, and in the Isle of Ely, 1/6 to 1/9 per gallon. Lead arsenate is quoted at 9d. to 1/- per pound, according to make, at Wisbech, 10d. to 10½d. for single strength, and 1/8 for super quality in the Canterbury district, and 1/2 for 20 per cent., sold in cwts., in the Evesham district. Generally, prices are very similar to those ruling a year ago, but on the whole they are a trifle cheaper.

Success of an English Gardener in U.S.A.—Mr. W. N. Craig, nurseryman of Weymouth, Massachusetts, U.S.A., has been elected president of the Boston Gardeners' and Florists' Club. Mr. Craig's father was gardener at Levens Hall, Westmoreland, and before settling in America, Mr. W. N. Craig was engaged for four years at Lambton Castle Gardens, Durham, and subsequently he was employed in the nursery and seed business that his father had established at Kendal, Westmoreland. Mr. Craig is a valued correspondent to *The Gardeners' Chronicle*, and his notes on horticulture in America are always of interest. He is a life member of the Massachusetts Horticultural Society, and is connected with several other important associations, including the U.S.A. Sweet Pea, Rose and Carnation societies, the New England Gladiolus Society, and the Horticultural Club of Boston; for twenty years he officiated as secretary of the Boston Gardeners' and Florists' Club, an office which he has recently resigned, whereupon he was unanimously elected President of the Club.

Legacy to a Gardener.—The late Mr. Thomas Moss Cheesman of Elmore, Chipstead, Surrey, who died on October 29 last, bequeathed the sum of £250 to his gardener, Mr. Wood.

M. Correvon's Lectures in the United States.—M. H. Correvon of Floraire, Geneva, is proceeding to the United States where he has arranged to deliver between fifty and sixty lectures on alpine plants, rock gardening and other horticultural subjects at various places from Boston to San Francisco. He expects to be absent for about three months.

Poisonous Deposits on Apples.—As will be seen on reference to our market report, there has been a very considerable falling off in the sale of imported Apples as a result of the arsenic scare, caused by the deposition of arsenic (from arsenical washes) on imported Apples. In view of the cases of poisoning which have occurred, the County Council of Middlesex has issued a leaflet to all distributors of fruit in the county, stating that the public should be warned not to eat the skins of contaminated Apples, especially Newtown Pippin and "Newtown Oregons." The seller is recommended to brush such Apples with a wet brush and thoroughly wipe the whole surface, especially those fruits upon which any greyish-white powdery deposit in the two depressions around the stalk and calyx is visible to the naked eye. The safest plan for the consumer appears to be that of removing the skin entirely by paring.

Imperial College of Tropical Agriculture.—At the meeting of the Royal Society of Arts on the 9th ult., Professor H. Martin Leake, Sc.D., Director of the College, gave some interesting particulars of this institution in a paper which was read by Dr. A. W. Hill. It was started in 1922 as the West Indian Agricultural College, and owes its existence in great measure to Sir Francis Watts, the first Principal, who, as a Commissioner of Agriculture for the West

Indies, inspired the support of several gentleman. In 1923, at the instigation of the Rhodes trustees who contributed liberally to the funds of the college, the title was changed to that of the Imperial College of Tropical Agriculture. The training is adapted to those who desire to take up farming under tropical conditions, to those engaged in the administrative side of the Colonial Agricultural Services, and to those who desire to specialise in research work. Professor Leake stated that research is an essential feature of the syllabus, and a research station for Cotton growing has been established in proximity to the college. The course is open to any student who holds the matriculation qualification of any University in the Empire. In 1924-5, thirty-three students were in residence. In his concluding remarks, Professor Watts stated that he visualised the college as one of the recruiting grounds for the Colonial Administrative Services.

British Florists' Federation.—The ninth annual general meeting of members of the British Florists' Federation will be held at the Holborn Restaurant, London, on Friday, January 29, at 3.30 p.m. The general business will be followed by a discussion on "Imports of Flowers and the Effect of German Duties," to be opened by Mr. T. Windle. The seventh annual dinner will be held on the same day at the Holborn Restaurant, at 6.15 p.m. Tickets, 10/6 each.

Honour for Mr. W. B. Haines.—The Senate of London University has conferred the doctorate of Science in physics on Mr. W. B. Haines, of University College and Rothamsted Experimental Station.

The U.S.A. Embargo on Bulbs.—Notwithstanding the efforts that have been made by many horticulturists in America to persuade the U.S.A. authorities to remove the embargo on the importation of bulbs, Secretary Jardine has decided that the restrictions, as already ordered, should take effect as from January 1, 1926. These restrictions were authorised three years ago, and resulted in much opposition from various sources. As a result of the protest Secretary Jardine called a conference in Washington on November 16 and 17, 1925, when strong reasons for counteracting the order were forthcoming. Mr. Jardine states that he has given full consideration to the objections against the measure, but considers that there is ample evidence as to the danger of pests entering the country on the bulbs, and that it "undoubtedly justifies fully" the applications of the restriction. Limited quantities of bulbs will be admitted under special permit, for use as propagating stock, as novelties unavailable in the United States, or as material for investigational work. The following bulbs will, however, still be allowed to be imported (pending further determination of the possible risk involved in their importation) in unlimited number, and under merely a general permit according to Regulation 3 of Quarantine 37:—Chionodoxa, Galanthus, Scilla, Muscari, Fritillaria imperialis, F. Meleagris, Ixia and Eranthis.

National Chrysanthemum Society.—The annual meeting of members of the National Chrysanthemum Society to consider the annual report and accounts and to elect officers and the committee for 1926, will be held at Essex Hall (small hall), Essex Street, Strand, on Monday, February 1, at 6 p.m.

Appointments for the Ensuing Week.—Tuesday, January 19: Guildford and District Gardeners' Association's lecture; Winchester Horticultural Associations' meeting. Wednesday, January 20; Faversham Chrysanthemum Association's meeting; Royal Gardeners' Orphan Fund meeting; Sheffield Chrysanthemum Association's meeting. Friday, January 22: Manchester and North of England Orchid Society's meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Horticultural Society's Garden, Turnham Green.*—Since we last visited this establishment, various alterations have been effected, and others are still in progress. A number of the less important trees have been removed from the Arboretum, which had become too much encumbered with timber, and the result is an evident improvement in its general aspect, as well as more uninterrupted room for visitors at the great exhibitions to promenade in, while there are yet ample trees left for the purposes of ornament, and to afford an agreeable shade from the scorching rays of a summer's sun. In addition to the extensive alterations which took place last spring on the eastern side of the Arboretum, the corner nearest the grand entrance to the grounds at Chiswick House has been much altered and improved, and a new American garden is at present in course of formation on the west side of the kitchen garden. In order to accomplish this, the thicket of miscellaneous trees and shrubs which previously occupied its site, has been removed, except such as were considered of sufficient value to be retained; various excavations have been made, and mounds thrown up, whose sides are planted with evergreens, Yuccas, and other ornamental plants; and, to give variety as well as afford at suitable places views of the general arrangement, the embankments are traversed by paths which are conveniently approached by flights of rustic steps. As it was desirable that the van-road to the exhibition ground should be continued from the carter's yard through the kitchen garden, a bridge, whose supports are flanked by rockwork decorated with Ferns, the lively green hue of whose fronds cannot fail to yield interest at all seasons of the year, has been thrown over the upper portion of the new ground, which is to be entered at this end through masses of Rhododendrons. It being intended that this shall be gay the whole year round, or at least nine months out of the twelve, it will be furnished with plants calculated to effect that end, and if well carried out, as there is little doubt it will be, it will not only form a pleasant retreat at all times of the year, but will also be, for obvious reasons, very instructive. *Gard. Chron., January 18, 1851.*

IRIS GARDEN.

IRIS VARTANII ALBA.

IRIS Vartanii alba has glaucous green, narrow, quadrangular leaves, the apices of which are pale greenish-yellow for about one quarter-of-an-inch in length. This may be a peculiarity of the white variety. The flowers stand about five inches high, and are overtopped by the leaves. The tubes on which they are carried are greenish-white.

The flowers, as large as those of the type, are pure white, except for delicate pale green on the underside of the falls. The style crests are long and narrow, crisped, undulated and very graceful; the standards are narrow and inconspicuous, and there is a narrow, soft pale yellow beard on the upper side of the falls. The sheaths are conspicuous, beautifully striated with green lines. The flowers are sweetly scented.

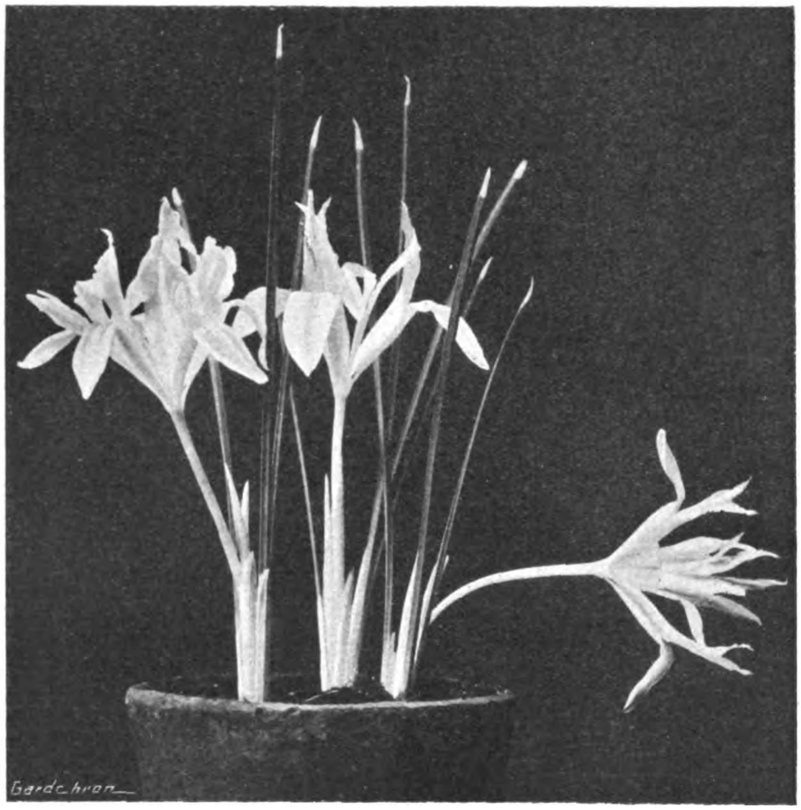


FIG. 18. IRIS VARTANII VAR. ALBA.

The plants illustrated (Fig. 18), have been grown in a pot in a cold frame from bulbs obtained from Messrs. Van Tubergen. It is well worth growing such a delicately flowering treasure in this way for the pleasure the unspotted purity of the flowers and their grace and fragrance give in the gloomy, cheerless first days of the New Year.

At Glasnevin a good-sized patch of Iris Vartanii has lived for several years in well-drained soil at the foot of a wall; grown in such a situation in the climate of Co. Dublin it is a far more satisfactory plant than it is represented to be in the late Mr. Dykes's *Handbook of Garden Irises.*

The leaves of the patch appear in December, the flowers during January and February. Several degrees of frost do not injure nor even tarnish the beautiful grey-blue flowers.

Iris Vartanii is a bulbous-rooted species belonging to the well-known Iris reticulata section. It is a native of Palestine. *Phylis Moore, Rathfarnham, Co. Dublin.*

The Week's Work.

THE ORCHID HOUSES.

By J. Collier, Gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

Zygopetalum Mackayi.—This useful, well-known Orchid blooms at this season. The flower spikes appear in the centre of the young growths, therefore the plant is growing and blooming at the same time, and needs a liberal supply of water at the roots. Being impatient of frequent root disturbance, this Zygopetalum should only be repotted when the compost is exhausted and the receptacle has become too small to accommodate another season's growth. The necessary repotting is best done so soon as the flower spikes have been removed, and the new growths are a few inches high. In order to secure the best results, ample pot room should be afforded ; as a rule, a receptacle two sizes larger than the one the plant has previously occupied will be suitable. Only a small quantity of drainage material is necessary. A mixture of good fibrous loam, Osmunda-fibre cut into short portions, Sphagnum-moss and crushed crocks forms a suitable compost. The plants are liable to attacks of brown scale insects ; these should be dislodged so soon as they are detected, or they will leave brown marks on the foliage. This species grows well in a moist house, with an intermediate temperature ; it should be shaded from the direct rays of the sun at all times. The above remarks apply also to such hybrids as Z. leucochilum, Z. Sedenii, Z. Sanderi and Z. Perrenoudii. The somewhat rare Z. Roeblingianum and Z. rostratum grow best in a moist; shady position in a house having a warmer temperature.

Zygocolax.—The members of Zygocolax are hybrids between Zygopetalum and Colax jugosus, and require similar treatment to that afforded Z. Mackayi.

Calanthes.—Members of the C. Veitchii and C. vestita sections, together with the white C. Harrisii, need a decided rest after the flower spikes are removed. It is necessary to thoroughly harden and mature the pseudo-bulbs, so that when the growing season commences the new growths will start with renewed vigour. Water should be withheld entirely from the roots. and the plants placed near to the roof-glass in a house in which the temperature does not fall below 55°, where they may obtain full benefit of all the sunlight available.

FRUITS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Tomatos.—Tomatos are ripening their fruits slowly. Where the plants are growing in large receptacles they are more under control than if planted out in borders. To obtain a constant supply of fruits the plants should be kept more or less on the dry side, but not to such a degree as to cause flagging. Feed the roots sparingly with liquid manure warmed to the temperature of the house, which should not exceed 60° during the day.

Strawberries.—Strawberry plants that have been prepared for forcing will, at this season of the year, respond more readily to heat and produce finer fruits than those that were introduced into warmth last month. Where a whole house cannot be devoted to the cultivation of this fruit a suitable place is a shelf in the early vinery or Peach house. I generally prepare a double quantity of plants for this second batch ; one batch is started into growth with the early vines while the other is placed on shelves in the early Peach house. The little extra warmth that is required for the vines will hasten the crop quite ten days or a fortnight in advance of those grown with the Peaches. Select good plants with well-matured crowns, and remove all decayed foliage. See that the drainage of the pot is perfect. The plants will require very little water until growth commences, after which they should never be allowed to suffer for lack of moisture at the roots, until such time as the berries are ripening. As a preventive of mildew it will be wise to dip the plants in a prepared mildew wash just before flowering takes place ; see that the specific reaches the underside of the foliage.

Figs.—Trees that are planted in borders may be started into growth to form a succession to those growing in pots to produce the earliest fruits. The night temperature of the house may be about 50°, a little more or less, according to outside conditions, with a rise of 5° during the day. The day temperature of 55° is only given as a guide during cold weather ; with the sun's rays it may exceed this reading with advantage, even when a little air is admitted. The Fig resents hard forcing with artificial heat during the early stages of growth, and it is far better to allow the growths to develop slowly, when there is less risk of the trees casting their fruits prematurely, and they also produce larger Figs. The trees may be syringed with tepid, soft water once or twice daily when outside conditions permit, but this should be done sufficiently early in the day to allow the plants to become dry before night. The borders should be kept in a moist condition ; when water is required at the roots it should be used in a tepid state. Ventilate the house a little on bright days but guard against cold draughts reaching the trees. As the foliage develops less syringing overhead is recommended, for the Fig dislikes a steamy atmosphere when in full growth.

THE KITCHEN GARDEN.

By F. Streeter, Gardener to Major Albert Pam, Wormley Bury, Broxbourne.

Broad Beans.—Make a sowing of a long-podded variety of Broad Beans for the earliest supplies, in boxes one foot wide and four-and-a-half inches deep. The boxes should contain plenty of drainage material and be filled with the following compost : three-parts good loam, one-part leaf-mould and one-part silver sand. Place the seeds two inches apart and one inch deep, make the soil firm and stand the boxes in a cold frame secure from frost. Keep a sharp watch for mice. So soon as the state of the ground will permit, select an open site and thoroughly trench and manure it ready for setting out the plants later.

Dwarf or French Beans. — This valuable vegetable should be forced wherever sufficient room can be found to accommodate the crop. Prepare a number of seven-inch pots and half-fill them with fairly rich soil. Sow five seeds in each pot and cover the former to a depth of one inch. Place the pots in a house having a temperature of 60° at night and 65° by day, rising with sun heat. Water the soil carefully, using tepid water.

Peas.—Undoubtedly the best way to secure early dishes of Peas is to sow seeds at the present time in boxes as advised for Broad Beans, using similar compost. Place the seeds two inches apart and half-an-inch deep and germinate them in a cool fruit house. Watch carefully for rats and mice. Admit plenty of air when the seeds have germinated. The soil of a south border should be trenched and well-manured in readiness to receive the crop when the seedlings are ready for planting out.

Spring Cabbages.—If the spring Cabbages have failed, make a small sowing of an early-maturing variety in boxes in a cold house. These seedlings should be pricked out into other boxes when they can be conveniently handled and planted out in a sheltered border.

Brussels Sprouts, Kales, etc.—See that all decayed and yellow leaves are cleared from these crops, especially after frosty and wet weather. It is an excellent plan to lightly fork the soil along the rows ; this not only sweetens the ground, but keeps it perfectly free from weeds, and adds to the tidiness of the garden.

PLANTS UNDER GLASS.

By John Coutts, Assistant Curator, Royal Botanic Gardens, Kew.

Seed-sowing.—Gloxinias raised from seeds sown during January will form a succession to those started from dry tubers last month. Streptocarpuses are also easily raised from seeds, and they make a fine display the same season. Achimenes, Clerodendron fallax, Gerbera Jamesonii and its hybrids, Naegelias, Saintpaulia ionantha, Tecoma Smithii, Tydeas, Exacum affine, E. macranthum, and Eustoma Russellianum are all choice subjects that should be more generally raised from seeds.

Ipomoea rubro-coerulea. — This beautiful annual greenhouse climber should be raised from seeds sown during January or February. The blue flowers are produced in great profusion and always attract attention. Ipomea Leari, is another beautiful blue-flowered perennial species, which may be raised from seeds or cuttings. This species is seen at its best when planted out in an intermediate or warm greenhouse.

Cyclamens.—Plants that were raised from seeds sown last August and wintered in quantity in pans or seed boxes should now be ready for placing singly in small pots. At this stage a fairly light compost is necessary ; a medium loam with the addition of a little well-decayed leaf-mould and sand, or, better still, some old mortar rubble, is suitable as a rooting medium. In any case, lime is essential for Cyclamens, and in respect of potting soils, liming is, I am afraid, too often neglected. Lime is especially deficient in potting loams cut from old pasture lands. After potting them, the young plants should be placed on a shelf or stage near to the roof-glass in a house having a temperature of 55° to 60°. Afford the roots water with great care until they are well established in the new compost.

Grevillea robusta, Albizzia lophantha and Jacaranda ovalifolia (syn. mimosaefolia).—These are three graceful foliage plants, useful for house decoration and for mixing with flowering plants in the conservatory. Seeds of all of them should be sown at this date in a temperature of 60°. Grevillea seeds often fail to germinate satisfactorily, due, I believe, to covering them too deeply, the thin, flat seeds decaying before they have a chance to germinate. It is a good plan to place the seeds on their edges in a light, sandy compost, or they will germinate successfully when sown in boxes of cocoanut fibre, or fine peat moss litter and sand, standing the boxes in an open propagating case furnished with bottom heat.

HARDY FRUIT GARDEN.

By W. Auton, Gardener to Viscount Elveden, Pyrford Court, Woking, Surrey.

Spraying.—The application of sprays is not a pleasant occupation, but it has proved to be an efficacious means of suppressing both insect and fungous enemies of plants generally, and of fruit trees in particular. It is a task which demands thoroughness, and unless every detail is carried out with careful attention, complete success cannot be expected. Many who use sprays on a large scale prefer to prepare their own fluids from crude chemicals, and where this can be done with scientific accuracy it is the most economical method. For the needs of the average private garden, however, it is infinitely better to use proprietary pastes or powders which simply require the addition of warm water to render them ready for use. Caustic soda washes are largely used as winter sprays, and are highly effective in destroying lichens and hibernating insects. Copper sulphate mixed with lime and procurable in paste form as Bordeaux mixture is a good winter fungicide, while there are recently introduced non-caustic winter washes capable of destroying a variety of insect and fungous pests. These washes have the advantage of not being dangerous to the operator, as some caustic washes are, if the fluid is by any mischance brought into contact with the skin; care should, however, be exercised when using them near growing green crops, or these will be rendered unfit for use. The manufacturers' instructions should be followed implicitly in using caustic soda. All the well-known horticultural chemists may be relied on to supply first-class winter washes with clear instructions as to how to use them, and the high quality of modern spraying machines is well-known. The final word to ensure success remains with the operator, and it cannot be too highly emphasised that thoroughness in application is the greatest factor of all, as if small portions of the trees and bushes are missed and left unsprayed, sufficient stock of the hibernating pests may be left to destroy the whole value of the work done. The actual time of spraying is not rigidly governed by the calendar, but in principle it should be done so late as practicable while the buds are still dormant. As favourable conditions for the operation are essential and not of daily occurrence, it follows that every opportunity should be taken during the next few weeks to complete the work when these favourable conditions prevail.

Apricots.—The pruning of Apricots on south and west walls should not be longer delayed, as the buds will soon begin to swell under the influence of longer days, and the work will be made more difficult. As the Apricot fruits on wood of the preceding year, as well as on spurs on older branches, so many of the young shoots as practicable should be retained. This extremely useful fruit is one of our most difficult hardy fruits to cultivate, and the sudden death of large branches for no apparent reason seems to be beyond the control of growers. The tree grows and fruits with remarkable freedom as a standard in southern Europe without showing this defect, and it is possible that our climate affords too little sunshine for its needs.

THE FLOWER GARDEN.

By F. C. Puddle, Gardener to Lord Aberconway,
Bodnant, Taly-Cafn, North Wales.

Herbaceous Borders.—Many gardeners defer the cutting down of herbaceous plants until the New Year, as the borders have a more furnished appearance in winter, and the browning growths make a good effect during late autumn. These should now be removed, and when weather conditions permit, any necessary dividing of the plants should be done, after which the borders may be top-dressed with short manure, which should be lightly forked in. During mild periods of the winter, slugs do much unseen damage to the dormant growths of herbaceous plants, Delphiniums and Asters being amongst the worst sufferers. At this season the pests work just under the surface of the soil, and if this is carefully raked from the crowns of the plants, they may frequently be discovered feeding upon the young growths. In the case of Delphiniums, the best protection is a band of either plain or perforated zinc placed around the plants. The zinc should be three inches wide so that at least one inch may be pushed into the ground. If plain zinc is used, the upper edge should be cut at frequent intervals, about half-an-inch deep, and the small tongues thus formed should be bent in alternate directions: this forms an impenetrable fence over which no slug can pass. When fixing the collars it is advisable to make sure that no slugs are left in the enclosure, and as an additional precaution a little powdered alum may be sprinkled on the surface of the soil, care being taken that the quantity used is not sufficient to render the soil acid. When collars are not used frequent dustings are necessary, and in such cases lime and soot are the safer remedies, but the first dressing should be applied just under the surface of the soil.

Chinese Barberries.—The deciduous and semi-deciduous species of Chinese Berberis are very beautiful objects when planted singly, but to fully realise their value for garden decoration they should be grouped. A dry bank, such as is often planted with Laurels and other common evergreens, of no particular interest, is an ideal place for a collection of Barberries. In such a position, where they can be planted a little above the general ground-level, their graceful growths (upright in some species and arching in others) are seen to the best advantage. They are beautiful at all seasons, as the verdant green of the young growths in spring is followed during summer by dainty yellow flowers, whilst in autumn a wonderful effect is created by the glorious coral-red berries and the lovely colouring of the foliage which hangs well into the winter; after which the warm tints of the bark of the deciduous and the mature foliage of the semi-deciduous species carry on the interest until the awakening of spring. Barberries may be planted with safety at any time from now up to the middle of March. They are easily raised from seeds which, if sown immediately in gentle heat, and the resultant seedlings grown on under cool conditions, will give plants large enough in late summer for setting out in nursery beds. Three-year-old plants are most suitable for planting in permanent positions. The most attractive garden species are:—Berberis virescens, which is one of the earliest to assume autumn colour, and its warm brown stems are very effective in winter; B. dictyophyllus, with silvery stems and glaucous foliage which turns to a rich tint in late autumn; B. aggregata var. Prattii, together with the typical B. aggregata, two of the best and most effective fruiting species; B. Wilsonae, B. Coryi, B. concinna, B. yunnanensis, B. brevipaniculata, B. Thunbergii and B. subcaulialata (Fig. 19), which gives a profusion of golden flowers that are succeeded by coral-pink berries.

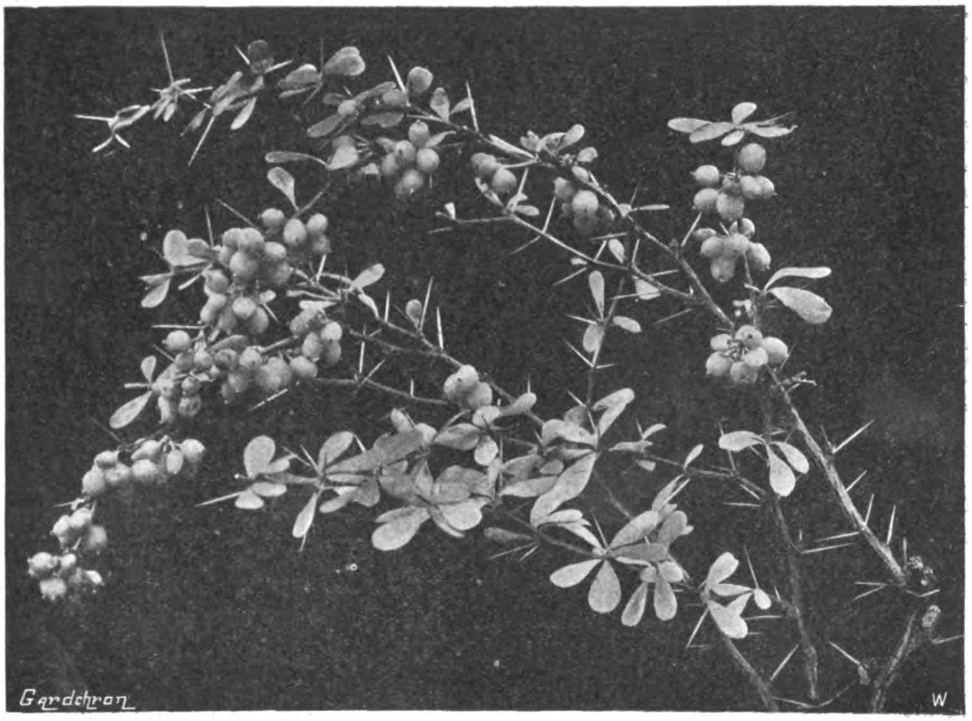

FIG. 19.—BERBERIS SUBCAULIALATA.

FOR NORTHERN GARDENERS.

By A. T. Harrison, Gardener to the Marquis of
Ailsa, Culzean Castle, Maybole, Ayrshire.

Frames.—The occupants of the cold frames, including Violets, the various cuttings put in last autumn, Cauliflowers, Lettuces, etc., should have the soil stirred between them, and if the latter is dry a copious watering should be given when the weather is mild. Do not apply water in driblets at this season, but give sufficient moisture to ensure that the plants will not require watering again for a week or two. Strawberries in pots should never be allowed to become dry, but if the pots are plunged to the rims in ashes they will not only be safe from frost, but not so liable to dry out rapidly.

Cyclamens.—Seedling Cyclamens that have not yet been potted separately should be attended to. If they have been previously pricked out into boxes or pans they should be ready for transference to three-inch pots, using plenty of leaf-mould in the compost. Grow them in a temperature of between 55° and 60° until they are developing freely. Two-year-old plants are now developing their flowers in profusion, and may be given diluted manure water, varying this stimulant with an occasional application of sulphate of ammonia.

Bulbs for Early-flowering.—These are now growing freely, and a succession should be maintained by introducing fresh batches to the forcing pit at regular intervals. So soon as the flowers show colour, the plants should be removed to cooler quarters, where the blooms will remain fresh much longer than if grown in a high temperature. Where plenty of Narcissi are naturalized in the woods, it is worth while digging up a barrowful of bulbs at this time and boxing them for supplying cut flowers. They soon throw up their crop of blossoms and do not seem to be much checked by this treatment; when they are hardened off again they may be replanted in their old quarters. Snowdrops, treated similarly, should have their flowers well-developed before lifting them, when they make a useful addition to the stock of purchased bulbs.

Hippeastrum.—Bulbs of Hippeastrum that have been resting since September should now be examined, and any that are showing flower-spikes should have their roots soaked before re-potting or top-dressing them; if a succession is desired the remainder should be introduced to a moderately warm house in the same manner later. Do not re-pot or top-dress the plants until the tip of the flower-spike is showing, as the operations, if proceeded with too soon, have a tendency to hasten the growth of foliage and retard the flowering.

NOTICES OF BOOKS.

Fungi in Nature.*

Les Champignons dans la Nature, by J. Jaccottet, will doubtless take a prominent place amongst popular illustrated books devoted to the larger Fungi. The only drawback is the price, though this is not exorbitant considering the lavish manner in which the book is produced. The coloured plates are by Paul Robert, fils, and represent 115 species. The Fungi are displayed in their natural habitats, and occupy more of the plate than do those of Bessin in Dumée's well-known atlas. They are mostly all concerned with the commonly depicted species, but include Lepiota gracilenta, Tricholoma panaeolum, T. irinum, Pholiota caperata, Cantharellus lutescens, Hygrophorus marzuolus, H. agathosmus, and Verpa bohemica. The plates on the whole are excellent, but in one or two cases, *e.g.*, Hebeloma crustuliniforme (Pl. 51) and Clavaria pistillaris and C. flava (Pl. 66), there seems a little too much pink. In the body of the text there are forty-seven line drawings to illustrate various points of structure or difference in species; these are by Dr. E. Jaccottet, and serve their purpose admirably.

After a preface by Dr. C. E. Martin, the eminent Swiss mycologist, there is an introductory chapter which deals with such matters as the Fungi in the classics, the way to begin the study of Fungi, a consideration of what one might call newspaper methods of distinguishing between edible and poisonous Fungi—with the obvious conclusion that the *only* way is to be able to identify the species from their botanical characters — cultivation, etc. A general summary of Fungi is then given. Following this there is a consideration of the Agaricaceae and a key to the more common genera. The species are then taken in systematic order. Those which are illustrated are dealt with fully, but allied species are also described, and their distinguishing characters indicated. The other families follow, but are in most instances treated much less fully.

Apart from the description, chief attention is paid to the gastronomic qualities of the species: where edible forms are concerned the best recipes for cooking are detailed; where poisonous or suspicious forms are described the reputed intestinal troubles are given. In addition, however, there is a considerable amount of information. The book justifies its title in that the habitats and seasons of the species are given, and, moreover, in such a way that the impression is gained that the author knows his Fungi in the field. Among points of interest in the work may be mentioned the fact that an attempt to cultivate Mushrooms in the old *caves à bière* at Geneva was unsuccessful—possibly on account of bad ventilation; as is well known, success on the French method has been attained in this country in the old Bath-stone quarries at Corsham, Wilts, and in the quarries at Godstone, Surrey; that in seasons where a very warm period is broken up by storms, Amanita muscaria may have sulphur-yellow stems and gills, with a darker ring becoming even brown; further, with regard to this species the German Swiss—relying on statements from Germany that the Fly Agaric is not poisonous when peeled—have been compelled to withdraw their support to the belief; that formerly the Chanterelle was sold at Geneva by weight, but owing to the market-people keeping them in water and incidentally making them more liable to fermentation and buyers more liable to stomach troubles, a regulation that they should be sold by measure was introduced; Hygrophorus marzuolus is sold at Lausanne in great quantity as the St. George's Mushroom—and Tricholoma cnista var. evanescens, common in the Alps and Jura, has also been mistaken for this species: and that in the Jura, Tricholoma tigrinum causes as much poisoning as Entoloma lividum does in the plains.

As has been suggested above, the paper and printing are excellent. The binding is somewhat ornate and the guard paper has a design with Sepultaria Summeri as a motif—a Discomycetous fungus recorded always from under Cedar, of which it may be one of the mycorrhizal Fungi associated with the roots.

THE MORAINE POT.

Mr. Collingwood Ingram has designed and patented a flower pot which he has personally tried and proved to be a valuable aid to the cultivation of certain plants. As he intends to let the provisional patent lapse he has kindly sent us the following description in order that his fellow gardeners may benefit by the invention.

The "moraine pot" (Fig. 20), is designed to reproduce the conditions required by plants in Nature. It is a well-known fact that in the alps (and to a slightly lesser degree, in the lowlands also) during the summer months, when growth is at its height, practically all plants derive their root moisture from below. This is essentially the case in moraines where melting glacier water is continuously soaking through the subsoil and supplying the roots with a constant flow of subterranean moisture.

It is claimed for this pot that these conditions are reproduced artificially with the minimum of labour. By its use, although the plant is getting as much water as it requires, the uppermost layer of soil need not be unduly wet, and the danger of damping off is consequently reduced. The surface soil is never disturbed by heavy overhead watering, which is, of course, a very important factor where small seeds are concerned and when tiny plants are commencing to grow.

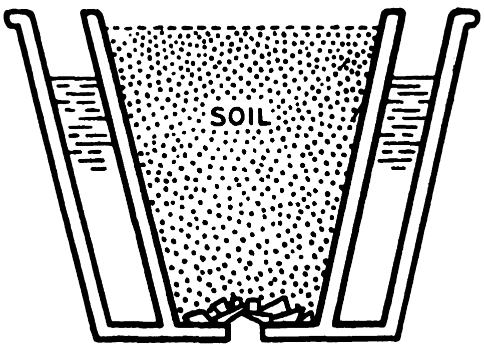

FIG. 20.—A MORAINE POT.

The "moraine pot" is supplied with an outer cover or water jacket which should be filled periodically with water—once or twice a week in summer. The water gradually percolates through the porous walls of the inner pot, thus keeping the soil cool, moist and fresh. A hole at the bottom of the inner pot ensures perfect drainage and keeps the soil sweet. The "moraine pot" is not only very valuable for the cultivation of "difficult" alpines, but is also a perfect medium for the propagation of plants from seeds and cuttings. The percolation and, therefore, the amount of moisture the soil in the inner pot receives, may be regulated by placing coarse or fine sand with the water in the surrounding jacket.

WINTER FLOWERS.

The number of plants in flower at midwinter out-of-doors in the present season is much fewer than has been the case in recent years, but this is not surprising seeing that the weather has been much more wintry than usual. Whatever the weather conditions, however, the growth of vegetation does not entirely cease, and on New Year's day I noted the following interesting list of plants in flower, most of which are by no means uncommon at this season:—Arbutus Unedo, A. Andrachne, A. hybrida, Alyssum maritimum, Cheiranthus Allionii, Chimonanthus fragrans, Dendromecon rigidus, Erica codonodes, E. vagans, several varieties of E. carnea, including alba, rubra, King George and darleyensis, Gentiana sino-ornata, Grevillea rosmarinifolia, G. sulphurea, Hamamelis virginica, Helleborus nigra, Iberis gibraltarica, Iris unguicularis, Lonicera fragrantissima, Lupinus polyphyllus, Lithospermum prostratum, Prunus sulhirtella, Polygala Chamaebuxus, Primula Winteri, Rosmarinus officinalis, Viburnum Tinus, and V. macrocephalum. Occasional flowers in quite good condition of Roses and Chrysanthemums still remained, while a moderate sprinkling of flowers were to be found on Aubrietias, Polyanthuses and Violas.

Amongst native plants, several of which bore seed pods approaching maturity, were noted:—Bellis perennis, Capsella Bursa-pastoris, Cerastium vulgatum, Claytonia prefoliata, Lamium purpureum, Matricaria inodora, Potentilla verna, Senecio vulgaris, Stellaria media and Taraxacum officinale. *W. Auton, Pyrford Court Gardens, Woking.*

ALPINE GARDEN.

VINCA HERBACEA.

It is not easy to understand why the subject of this note should so seldom be seen in the average garden, for it is a species of peculiar distinction and unquestionable merit. The only explanation which I can suggest is that, being entirely herbaceous, the plant is apt to get forked out and lost. This fate must certainly often befall many of the rooted runners; which became established within a couple of feet or more of the parent plant. This having happened too frequently in my own rock garden, I am now giving V. herbacea a considerable space to itself, save for some dwarf Daffodils and other bulbs, in the open woodland, where it can spread at will, and, I hope, cover the ground in spring and summer with its long succession of blue, starry flowers.

V. herbacea is quite reasonably hardy, but it seems to prefer a friable, well-drained soil with full sun. *J.*

PRIMULA SIEBOLDII.

I have frequently been confronted with the question: "Why has this Primula such a short life, seeing that it is described as 'hardy'?" In numerous instances the plants lived for several years, attained a good size and then disappeared without any apparent reason. One cause of losses, though not the only one, has been the destruction of plants in winter when they were at rest. The crowns are often covered by leaves and soil in winter, and if left unlabelled run a serious risk of being destroyed in the periodical cleaning up and forking of the soil, even in a rock garden where the small hand-fork is employed. To prevent this risk, a good permanent label is the obvious remedy.

But I know that this does not account for the majority of the losses, which are as common among old, established plants with numerous crowns as with small specimens, which are most liable to suffer from disturbance. We must seek for something else in the case of the old plants.

Sometimes a little top-dressing in autumn will save the plants. In course of time soil sinks or is washed from the crowns and roots and they are left too much exposed. This is responsible for a good number of the failures. On the other hand, these losses occur among plants that are top-dressed, and I am inclined to attribute many of the deaths to drought, especially as they frequently occur in spring, when dry weather is so injurious to plants making their growths.

I have come to the conclusion that P. Sieboldii and its varieties require a cool, rich, moist soil, and that drought at any season is inimical to them and leads to by far the majority of the losses. Mr. Farrer recommended such a soil for P. Sieboldii; his cultural experiences were largely gained in growing his plants in a cool district with a heavy rainfall. The casualties among pot plants, which may be kept more under control as regards watering, etc., are very much smaller than those in the open, and unless we can attribute these to want of hardiness, which I am not prepared to do, we ought, I think, to come to the conclusion that most of the losses, though not all, are due to insufficient moisture and too warm positions.

---

* *Les Champignons dans la Nature*, by J. Jaccottet. Delachaux and Niestlé S. A.; Neuchatel. 76 coloured plates, 47 text figures, 243 pages. Price 30 fr.

The value of this Primula surely justifies some discussion on such points, and will be sufficient apology for endeavouring to elicit the views of other cultivators on this fine old plant with its delightful varieties.

NIEREMBERGIA RIVULARIS.

FEW plants from the River Plate are hardy enough to succeed in our climate, and doubts have even been expressed regarding the prudence of exposing Nierembergia rivularis, sometimes called the Cup Flower, to the rigours of our winter. This doubt has been fostered by the unhappy experience of some who have purchased scraps of plants so over-propagated that they were unable to grow with the freedom such a plant requires for success.

To see a carpet of this Nierembergia, with its glossy leaves, covering the ground and thickly spangled over with its pearly-white flowers, is to have the delight of admiring one of the pictures of floral charm which imprint themselves indelibly on the mind of the observer. A sunny, slightly sloping bank of sandy soil, full of moisture from below all the summer, is an ideal place in which to grow Nierembergia rivularis; the next best situation is a broad, sunny rock garden pocket made water-tight to within six inches of the surface of the soil, with stones and gravel beneath and sandy soil above, with the pocket filled with water during the summer, but with an outlet provided to drain away the water during the resting time.

Even those who cannot secure these conditions may grow it in a well-drained pan of sandy, gritty soil, in a frame during the winter, and in spring place on an inverted flower pot in a pail of water, filled to about an inch over the base of the pan. A friend of mine cultivated N. rivularis in this way for very many years, and, artificial looking as were its surroundings, he and his friends derived much satisfaction from its beauty, as it displayed its large white flowers above the glossy foliage. Nierembergia rivularis is easily increased by division in spring. *S. Arnott.*

CHRYSANTHEMUM ALPINUM.

THIS pleasing alpine comes from a fairly high altitude, and the illustration (Fig. 21), shows it growing on the Gruben Alp. It loves moisture about its roots, therefore it is better suited to the moraine than the higher and drier parts of the rock garden. Possessing attractive foliage and producing a goodly number of glistening white flowers, this species is well worthy of cultivation. Not all who have grown it have been successful with Chrysanthemum alpinum, but those who have failed should remember its liking for moisture—not stagnant moisture—and sunshine, and the desirability of providing it with a top-dressing of gritty soil in spring. Protection of the new growths from the terror that gnaweth in darkness—the slug—should also be borne in mind.

HARDY FLOWER BORDER.

ORNAMENTAL GRASSES.

FEW gardeners are aware of the wealth of beautiful hardy grasses of an ornamental character which is available for making the flower border additionally attractive at all seasons, even in winter. It has been a revelation to many to know that a grass garden in itself is possible, as demonstrated at exhibitions in recent years.

For the flower border, or as an edging to beds and borders, the following are amongst the most useful and attractive :—

Avena sterilis (the Animated Oat) is an annual less than two feet high, with drooping panicles of large spikelets, which, when ripe and dried, will, if placed on the warm hand, often move by the contraction of the hairs by which they are covered, hence the popular name.

The species of Briza (Quaking Grasses) are exceedingly handsome annuals, growing from one to one-and-a-half foot high, with pretty, heart-shaped heads in panicles. These grasses are much prized for the making of bouquets. B. maxima, the large form, and B. gracilis, the smaller, are both very ornamental plants.

Eragrostis elegans (Love Grass) is a vigorously growing annual, producing numerous branching inflorescences of a rich purple colour. The plant is very showy; it requires plenty of room.

Stipa pennata (Feather Grass), is one of the most beautiful and graceful of perennial grasses, growing two to three feet high. The numerous undulating inflorescences are covered with extremely fine silvery hairs, or down, which render them most charming subjects in the herbaceous border. The "feathers" are much prized for the making of bouquets in winter.

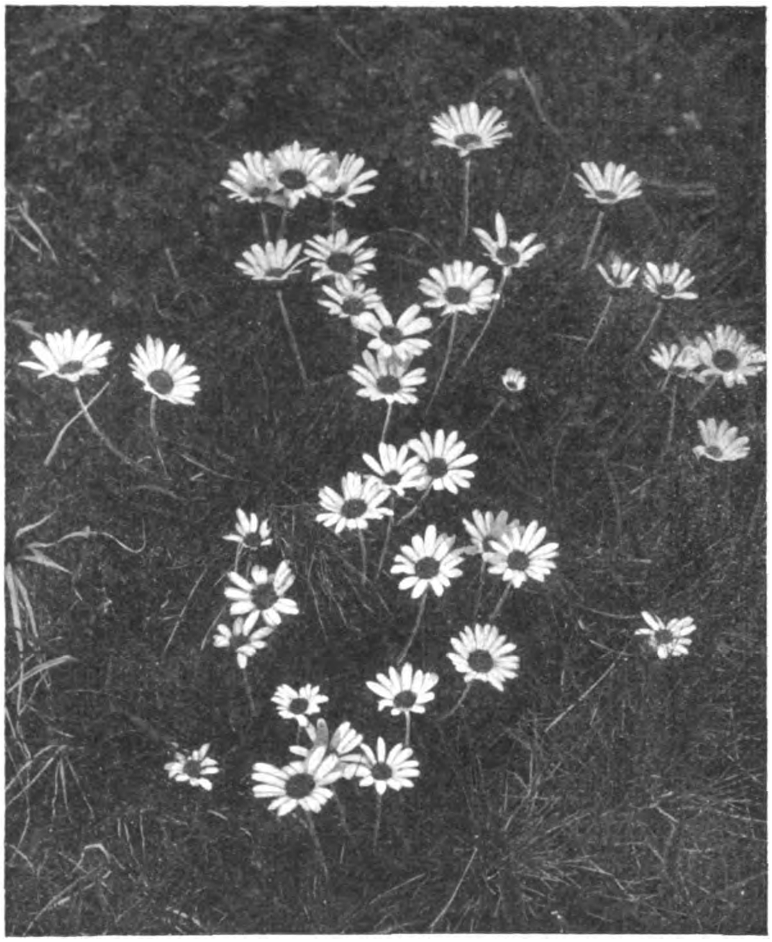

FIG. 21.—CHRYSANTHEMUM ALPINUM.

Bromus brizaeformis (Brome Grass) is the best of all the Brome Grasses. It is a biennial. The best results are obtained from seeds of this grass sown in July and early August. The plant grows about two feet high. The large, graceful drooping heads, like those of Quaking Grass, are exceedingly ornamental, and much prized for cutting for winter decorations.

Lagarus ovatus (Hare's Tail Grass) is a showy annual, growing from one to one-and-a-half feet high, and producing large, showy plumes in downy tufts.

Zea Mays japonica fol. variegata (Variegated Maize) is, perhaps, one of the most valuable and decorative of all grasses, having tall stems three feet to four feet tall, and broad variegated foliage, beautifully striped with cream and white on green. The variety comes true from seed. Few grasses could be better adapted for planting near the seaside, or for lighting up the herbaceous and shrubbery borders. This half-hardy annual requires to be sown in February or March in gentle heat, the seedlings hardened off and planted out in May; or seeds may be sown outdoors in May or June, in a light, rich, warm soil. *W. Logan.*

GILLENIA.

GILLENIA trifoliata is not so commonly grown as it deserves to be, for in addition to being a very pretty garden plant, its flowers are acceptable in a cut state, possessing the quality of lightness. One other species, G. stipulacea, is known to cultivation, but this is rarely seen in gardens. It produces white flowers in June on stems about two feet in height; the leaves are lanceolate and deeply incised.

G. trifoliata has red to white flowers in panicles the calyces becoming red after the petals have fallen. The plant grows to a height of from one-and-a-half foot to two feet, and was introduced from the northern United States in 1713. It is figured in *Bot. Mag.*, t. 489, under the name of Spiraea trifoliata. *Ralph E. Arnold.*

PHORMIUM ALPINUM.

FOR gardens or watersides, where the commoner Phormium tenax would be too large, the dwarf species, P. alpinum (Hookeri) makes an excellent substitute. The leaves of this species are barely half the height of those of the taller one, and often do not exceed three feet. They are sword-like, stiff and upright, green rather than glaucous, and the pale-yellow flowers are borne on stems at least twice the height of the leaves.

P. alpinum appears to be absolutely hardy, hardier, that is, than P. tenax, and this fact will appeal to those who have failed to grow the latter on account of climate. Moreover, being so much shorter and stiffer than its congener, P. alpinum is well adapted for windy situations. Indeed, I have often seen its leaves entirely uninjured by wind which has made shreds and ribbons of those of the larger species. *J.*

ORCHID NOTES AND GLEANINGS.

LAELIO-CATTLEYA SANTA CLAUS.

THIS handsome cross between L.-C. Soulange and L.-C. St. Gothard appeared in the nurseries of Messrs. Stuart Low and Co., Jarvisbrook, Sussex, who sent it to me for examination, the infloresence coming as a pleasant surprise on Christmas Day.

Although the flower is produced on a small seedling, it is large and finely proportioned; the sepals and broad petals are coloured light mauve with pearl-white ground showing between the veining. The base of the lip is coloured like the petals, and the rest is chrome-yellow, with thin dark lines inside. The broadly-expanded front is ruby-purple with narrow white margins, the front portion being much undulated and fringed in several folds.

The wavy-edged development in this and some other of the finest Laelio-Cattleyas, raises a question of how this is produced, which Orchid hybridists would find interesting to follow. None of the showy Cattleyas which are in the composition of the hybrid under notice is noted for a much frilled lip, and the Laelias in it are distinctly plain edged.

Cattleya Dowiana is the first step in this case, and the inference is that in the successive crossing of dissimilar species, the nerves and veining of the lip in their progeny become more numerous and ample, and this produces the folded undulation in the front of the lip. Such subjects give great opportunities to the cultivator, for under good culture the lip expands and its beauty intensifies in a great degree, the folds opening laterally in response to the firmer substance of the well-defined blade. *J. O'B.*

ZYGOPETALUM MACKAYI.

ORCHIDS that produce bold spikes of flowers during the winter are always valuable, and the flowers are especially appreciated when they are distinct in colour and shape. The cut spikes of this Orchid adapt themselves to indoor decorations admirably. This species, was introduced so far back as 1826, from Brazil, therefore, it has been in cultivation for a century, and to-day is in demand for both export and the home market, which illustrates the changes which take place even in the uses of flowers.

Being one of the easiest of Orchids to manage, there is no reason why its cultivation should not be attempted in gardens even where there are no pretensions of growing Orchids generally. It is often found succeeding luxuriously in a house where no other Orchid is grown. Two plants shown at the R.H.S. meeting on December 13, 1892, had one-hundred-and-sixteen large flowers collectively.

The type species, its varieties crinitum and intermedium, vary only in size and colour, and for practical purposes may be treated alike. Pots are the best receptacles for these strong-growing plants, and as they are robust rooters they should be given a fair amount of pot room. The compost should consist of equal parts of fibrous peat, loam, and Sphagnum-moss, with sufficient fine crocks added to keep the compost sweet and open. It is advisable to remove all the earthy particles from the peat and loam, as there is the danger of the fine soil washing down to the drainage and blocking it.

The roots are of a soft, succulent nature, and will not live in a sour compost; hence the necessity of a clean, open rooting-material. Repotting should be done annually, at the time the new growths begin to produce roots.

Coming from the same district as Laelia purpurata and some members of the Cattleya family, the cultural treatment, as regards temperature and ventilation, is essentially the same, with the exception that the Zygopetalum will not withstand the same amount of sunshine as either of the other Orchids mentioned, therefore, a shady position should be selected in a house where an average temperature of about 60° is maintained. The supply of water should be constant during the growing season; strong, healthy plants are rarely at rest, but when the pseudo-bulbs are completed much less moisture will suffice. The usual precautions are necessary in regards to the application of water to newly-potted plants.

There are several hybrids which have been raised from the type species and its varieties, which are a decided improvement on the original plant, and comprise a most useful and beautiful race of winter-flowering Orchids. They include such useful sorts as Z. Blackii, Z. Perrenoudii, Z. leucochilum, Z. Sedenii, and Z. Sanderi.

Zygopetalum Mackayi also enters into the parentage of several members of the bigeneric hybrid, Zygocolax, which is also a useful family of Orchids on account of the unusual colour of the flowers. *J. T. B.*

TREES AND SHRUBS.

BERBERIS AQUIFOLIUM (MAHONIA).

THIS very common plant is not in great favour with lovers of hardy shrubs, but if given the treatment suggested below, it will become an object of beauty throughout most of the year. Do not allow it to flower in spring, but cut it hard back and remove all old leaves, leaving it trimmed to a regular shape. During April and May the young growths will be attractive and conspicuous, first a bright green, changing to scarlet, and gradually assuming the usual brown tint as the summer advances. Again, about August, remove all the tips of the branches; this will cause growth to break again before winter, and those young growths will remain a rich brown red—instead of the usual dull brown or green of the older leaves—through the winter. After a hoar frost, I know of no shrub more beautiful, when every leaflet has a well-defined margin of glistening silvery white, as if it had been painted by a clever artist. When left to develop in its own way, perhaps no shrub grows more straggly and untidy; its yellow flowers are not welcome when Daffodils are blooming, and very few folks admire its mournful berries; moreover, old leaves become dirty, ragged, and much rubbish collects around the stem bases.

COTONEASTER HUMIFUSA.

THIS is a beautiful, creeping, evergreen shrub that is apt to be overlooked when planning a rock garden. It always attracts attention when grown, by the manner in which it spreads in an embracing attitude over large stones, where it seems thoroughly at home. When covered with its scarlet berries it forms a conspicuous object of beauty in the rockery, resembling Nertera depressa of the greenhouse. Its habit of growth is downward, therefore, it should be planted rather high up on the rockery or it will soon run over the path. It is doing well here on a northern aspect, in soil which is mainly decayed vegetable matter. *R. Gardner, Heywood Gardens, Cobham, Surrey.*

AUCUBA JAPONICA MACULATA.

MR. COPLEY, p. 6, evidently regards the variegation or maculation of the leaves of the above plant as a guide to its sex, for he states, "Whenever I have examined the flowers of a variegated spotted Laurel they have been found to be staminate. Whenever I have examined the flowers of the green form they have been pistillate." With a wider experience, he may find that this is not always the case. A few facts will, perhaps, make the case clear. A. japonica was introduced in 1783. Bean states in *Trees and Shrubs Hardy in the British Isles*: "This first plant was the well-known yellow spotted form (maculata), and a female, but owing to the absence of pollen it was not until Fortune, sixty years later, introduced the green-leaved male plant, that the great beauty of the Aucuba as a berry-bearing plant became known. Now, both green and variegated plants of both sexes are common."

My first acquaintance with A. j. maculata dates back to 1878. The female form described by Mr. Bean was then very commonly planted in shrubberies. So far as I can remember it never bore fruit. Fortune's green-leaved male, although introduced thirty-five years previously, would not appear to have been planted generally. When I went to Messrs. J. Veitch and Sons' nursery in 1887, a dwarf, green form of Aucuba, beautifully berried, was being sold in pots as a market plant. About twenty-five years ago, I first noticed an occasional berry on large bushes of A. j. maculata; as there were no male plants on the estate, I assume they were pollinated by insect agency. Later, I purchased for my employer, several hundred green Aucubas to plant in shady places. Among them we have many types and both sexes, and since their advent the old A. j. maculata has borne fruit freely. Though the flowers on this old form are pistillate, it is, as I stated before, not impossible for a spotted-leaved male form to have been raised, indeed, Mr. Bean states plainly that "variegated plants of both sexes are common." *J. Comber.*

PHYLLODOCE.

OF the genus Phyllodoce (Bryanthus) there is no more beautiful species than P. empetriformis, the best known and most easily-grown member of the family. It is a low, semi-prostrate shrub, seldom rising much above nine inches, with deep green, glossy, Heath-like foliage.

The flowers, which appear in April or May from the leaf-axils at the tips of the tufty twigs, are pitcher-shaped, about a quarter-of-an-inch long, and of a clear rose-crimson, for which the rather dark foliage is an admirable background. The blossoming season extends onwards into summer, and there is often another crop of blooms in autumn. It is remarkable that a dwarf shrub of such outstanding merit should so seldom be seen in gardens, for it will grow well in any moderately cool loam in which Heaths prosper, and it does not object to a little shade.

Like the foregoing, P. Breweri is a native of western North America, where it is found growing on high altitudes of the Sierra Nevada, It is as hardy as P. empetriformis, but perhaps not quite so adaptable in gardens, being a little more impatient of drought, and a great sun-lover. It bears a close resemblance to its congener in stature, foliage and habit, but can at once be distinguished by the flowers, which are produced in May and June in a terminal raceme instead of singly. Individually, the blooms are very lovely, the corolla, which opens flat, being a lively shade of rosy-crimson.

P. coerulea (syn. Andromeda coerulea), a high alpine of many parts of the northern hemisphere, including Scotland, is a dwarf shrub of about six inches, with the same linear leaves and tufted, lowly habit.

The flowers, which appear singly, or in small umbels, are pitcher-shaped, bluish-purple and about one-third-of-an-inch long. P. coerulea is always rare, both in gardens and nurseries, probably because it is a difficult plant to accommodate in English gardens with that coolness, not merely of soil but of atmosphere, which its lofty mountain homes provide and without which it is never very happy. I find that it does fairly well in a gritty soil freely mixed with old, black leaf-mould, the bed having a slight slope to the north-west.

Phyllodoce aleutica, if one may be guided by its name, comes from the Aleutian Islands of Alaska. It is a very uncommon species, probably rarer than the preceding, but with us it has so far proved successful in such conditions as I have described above. P. aleuticus is in foliage and habit much like the rest of the family, but the leaves, which bristle so abundantly on its upright twigs, are a peculiarly bright and cheerful green. The flowers are urn-shaped and pure white. *A. T. Johnson.*

INDOOR PLANTS.

PITCAIRNIA CORALLINA.

THIS extremely interesting Bromeliad is considered to be "the finest for decorative purposes of all the seventy known species of the genus" Pitcairnia. A native of New Grenada, it was first introduced to cultivation about 1870, by M. Linden, of Brussels, who appears to have received it from the Andes of the province of Choco, in New Grenada. The honour of first flowering it in Europe belongs to Baron Rothschild, in whose garden at Ferrières it bloomed in 1874. Many years ago Sir George Macleay had a fine collection of indoor plants at Pendell Court, near Bletchingley, and here it produced the inflorescence which is figured in *The Botanical Magazine* (t. 6600), of 1882.

There appears to be no great difficulty in growing and flowering this species under cultivation, provided the plant receives plenty of heat and moisture, such as a stove provides, and is well established in a pot. In March of 1925, a specimen in the Water Lily house, in the T. range, at Kew, bore several large inflorescences, and as the numerous flowers, as well as the peduncle, are of a brilliant scarlet red colour—brighter and less crimson than in the *Bot. Mag.* illustration—it proved a great attraction.

Pitcairnia corallina is a stemless plant, with leaf blades two to three feet long, each on a stout petiole a foot long. Although the leaf-blades are not spiny, there are decurved, horny spines on the margins of the petiole. The leaves are plicate, about three inches wide, and very much like those of Curculigo recurva, a once popular foliage plant. The inflorescence is heavy, which is probably the reason why the peduncle is usually abruptly recurved, thus presenting the raceme in a pendulous or more or less horizontal position. The raceme figured in our Supplementary Plate was about fifteen inches long, and produced at Kew. The illustration admirably depicts the flowers and their arrangement on the raceme, on a reduced scale, but colour is needed to convey an adequate idea of the brilliance of the flowers. The latter, in addition to the stout, vivid, scarlet-red sepals, have petals which extend for a couple of inches beyond the sepals—as shown towards the base of the raceme in our illustration—and equally long stamens, bearing anthers half-an-inch long on white filaments.

During the past year, Pitcairnia corallina flowered at Kew in the Aroid House, near the main entrance to the Royal Botanic Gardens, as well as in the Water-Lily house (see *Gard. Chron.*, March 28, 1925, p. 222).

JACOBINIA PAUCIFLORA.

A SMALL batch of the above plant makes a pleasing display in a warm greenhouse after mid-December and on through January, the exact period of flowering varying a little according to the cultural treatment, and whether all the plants have been kept in the same temperature.

To obtain good flowering specimens in one season, grow three plants in a five-inch pot, and the next year, should larger specimens be required, these plants can be transplanted to eight-inch pots. One plant, however, when well-grown, will fill an ordinary forty-eight-sized pot. A small amount of feeding is beneficial when the buds are being formed; feeding is also necessary for plants that have not been potted on and are root-bound. The propagation of this plant is fairly easy from cuttings inserted in spring.

The scarlet and yellow tubular flowers are attractive and appreciated, and provide a change to Chrysanthemums and Ericas. Like these latter plants, the Libonia makes a good subject for house decoration. I have kept the same plants for a fortnight in a large window of a drawing-room.

The nomenclature of this plant is somewhat confused, for no two authorities, so far as I can discover, give the same generic name. *Johnson's Gardener's Dictionary* uses the name Libonia, under which it is known in gardens, and states that the plant was named in honour of M. Libon. *Thompson's Gardeners' Assistant* (1901 edition) refers it to Jacobinia, and mentions four or five species, but does not include floribunda. And what makes the matter more complex is the fact that the colours of the varieties mentioned in Thompson's book are undoubtedly meant as self-colours, whereas the flowers of J. pauciflora are bi-coloured. *C. Turner, Ampthill Park Gardens.*

CANNAS.

THERE are many beautiful varieties of Cannas which are invaluable for conservatory decoration, especially when their long season of flowering is considered, for they bloom continually through the summer and autumn.

They are especially useful when grown in small pots for furnishing the plant stages; for this purpose a start should now be made with an early batch. Select strong rhizomes and after trimming off the dead roots and decayed portions, place them singly in four-inch pots; at this stage the rhizomes should be barely covered.

Cannas are gross feeders, and a rich compost is necessary. They also need plenty of heat and moisture. Start them into growth in a house having a temperature of 60° to 65°. At this stage great care should be exercised in affording water to the roots, as they are very apt to damp off before they make new roots and start into growth. This trouble is not so apparent with strong, fresh, home-grown stock, but purchased plants often prove troublesome in this respect, due, no doubt, to the rhizomes being overdried.

I find that Cannas winter best when stood on a moist, earthen floor.

When the plants have well-filled their pots with roots they should be transferred to six-inch pots in which they may be flowered. The compost should consist of a good, rich loam, mixed with well-decayed farmyard or old Mushroom bed manure, and sufficient clean, coarse sand to render the soil open and porous. When cultivated in this way, growth should be restricted to one strong shoot; when the plants have well filled their flowering pots with roots, feed the latter liberally.

The types suitable for growing in this way are represented by such fine varieties as J. B. Van der Schoot, The President, President Meyer, Fiery Cross, Oiseau de Feu, Victorie, R. Wallace, and the Gaikwer of Baroda. Where large specimens are required for furnishing beds in the conservatory, three or four rhizomes should be started in six-inch or seven-inch pots, afterwards shifting them into ten-inch pots; or, if desired, they may be placed directly in their flowering quarters, in which case very little water should be given them until they start into growth. *J. Coutts.*

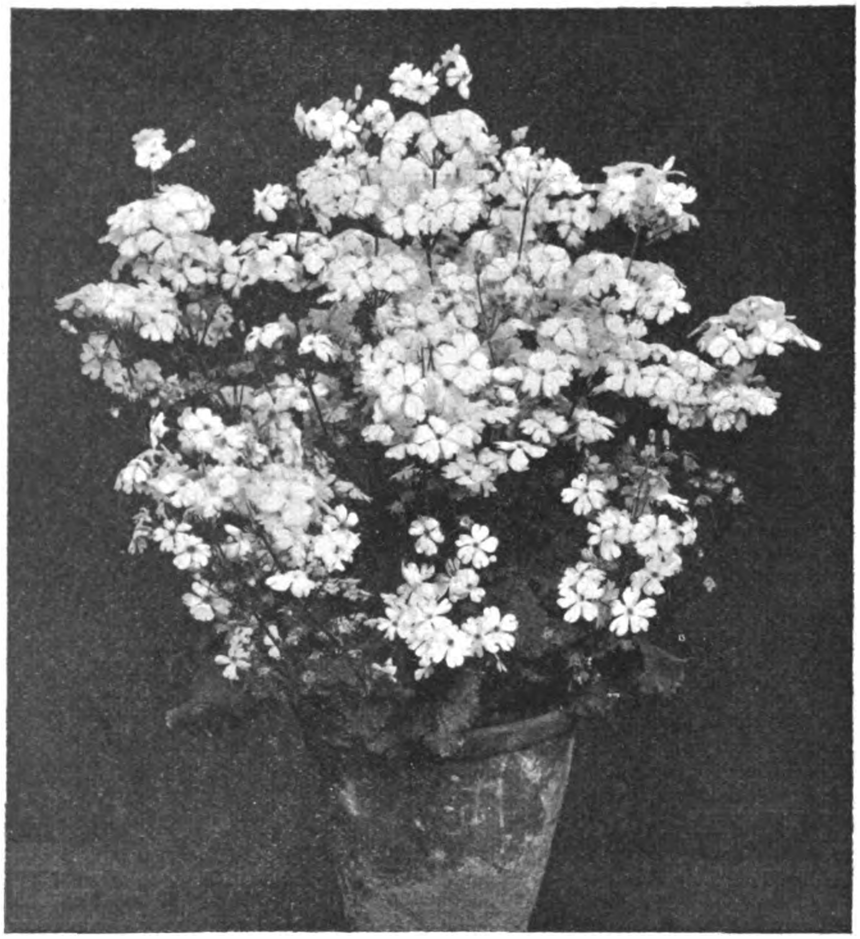

FIG. 22.—PRIMULA MALACOIDES VAR. GOLDEN EYE.

PRIMULA MALACOIDES VAR. GOLDEN EYE.

AMONG the several varietal forms of the popular Primula malacoides the variety named Golden Eye is quite distinct and as free-flowering as the type. The illustration (Fig. 22) shows how shapely and elegant a well-grown plant can be.

To freedom of flowering and neat habit of growth must be added two other excellencies, i.e., pure white flowers and a small golden eye.

This variety emanates from Messrs. J. Carter and Co., Raynes Park, who exhibited specimens at the meeting of the Royal Horticultural Society held on April 11, 1925, when an Award of Merit was made in its favour.

When it becomes better known P. malacoides var. Golden Eye cannot fail to become a popular plant for the decoration of the cool greenhouse and conservatory.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.

Urgent Communications.—*If sent by telegraph, these should be addressed "Gard. Chron.," Rand; or by telephone, to Gerrard, 1543.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

PETER COLLINSON: A QUAKER HORTICULTURIST.

IT is pleasant to reflect that this very interesting biography* comes from the pen of one who lives on the very spot where Peter Collinson had his second garden, and where even to this day are to be seen some of his trees, including the Cedars of Lebanon and the Portugal Laurels, and the remains of his garden walls. A master of Mill Hill School, and its historian, Major Brett-James, is admirably qualified for the task, and has succeeded in giving us a very convincing portrait of that excellent eighteenth century horticulturist, supplemented by an account of the times in which he lived and the many friends he made during his long and useful life. Nevertheless, many will no doubt demur when they find Collinson referred to as "one of the leading botanists of the period"; and, further, when they meet the statement that John Bartram became "the finest botanist of his time." Whilst it is true that the word "botanist" was sometimes applied rather loosely in the eighteenth century, its distinction from "horticulturist" was well-defined even then, as may be seen by referring, for instance, to Linnaeus's *Philosophia botanica*. That Collinson was a lover and promoter of botany and natural history generally, is admitted, and he earned well-merited recognition at the hands of Linnaeus when the genus Collinsonia was founded; that John Bartram, celebrated as a collector of American plants, had some considerable knowledge of botany, is also granted; but can the laudatory phrase used by our author in either of these cases be fully justified? One would rather look upon Collinson as a very notable example of a man who had loved natural history all his life, and who did all in his power to encourage it; who had lived a peaceful life with his mind attuned to natural beauty, but without any desire to systematize his knowledge; and whose general outlook on men and affairs was always that of a benevolent and well-balanced mind.

In the present work the fullest available details of the Collinson family are brought together for the first time. At least from the fifteenth century it appears to have been located in Westmoreland: the earliest name mentioned being that of John Collinson, of Kendal, in the year 1409. However, Peter Collinson was a Londoner by birth, being born on the 28th January, 1693/4, "in a house opposite Church Alley, St. Clement's Lane." From his earliest years he was a lover of flowers: "Being sent at two years old to be brought up with my relatives at Peckham, in Surrey, from them I received the first liking to gardens and plants. Their garden was remarkable for fine cut greens, the fashion of those times, and for curious flowers." With the exception of one trip to the Netherlands in early manhood, and an occasional visit to some part of England, he appears to have pursued his quiet, useful life, gravitating between his business house in "Gracious Street" (Gracechurch Street), where he and his brother were cloth merchants, and his "little cottage" at Peckham, then a pretty village. In 1749 he moved to Ridgeway House, Mill Hill, where he had wider scope to carry on his planting of exotics. No trace can now be found of his Peckham garden, which was said by Peter Kalm, who visited it in 1748, to be "a beautiful little garden, full of all kinds of the rarest plants, especially American ones." It is generally presumed that Linnaeus, during his short visit to England in 1736, saw Collinson in his Peckham garden; although, in a letter to Linnaeus in 1765, Collinson wrote: "I am thinking what a many and variety of occurrences have happened since I saw my dear Baron at my house in London." As Collinson states that he was away most of the time Linnaeus was in England, it seems not improbable that the latter went to the business house in Gracechurch Street, perhaps in the company of Pastor Tobias Björk, with whom Linnaeus lodged at his house in Ratcliff Highway; and, in fact, in several of the letters to Linnaeus, Björk is mentioned as a mutual friend.

PETER COLLINSON. F.R.S. S.A.S. ACAD. REG. BEROL. et SVEC. SOC.

PETER COLLINSON.

(From *Nichols' Literary Anecdotes*.)

All this is interesting in connection with a tradition that Linnaeus planted two Cedars at Mill Hill to commemorate his visit there. Major Brett-James is inclined to allow some weight to this tradition, and brings forward some evidence that Collinson was allowed by his father-in-law, from whom he inherited Ridgeway House, to plant things in the garden several years before 1749; and, further, that the Linnean Society "held a field meeting and picnic in the grounds of Mill Hill School" in 1835, to commemorate Linnaeus's planting of the Cedars. The latter event seems also of the nature of a tradition as the Society's records contain no reference at all to it; and it must have been an unofficial gathering of a few enthusiastic Fellows. One might suppose that Collinson, visited by Linnaeus at his house in Bishopsgate Street (where he no doubt kept a small museum), found it more convenient to take his visitor to Mill Hill than to Peckham; and thus lend some more weight to the tradition. However, a tradition remains a tradition until some substantial evidence is brought forward to change it into history.

Collinson's letters to Linnaeus, covering many years, enable one to see how valuable a friend he became. As a unique source for obtaining new American plants and seeds, Linnaeus owed a debt to Collinson; and if Collinson's letters were not those of a scientist eagerly discussing technicalities, they were no doubt much appreciated for the warm friendship and the love of Nature they expressed. The purchase of Patrick Browne's herbarium of Jamaican plants alone was a service which showed, not only Collinson's business acumen, but also his appreciation of what its botanical value would be to Linnaeus. In several of these letters are passages which show in a charming way the poetic side of Collinson's mind; "How ravishing to see the swelling buds disclose the tender leaves!" "How delightful to see the order of Nature! Oh, how obedient the vegetable tribes are to their great Law-giver! He has given this race of flowers a constitution and fibres to resist the cold. They bloom in frost and snow, like the good men of Sweden." He also tells Linnaeus: "my favourites [are] the great tribe of Narcissuses," which, though quaint, shows excellent taste.

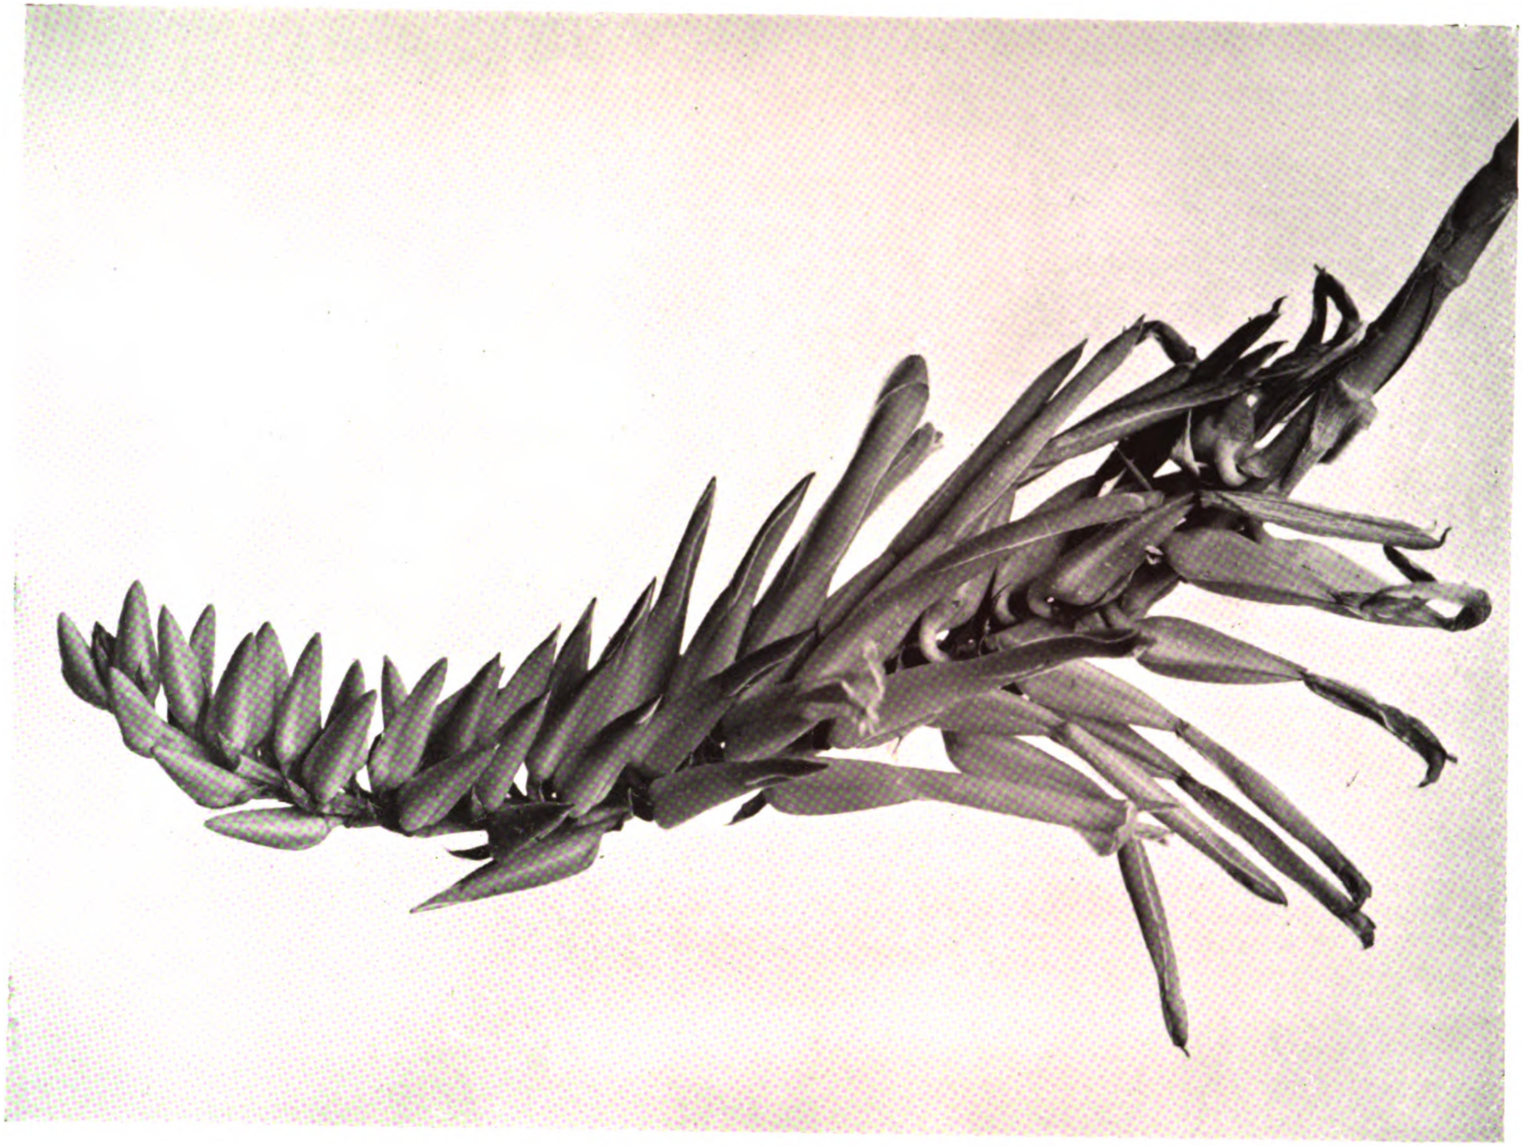
In his friendships, Collinson was singularly fortunate, for he managed to keep them all. Several members of the nobility, who were interested in planting their estates, received him with the warmest friendship; and for humble gardeners such as James Gordon, he would draw up little notes in his commonplace books full of praise for their skill in raising plants, stating that he does so as "an act of gratitude due to his memory from an old friend." His long employment of John Bartram as a collector of plants and seeds for himself and his friends was marked throughout by much kindness; and these two corresponded like brothers, although they had never met. In addition to paying for the collections made, he sent Bartram clothes, books, etc., and put him into communication with Sir Hans Sloane, Linnaeus, and others. His relations with Benjamin Franklin, dating from the time when he acted gratuitously as the London agent for the newly-founded Library of Philadelphia, showed his usual open-handed benevolence; and he was undoubtedly the means of turning Franklin's attention to his well-known researches into the nature of electricity.

Collinson did not publish very much. He contributed to the *Gentleman's Magazine*, and occasionally brought some investigation (sometimes not his own) to the notice of the Royal Society, of which he was a Fellow. He annotated his library, and was fond of collecting odds and ends of information in his commonplace books. He made a catalogue of his garden, but kept it in manuscript, though urged to publish it. Long after his death, it was found by L. W. Dillwyn, who rearranged it and published it as *Hortus Collinsonianus*, in 1843. Collinson's sympathies were extremely wide; and Major Brett-James points out in regard to his commonplace books, that they "show the breath of Collinson's interests, and the great number of people with whom he corresponded." His real contribution to horticulture consisted in the 171 new kinds of plants and trees he was able to introduce into English gardens; and a detailed list of these is given in the present work.

There are eighteen illustrations in this, the first full biography of Collinson, and it is somewhat to be regretted that they are for the most part but poorly produced. The portrait by Gainsborough, which serves as frontispiece, deserved to have been well reproduced, as it is here published for the first time; the original painting, offered for sale in 1907, cannot now be traced. Again, the small portrait of Linnaeus is unfortunately taken, not from one of the easily available good portraits, but from one which quite fails to bring before us his familiar features.

In spite of an occasional *lapsus calami*,

**The Life of Peter Collinson, F.R.S., F.S.A.* By Norman G. Brett-James. Published for the Author . . . and sold at The Friends' Bookshop, Endsleigh Gardens, London, price 15s. net.



PITCAIRNIA CORALLINA.

and the usual quota of printers' errors, this book is a very valuable addition to the biographies of the older horticulturists. It is full of good things, and a very thorough piece of work. Of the former, one cannot resist quoting Collinson's charming description of how a garden should be planted. "Everyone that would beautifully imitate nature should well consider the diversity and growth of trees, the size and shape of leaves, and the many shades of green. To know how properly to mix them in planting is another manner of painting with living pencils, for greens properly disposed throw in a mixture and contrast of lights and shades which wonderfully enliven the pictures, and which insensibly strike the senses with wonder and delight. The effects must be charming to see, the dark green Elm with the lighter shades of the Lime and Beech, or the yellowish green Planes with the silver-leafed Abele, the Chestnut, the Poplar, the Acacia, the Horse-Chestnut, *cum multis aliis*, when fanned by a gentle breeze, then how beautiful the contrast, how delightfully the lights and shades fall into diversity the sylvan scene."

The accompanying portrait (p. 46) from Nichol's *Literary Anecdotes*, although perhaps only a copy of Millet's engraving, is interesting on account of the sprig of Collinsonia at the base. *S. Savage.*

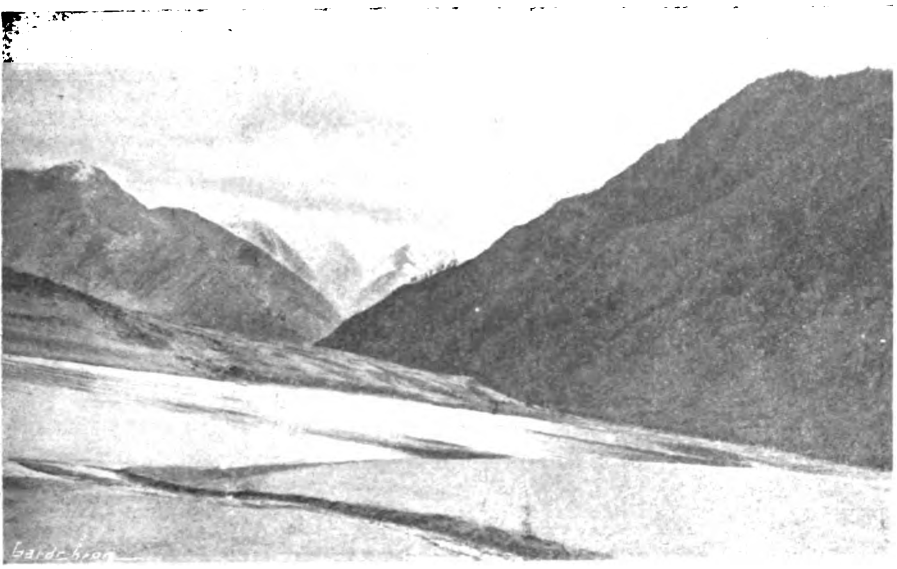


FIG. 23.—A WINTER VIEW OF THE TSANGPO, NEAR LHASA.

MR. F. KINGDON WARD'S EIGHTH EXPEDITION IN ASIA.*

XXIV.—Across the Tibetan Plateau.

On December 28, 1924, we finally started for India, following, at first, the road we had taken in August. But how different the conditions! Five months back it was raining continuously, and never did we see any of the high peaks. Now the sun shone brilliantly in a clear sky, and even from Tongkyuk we could clearly see the snow peaks of the trans-Tsangpo Himalaya.

A late start curtailed our march; and, indeed, what with the increasing cold as we approached the plateau, and early darkness, combined with a slight detour to explore a valley, it took us four days to cover ground which in August we had covered in two long marches. Meanwhile, I had collected seeds of that lovely Cyananthus to which reference has already been made—that was on December 30, certainly the latest date on which I have ever collected Cyananthus seeds. The form of the capsule, however, hinders the escape of the seeds, and so long as the whole plant is not snapped off and blown away, as happens in the case of C. incanus, growing on bare screes, there is no good reason why one should not collect it even later.

On December 31 we reached the Gompa, where we intended to halt for a day or two, in order to "fix" some snow peaks on the Salween divide. That very night the weather broke, and it began to snow fast, continuing all next day and the day after; meanwhile, the temperature, which had fallen to 14°F. on December 30, rose to 20°F.—or twelve degrees of frost, during the storm. Nevertheless, it is not to be supposed that we were either particularly warm or particularly cheerful, confined to a draughty, stone house, situated in that bleak alpine valley, up which the wind blew drearily.

Food now began to run short, so we decided that if the weather showed no sign of improvement we would cross the pass next day. On January 3, 1925, it was still snowing, so there was nothing for it but to abandon the project and march. Apart from the snow, we encountered no serious obstacle while crossing the pass, which is only about 14,000 feet high; and *en route* I collected seed of the ruby 'Sikkimensis' Primula. But when I attempted to reach the cliff where I had found 'Scarlet Runner' and 'Plum Warner' in bloom, I met with a rebuff. Not that there was any chance of getting seeds of these dwarf Rhododendrons, but I did hope to secure a few cuttings. The distance from the pass certainly did not exceed 300 yards; but the cliff faced north, and was very steep, indeed, precipitous, so that here the snow had drifted to impossible depths. After crossing the saddle, knee deep in snow, I quickly found myself floundering up to my waist, and an hour's struggle convinced me, not only that I should never reach the spot, but that I should never locate my plants, since every landmark was buried under one featureless quilt. So I reluctantly returned to the pass.

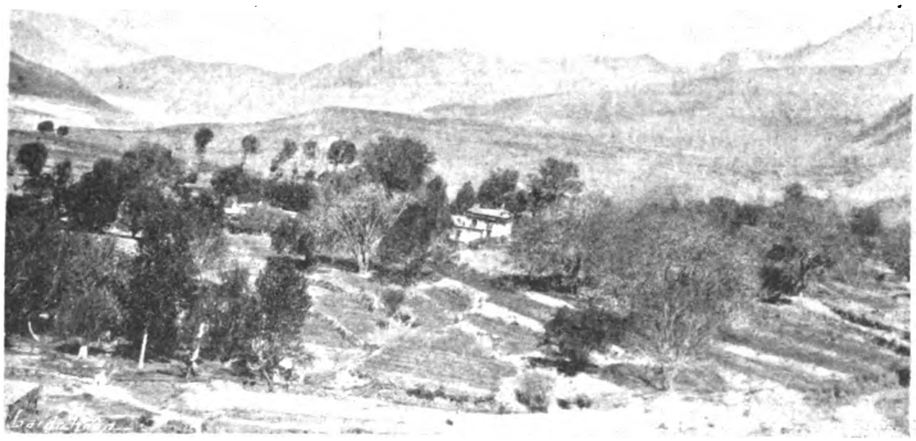

FIG. 24.—BIRTHPLACE OF THE PRESENT DALAI LAMA, WITH WALNUT AND OTHER TREES.

On January 5 we reached the Pasum Lake, and were at last out of the snow, though there was little improvement in the weather. It was our intention to cross the Salween divide as we had done in August; but after marching up the branch stream for three days to the last village, we learnt that the pass was closed. During this excursion I gathered seeds of the white and yellow 'Sikkimensis' Primula, which usually runs to two or three whorls of flowers, like a 'Candelabra'; it is probably only a form of the many-coloured one from Tumbatse. Selection should be able to do great things with this remarkable plant.

The weather now turned fine again, with clear nights, and we had further experience of really cold weather, the sheltered thermometer registering 39° of frost on more than one occasion. So we went down to the Gyamda river, and thence eastwards to the quite considerable town of that name, which we reached on January 18; and there, waiting for us was our mail, with the first news of the world beyond the mountains for three months. The weather was perfect, with an average of 20° of frost at night (under shelter) and no wind to speak of. There was no snow here.

The vegetation of the Gyamda valley is essentially scrub. Everything either pricks, like Ilex, Rosa, Berberis, Caragana, Sophora, Hippophaë, Elaeagnus, etc., or, if not actually beset with thorns, is twiggy and impenetrable. There are few herbaceous plants, and those reflect the prevailing dryness in their stout perennial root-stocks and long tap-roots—plant, like Salvia, Incarvillea, Senecio, Androsace, Gentiana, and the twining Codonopsis convolvulacea.

---

* The previous articles by Mr. Kingdon Ward were published in our issues of April 12, May 17, June 21, August 9, August 30, September 27, November 1, 1924, April 4, May 9, June 6, June 20, July 4, July 18, August 1, August 15, September 5, September 19, October 10, October 24, November 21, December 5, December 19, 1925, and January 2, 1926.

Above Gyamda, continuous forest ceases, but there are still patches of Conifer forest on the higher slopes. Poplar, Willow, Birch and Rhododendron, found on the sheltered flanks of the valley, are all small and stunted; while the open flank is covered almost entirely with scrub Oak. Continuing northwards or westwards, tree growth quickly dwindles, and once over the Salween divide, not so much as a bush—save a few gnarled Junipers—is seen. The only species of Rhododendron met with by the river are the 'Taliense' and the purple 'Lapponicum,' but there are others higher up including the 'Anthopogon.' Much bare rock is exposed, and to anyone coming up from the Tsangpo gorge, the region conveys a general impression of sterility; approaching Lhasa from beyond the Salween divide, on the other hand, Gyamda appears quite a fertile district.

We now marched northwards for two days, again approaching, but not crossing the divide.

North of Gyamda a good deal of snow still lay under the bushes on the sheltered slopes, and even the Junipers looked brown and morose. The scene grew more and more melancholy, the Rhododendrons with leaves rolled into tubes and hanging straight down, the leafless thickets of Hippophaë, and the growing areas of grey rock. Sub-alpine plants now put in an appearance—Iris, Primula, Androsace Henryi, Meconopsis horridula. Then came Potentilla fruticosa, Spiraea laevigata and Clematis; and finally an alpine flora, of which, however, nothing was visible at this season.

On January 22, we returned to Gyamda, and on the 24th took the Lhasa road westwards, up the main stream. After crossing the pass, over 16,000 feet, which leads down to the Lhasa river, we emerged on to the barren gravel plateau, and once more had to be content with yak dung for fuel; yet so cold was it that even that, with all its drawbacks, was better than nothing. True, it embitters the food, and draws tears from one's eyes, but we could not do without a fire, and certainly it does give out a generous heat.

The day we crossed this pass was a long one, for we did not reach the summit till 4 p.m., and we did not reach our destination till two hours after dark. The most frightful storms of wind were screaming up the valley, and both men and ponies were sometimes quite unable to make headway against them, and were forced to seek shelter from their violence. When we did at last reach a village, a wretched place it proved, though we could not distinguish much that night. Two hovels and two tents comprised the entire place. There was no cultivation—in these bleak uplands the people are herds and nothing else. We saw the yak and sheep wandering out up the stony slopes on the following morning, nibbling the crisp herbage where they could find any.

We were quite unfortunate here, for there was only one air-tight room in the whole village, and that had, of course, been reserved for us. But a rude chieftain, coming from Lhasa, and bound for the other end of Tibet, had arrived in the place an hour or two before us, and installed himself in our room, deaf to the protestations of the inn keeper that it was a reserved compartment. Nor would he vacate when we arrived and complained, and as he had an escort of six stout rascals, well-armed, we deemed it the better part of valour not to try and throw him out, though we were very annoyed. He apologised profusely next day, and begged us not to report his conduct to Lhasa, since that might have meant cashiering but meanwhile we had spent a wretched night in another draughty, earthen-floored cell, and were in no temper to promise anything. However, we did not report the matter, as the consequences might have been altogether disproportionate to the crime, and contented ourselves with telling him our opinion of his behaviour. I think that was the only occasion on which we were ever treated discourteously in Tibet.

We were now within a week's journey of the capital once more, and at this point we turned due south, in order to reach the Tsangpo. Travelling up a wide, grassy valley, we reached the top of the pass in a few hours, after a very gradual ascent. The saddle-like summit was really a small plain occupied by a lake, now, of course, frozen over, but thawing in the sunshine. Hundreds of yak, carrying *tsamba* to that benighted province of Kam (in exchange for salt), were halting here, where there was a certain amount of pasture; and we found a good trail stamped over the ice, which was quite awkward in places.

After crossing the pass, we halted for lunch, out of the wind, and found it really quite pleasant in the bright sunshine; I even fell asleep, after the disappointments of the previous night. But, later, the wind blew with great violence, and the azure sky became gloomy with clouds.

After crossing more frozen marsh where the valley was a mile or so wide, we began to descend into the usual steep, stony valley, and found here a considerable bush growth, including 'Anthopogon' and 'Lapponicum' Rhododendron. I noticed also big spikes of the Incarvillea in fruit—some of them were thirty inches high and bore about fifteen sessile capsules. But I never saw this plant—or any other Incarvillea—in flower, though if it is a good colour the clustered spires of bloom must be a fine sight. I. lutea, however, from Szechuan is a rather wretched thing, with washy and uncertain yellow flowers; and I. lutea has just the appearance of this high Tibetan plant. Let us hope the flower colour is healthier.

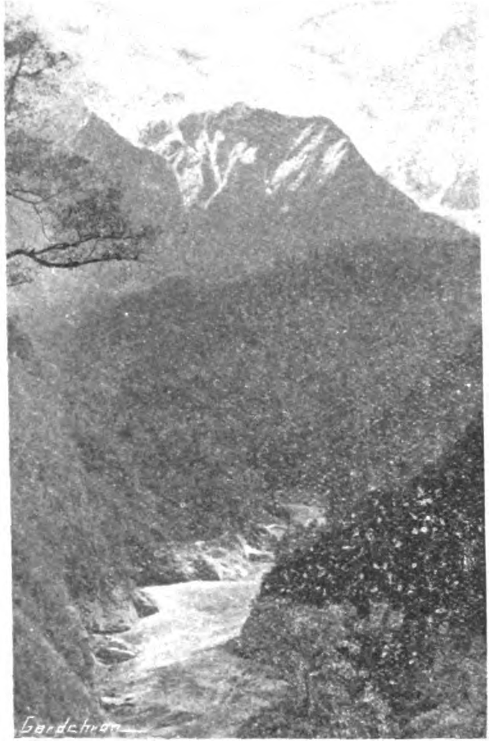

FIG. 25. IN THE TSANGPO GORGE.

We had hoped to get right down the valley to Oga Dzong, where we had been the previous April, this day; but night approaching when we were still some miles away, and the track being execrable, we halted at the first house we came to, situated a short distance from the road, up a side valley. Here, at any rate, we got some brushwood to burn again, and saw the big Cowslip 'Sikkimensis' Primula in fruit—it grows all the way down the Tsangpo valley, in favourable localities a thousand feet or so above the river, from this point (which is seventy miles east of Lhasa) to the entrance to the gorge; but nowhere does it flourish so well or grow so tall as in the *rong*, where we first met with it in flower. *F. Kingdon Ward.*

MESEMBRYANTHEMUM.

(Continued from page 30).

OOPHYTUM.

2. Oophytum, N. E. Br. Perennial, less than an inch high, tufted, succulent. Growths of small, ovoid (or under cultivation elongated-ovoid), soft and pulpy bodies, with a small fissure at the apex, having its lips closed or gaping. Flower solitary, partly or just exserted from the notch. Calyx produced above its union with the ovary into a short green (not membranous) tube, 6–7 lobed above. Corolla of numerous petals in 2–3 series, probably free, but in the withered flowers seen apparently united at the base into a very short tube, which may have been due to partial deliquescence and adhesion of the parts? Stamens many, erect. Style none; stigmas 6 or perhaps sometimes 5, filiform. Ovary half or more than half-superior, depressed and with 6 ridges on the top, 6-celled; placentas on the floor of the cells. Capsule with 6 valves and cells; each valve with its expanding-keels closely contiguous so as to form one stout, central keel distinct from the cell-partitions, and having broad, spreading membranous marginal wings, that are sometimes united in pairs between the valves; cells open, without cell-wings. Seeds several in each cell, small, compressed-ovoid, with a nipple at the narrow end.

Species 1, native of Van Rhynsdorp Division, South Africa.

The name is derived from the Greek, *oon*, an egg, and *phyton*, a plant, in allusion to the small egg-shaped growths of the plant as it grows under natural conditions.

I am unable to give a diagram of the floral structure of this genus, as the idea of making such diagrams did not occur to me on the only occasion I have had the opportunity of doing so.

O. oviforme, N. E. Br. Growths, as developed in South Africa, 4–6 lines high and 2–5 lines thick, becoming, under my cultivation, 6–9 lines high and 3–6 lines thick, ovoid, obovoid or cylindrical-ovoid, obtuse or very convex at the top, with an apical fissure-like orifice 1–2½ lines long: rather soft in substance; surface glabrous, thickly covered with minute pimples or raised dots as seen under a lens, green (not glaucous-green), with the dots or pimples darker and slightly shining; sheaths soft, pale brown. Flower just exserted from or the calyx included within the orifice. Calyx globose, 6–7-lobed, green: tube 1½–2 lines long, including the part adnate to the ovary; lobes 1–3 lines long and ¾–1 line broad, oblong, obtuse. Corolla 6–9 lines in diameter: petals numerous, in 2–3 series, 3–5 lines long, ⅙–½ line broad, linear, obtuse, stated to be rosy or pale magenta, but in the withered flowers seen are apparently whitish. Stamens numerous, 1–1¼ line long, erect. Stigmas 6, erect, about 1–1½ line long, filiform. Ovary half or more than half-superior, depressed and with six ridges on the top, 6-celled. Capsule 2–3 lines in diameter, somewhat depressed-subglobose, with 6 gaping double and somewhat wing-like ridges on the top, and with 6 valves and cells, when expanded about 5½–6 lines in diameter; valves reflexed when expanded, pallid, each with an orange-coloured central expanding-keel as long as the valve and pallid broad elliptic or subrectangular membranous marginal-wings; cells open, without or with only rudimentary cell-wings. Seeds 15–20 in a cell, ¼ line long, ovoid, with a nipple at the narrow end, smooth, light brown.—Mesembryanthemum oviforme, N. E. Br. in *Journ. Linn. Soc.* v. 45, p. 95 (July 1920). Conophytum oviforme, N. E. Br. in *The Gardeners' Chronicle*, 1921, v. LXX, p. 207, fig. 84, I-L, and v. LXXI, p. 231, fig. 123.

Van Rhynsdorp Division: In the Hardeveld, Marloth!; region of Van Rhynsdorp, Mrs. E. Rood!

An examination of more complete material than I had when I first described this plant demonstrates that the structure of the flower and fruit is quite different from that of Conophytum, as is also its mode of growth in the seedling and adult stages. In its seedling stage the cotyledonary body is smooth, but the first growth instead of merely replacing the cotyledonary body as in Conophytum is protruded much above it and is minutely papulose on the upper part and smooth at the basal part. It is translucent, especially at the smooth basal part, and contains air-cells inside, which glisten slightly when viewed with a lens. In the adult plant the growths develop out of one another so as to appear somewhat superposed until the old growth withers to a mere skin. This is a very different mode of growth from that of Conophytum, in which the successive growths merely replace each other, and so far as I have seen no species of Conophytum is at all papulose.

I have not seen a perfectly fresh flower, only two limp withered flowers that may have developed during their journey from South Africa, so that I am uncertain whether the petals are really free or whether in the process of withering they had clung together at the base so as to form a very short tube.

N.B.—The plant described as Mesembrythemum nanum by Schlachter, from the description and from the dried specimens I have seen of it, would appear to have somewhat the same general appearance as O. oviforme, but the single flower seen seems to be quite different, being very much smaller and on a slender exserted pedicel. However, the specimens are so badly pressed that it is quite impossible to determine the true structure and appearance of the plant, which I suspect belongs to some other genus. *N. E. Brown.*

(*To be continued*).

FORESTRY.

(*Continued from page* 32).

Owing to its great elevation above the horizon the sun's heat within the tropics is very much greater than it is at any other part of the earth's surface. As a consequence of this, wherever the conditions are sufficiently humid, we have in the tropical zone the most luxuriant vegetation on the face of the globe, although the tallest non-climbing, ligneous plants are not found there. For these we must go to more northerly and more southerly latitudes—to the forest regions of Western North America and of South Australia, where the tallest trees in the world are found.

The following table, from Dr. Julius Hann's *Handbook of Climatology,*[*] gives, in Bunsen-Roscoe units,[†] the relative chemical intensities of the light received directly from the sun and reflected from the sky upon a horizontal surface during a whole day at the spring equinox in the northern hemisphere:—

	Latitude.	From Sun.	From Sky.	Total
Pole	90°	0	20	20
Melville Island ...	75	12	106	118
Rejkjavik (Iceland) ...	64	60	150	210
Leningrad (Russia) ...	60	89	164	253
Manchester (England)	53	145	182	327
Heidelberg (Germany)	49	182	191	373
Naples (Italy)	41	266	206	472
Cairo (Egypt)	30	364	217	581
Bombay (India) ...	19	438	223	661
San Jose (Costa Rica)	10	475	226	701
Quito (Ecuador) ...	0	489	227	716

From this table it will be observed that there is a progressive diminution in the chemical intensity of the sunlight from the equator to the pole, but that in the tropical zone the rate at which it diminishes is comparatively slight, amounting to but ninety Bunsen-Roscoe units or thereby less at the tropic (23½° N.) than it is at the equator, or less than one-eighth of the total decrease for approximately one-fourth of the distance from the equator to the pole. It will also be observed that at approximately the 48th parallel of latitude the chemical intensities of the direct rays from the sun and of the light reflected from the sky are approximately equal, and, of course, to the north of this parallel the intensity of the light reflected from the sky is greater than that of the light received directly from the sun. This is the position as regards the intensity of the sun's rays at the spring equinox in the northern hemisphere, when day and night are equal over the whole of the earth's surface, and, instead of being tilted at an angle of approximately 23½°, were the earth's axis vertical to the plane of the ecliptic it would be the position throughout the whole year all over the globe. There would be no seasonal changes, no variation in the length of the day or night, no seasonal cessation of plant growth during any part of the year anywhere on the earth's surface. Under present conditions, however, as the earth moves in its orbit the position of its axis is constantly changing in relation to the sun, and of course the length of the day, and of the night, varies from latitude to latitude in the course of its journey. Within the tropics the variation is so slight as to be practically negligible, and plant growth, except through interruptions brought about by other than direct astronomical agencies, such as drought, etc., is continuous throughout the year. But as we go polewards from the northern and southern tropics (23½° N. and S.), which mark the limits of the sun's path north and south of the equator, after the spring equinox is passed the difference between the length of the day and that of the night becomes more and more accentuated until, when the arctic and antarctic circles respectively are reached, the distinctions between day and night disappear altogether for a short time at the summer solstice. At the poles the sun is a circumpolar star from equinox to equinox, and there is no night there for one half of the year, and of course for the other half of the year there is no day. These seasonal changes have, as is well known, a very marked influence on plant growth. Within the tropics it is practically continuous throughout the year, but at the extreme northern and southern limits of plant life the vegetative season is compressed into a period of but a few weeks duration. But at the middle of this short season of active growth at these extreme latitudes the daily duration of sunlight received by plants, although less intense, is immensely greater than it is anywhere, or any season, within the tropical zone for a corresponding period of time. *A. D. Richardson.*

(*To be continued.*)

ORIGIN, EARLY HISTORY AND DEVELOPMENT OF THE POTATO.

Most people, if asked the question, "Who introduced the Potato into Great Britain?" would probably reply, "Sir Walter Raleigh," and certainly they would be warranted in so doing by the sanction of long-standing tradition. Even a superficial study of the history of the Potato in this country, however, will reveal the fact that this opinion is based on very inconclusive evidence, and in this article an attempt will be made to sift the various theories regarding the origin of the Potato and its introduction into Europe, and to arrive, if possible, at a solution of the problem.

Origin.

There appear to be several schools of opinion concerning the locality in which the Potato originally grew in a wild state. A great many authorities claim Chili, and others Peru as its original home. Krichauff[*] states that the Potato has been found wild in Mexico. Wight,[†] who made exhaustive enquiry into the matter and a critical examination of material in American and European herbaria, and who, for the purpose of gaining first-hand information on the subject, made a trip through Chili, Peru, Bolivia and Ecuador, has expressed the opinion that there is no evidence of a single specimen of the Potato (Solanum tuberosum), having been collected in an undoubtedly wild state, or that the species is now growing anywhere in its original indigenous condition. It is thus practically impossible to fix the original habitat with any certainty; the probabilities are, however, that the Potato is native to the district embraced by the following countries:—Peru, Ecuador, Bolivia and North Chili. W. E. Safford, in a recent article[*], describes how along the arid desert which forms the Pacific coast of Peru and North Chili there is a succession of cemeteries in which mummies are found, accompanied not only by desiccated plants, but also by funeral vases of terra-cotta, some of which represent food stables and fruits of the ancient inhabitants. Dried Potatos were found by Safford in graves at Arica on the coast of North Chili. Funeral vases representing Potatos have been found in abundance in graves in northern Peru.

Some authorities, including Labergerie, Heckel, Planchon and Verne, claim to have found the ancestors of the cultivated Potato.[†] Since 1904 these gentlemen have worked with wild species of Solanum, and are of opinion that these species, especially Solanum Commersonii and Solanum Maglia, can give rise to the common Potato, Solanum tuberosum, by simple mutation. This theory, which may have had its origin in the use of impure material, is certainly not confirmed by the experience of a very large number of botanists and growers including Sutton, Berthault, Baker, Wittmack and Stuart.

Early History.

The first definite mention of the Potato in literature is that given in Cieca's *Cronica de Peru,*[†] published in Seville, 1553.[§] Cieca sailed with an expedition from Spain to Carthagena, where he landed in 1533. He began to record his experiences in a diary during 1541. From his diary it is evident that the Potato, or "Papas," as it was called by the natives, was grown to a considerable extent throughout those regions through which he travelled. It is clear also that the plant had been cultivated for some time prior to his visit. The country traversed by Cieca extends from the southern portion of what is known as Colombia to the region of Lake Titicaca. Reference is also made to "Papas" by Joseph D'Acosta, whose work was published in Seville in 1590, and by Garsilasso de la Vega, who was brought up in South America, and whose writings appeared in Lisbon during the year 1604.[‖]

There are many stories concerning the introduction of the Potato into the Old World, and owing to the lack of exact historical record, it is very difficult to separate the truth from fiction. Two separate modes of entry have been suggested, viz., (*a*) by the Spaniards, and (*b*) by the English. That there were two introductions may be inferred from the fact that the original English Potato had yellow tubers and light violet flowers, whereas the tubers of the European plant were red and the flowers violet. The Spanish conquest of Peru by Pizarro took place between 1531 and 1541. The first appearance of the Spaniards in Peru, however, dates back to 1526. The probabilities are strongly in favour of the introduction occurring towards the end of that period, or what is more likely, after it, and not at its beginning. The selection of the later date is based on the assumption that the plant could scarcely have escaped the notice of European botanists of that time for any considerable period. *T. P. McIntosh.*

MARKET FRUIT GARDEN.

THE first part of December was dry and very cold, but in the last fortnight rain fell on every day, bringing the total amount for the month up to 4.94 inches, which is considerably over the average. The rainfall for the year at my place amounted to 36.16 inches, which fell on 162 days, making 1925 the third of a series of very wet years, although it was slightly the driest of the three. March, June, August and September were the only months in which the precipitation was under the average. Fortunately, however, 1925 was a more profitable year than either of its two predecessors. Owing almost entirely to the heavy crop of Apples, there is a balance on the right side, though not a very brilliant one. Considering that Plums, Black Currants and Cob-nuts were very light crops, and that the market for Apples was in a depressed state almost throughout the year, the result is satisfactory.

A COSTLY DISEASE.

Now that the complete figures relating to my crop of Apples are available, I find that it was heavier than the crops of the two previous years put together. It fell a little short of the heavy yield of 1922; but I am surprised to find that, in spite of the fact that the quality of the fruit was decidedly inferior (1922 was a scab-free year with me), the total return was only about £200 less. As the general level of prices has certainly tended to fall since that year, the result can only be attributed to improved methods of packing and marketing. The utmost care was taken throughout the packing season in grading and making the most of the scabby samples of Apples. By selecting the clean fruits only for the best market, and finding a satisfactory outlet for the large proportion of rough fruits, returns were kept at a fairly satisfactory level. These remarks refer to dessert varieties only. Cooking varieties were of excellent quality; and I consider that mid-season sorts sold rather better than usual, owing, no doubt, to the shortage of Plums. Late sorts, on the contrary, were cheap.

In all the most valuable dessert varieties, with the single exception of Charles Ross, the proportion of fruit which had to be sold cheap because of scab was appalling. Had I been more successful in controlling this disease, I do not doubt that my profit on the year would have been increased by at least £400. What the loss must be, taking the country as a whole, can hardly be imagined. Yet no effort on an adequate scale is being made to discover more effective methods of control. Preventive spraying methods have been standardised for most of our overseas competitors, with the result that they are able to put clean fruit on our markets every year. I sprayed twice with Bordeaux mixture, and no doubt did some good, but nothing like enough; and the worst of it is that I am in very little better position for renewing the attempt this year. I can only experiment with earlier spraying.

I have been trying to trace some connection between the weather and the severity of scab. The only point which seems to stand out is the effect of a dry May in preventing the disease. In recent years the only seasons quite free from scab in my district were 1919 and 1922, and in both cases Apple blossom was expanded in May, when the weather was very dry. In May, 1919, only 0.25 inches of rain fell, and in May, 1922, only 0.56 inches, both months being sunny and warm. I had a good deal of scab in 1921, although it was a dry year throughout, every month having under the average rainfall; but May of that year, with 1.33 inches of rain, was not so dry as the same month in the two scab-free years mentioned. I cannot trace any definite connection between scab and the weather of the previous year. It is true that 1922 was preceded by a drought in 1921; but 1919 followed a year of over average rainfall, and the first four months of 1919 itself were all above the average for rain. Adequate protection during May is what we seem to want, and this is impossible to secure with our present spraying fluids when there is much rain to wash them off the trees.

BUSH FRUIT CULTURE.

I recently paid a visit to a grower who specialises in the culture of bush fruits, particularly large dessert Gooseberries. Incidentally, I found him grubbing some fine big trees of Lane's Prince Albert and other cooking varieties of Apples. He said he would rather grow Potatos which he could sell at 4/- a bushel, than Apples to dispose of at 6/- for the best grade. With regard to the bush fruits, which were seen in excellent order, the point which struck me most was that no digging, not even shallow forking, is tolerated in the actual rows of bushes. The weeds are scraped off with hoes into the alleys between the rows, there to be dug in deeply. Under Gooseberries and amongst Raspberries they are even pulled out by hand by women. As the digging proceeds some clean soil is thrown up to the bushes to replace that hoed away. Manure, particularly farmyard or town stable manure, is used very liberally. Great keenness is displayed in the finding of varieties which best suit the district, no doubt a most important point in the culture of bush fruits.

OVERCROWDED TREES.

I had contemplated doing a great deal of grubbing this winter to thin out trees which were planted too closely together some twenty years ago, and which are now decidedly overcrowded; but the cropping results of the past season have caused me to pause. The worst case is a block of Bramley's Seedling on the free stock, planted only twelve feet apart each way. These, of course, meet on all sides. Yet they have borne heavy crops for two years in succession; and last season the fruit was the finest I had of this variety, although there are blocks of Bramley's Seedling in all my plantations. So long as results are satisfactory it is generally best to leave well alone. The effect of thinning out often seems to be unfavourable to the surviving trees for a few years, probably because it cannot be done without a good deal of disturbance to their roots. I have found this to be the case even where old Black Currants have been cleared from amongst Apples, which appeared to need all the room. The trees have taken a year or two to recover from the disturbance.

I am all in favour of giving fruit trees plenty of space; but this is a matter which is apparently best provided for at planting time. We must intercrop with bush fruits in many cases, but these can be removed when their time is up with less disturbance than large trees.

Last year I grubbed alternate rows of a block of fine old trees of Beauty of Bath. The effect was most pleasing to the eye; but the trees carried a crop of the worst quality I have ever known them bear, although other blocks of this variety did well. There was nothing to account for it except the grubbing. The only alternative to grubbing is rather severe heading back. This I have never tried, as I imagine that it might defeat its own end by causing a lot of strong growth. It seems to be done in America, however, where it is called "de-horning." The method is to prune back to lateral branches, which thus take the place of the original leading branches. I intend to give the plan a trial.

UNRIPE WOOD.

Apple trees have much unripe wood. The tips of the leading shoots on young and medium-aged trees are decidedly green, and the leaves hung on them right into December, having turned an unnatural shade of brown. How they managed to stop on through all the frost and snow, and what else was wanted to make them fall, remain mysteries. I noticed these unripe shoots particularly when pruning trees of Blenheim Pippin planted seven years ago. The orthodox treatment, no doubt, would have been to cut off the unripened tips, and some gardeners would not think twice about retaining them. But I did not want to tip the leaders of this variety, and so delay still further its coming into bearing, always a slow business with Blenheim Pippin; therefore, I left the shoots their full length. What harm can result? I feel certain that these shoots will extend and behave next season just the same as if their tips had been properly ripened. In countries where fruit trees are subject to winter injury it would be a different matter. Another curious feature of this winter is that rabbits are doing no harm to fruit trees, in spite of the unusually severe weather. I have known them to do much damage in quite mild winters; so there is apparently no connection between rabbit trouble and the weather.

SUCCESS FOR SUMMER PRUNING.

Writing in the *Journal of the Ministry of Agriculture* for December, Mr. H. Goude, Horticultural Superintendent to the Norfolk County Council, whose work is always worthy of attention, records remarkable success in bringing young Apples into bearing by means of a method of summer pruning which he has adapted to some extent from the Lorette system. Illustrations from photographs show that the trees carried quite good crops in the third season after planting, although they were planted as maidens worked on the Crab stock. This has been done without any stunting, for the trees are well-furnished specimens with plenty of young shoots. Mr. Goude states that he has obtained similar results on the demonstration plots at Burlingham with most of the commercial varieties of Apples.

The method, briefly, is to pinch at the fourth or fifth leaf all shoots not required as leaders. The result of this pinching is to cause the bud in the axil of the top leaf to develop into a shoot, which is then rubbed out. In consequence two buds develop, one on each side of the scar thus formed. Many of these grow into weak shoots, which are rubbed out, but many develop into blossom buds the first season, and carry fruit the next year. The leaders are allowed to extend unchecked during the summer.

Winter pruning consists in merely shortening the leaders, if required, and making long spurs of any side shoots which have failed to develop blossom buds as a result of the summer pinching. It will be seen that this method differs from the usual system of summer pinching practised in gardens, in that the secondary growths are rubbed right out instead of being merely pinched back, and there is no further shortening of the laterals in winter except where they have failed to make blossom buds. Mr. Goude states that the system may be practised on older trees, every shoot being pinched at the fourth leaf, including the leaders, if no further extension is required. *Market Grower.*

FRUIT REGISTER.

APPLE TOM PUTT.

THIS Apple is a great favourite in the West of England, and is excellent for orchard planting. It is a good and constant bearer, thriving on the Crab stock, is an excellent culinary fruit, and is not to be despised for table use.

Well-coloured samples are exceedingly handsome; the flesh is soft with abundant juice, and the flavour is quite good. The variety is in season during October and November, and is undoubtedly a good orchard Apple; it is very useful as a cider fruit. *Ralph E. Arnold.*

APPLE PAROQUET.

THIS fine late dessert Apple was raised by Mr. Charles Ross, of Welford Park Gardens, from Peasgood's Nonesuch crossed with Cox's Orange Pippin, and distributed by Messrs. J. Cheal and Sons, of Crawley, in 1902, who described it in their catalogue of that year as "One of the most highly-coloured dessert Apples yet introduced; the fruit is of medium size, conical, eye closed in a shallow basin, stalk short, skin nearly covered with the deepest red, flesh white and of excellent flavour; good keeper, coming into use in December and January." The variety received an Award of Merit at the R.H.S. meeting in October, 1899. I purchased a standard tree in 1902 which has grown into a large specimen with a somewhat spreading habit, and is a constant bearer. The fruits are of a suitable size for dessert. This highly coloured Apple is too seldom seen on the exhibition table. *G. J. Warren, Balcombe, Sussex.*

[Accompanying Mr. Warren's letter were some excellent fruits of this showy and useful variety.—EDS.]

HOME CORRESPONDENCE.

Winter Thunderstorms.—I intend to continue, in conjunction with the Meteorological Office, the annual record of winter thunderstorms. I shall, therefore, be very glad to receive reports of thunderstorms observed by readers of *The Gardeners' Chronicle* in any part of the British Islands, between January 1 and March 31, 1926, inclusive. A note on a post card of the date and time of the observation of thunder or lightning, with the direction in which the lightning was seen, especially at night, will be very valuable. Any additional information of the following character will be extremely welcome:—(1) The time when the storm passed overhead or was nearest, with its direction, and how long it lasted; (2) an estimate of the severity of the storm; (3) whether it was accompanied by rain, hail or snow; (4) direction and strength of wind; change of wind, if any; (5) whether there was a change in temperature during the storm; (6) any other observation which may be of particular moment. It is particularly asked that the position of the place of observation should be indicated by mentioning the distance and direction from the nearest town. A note that no thunder or lightning has been observed during the period will be useful. *S. Morris Bower, Langley Terrace, Oakes, Huddersfield. December 21st,* 1925.

Perpetual-flowering Carnations.—I read with interest Mr. Grigor Roy's remarks on p. 501, vol. LXXVIII, in answer to Mr. Allwood's note on Perpetual-flowering Carnations. I have grown this type of Carnation for some years past and have never had any difficulty in raising good, healthy plants from very poor stock. This does not imply that one should make a practise of propagating from inferior stock, but only serves to show what can and has been done. I have seen very poor plants that have been sent from some of our leading Carnation growers, which again shows that we are very little better off when buying from them than we are by obtaining cuttings from our gardener friends. Much has been written from time to time on the coddling of Carnations, but I have very healthy plants that do well in a temperature of not less than 60 during very cold weather, although I know this is against all rules of Perpetual-Carnation growing. All my plants are free from disease. I often wonder why, under proper management, some gardeners' plants are troubled with red spider, as this pest is not difficult to keep down, at least, so I find. I always syringe the plants summer and winter, with salt water, which must certainly seem drastic to some growers of this plant. Although the temperature in which my plants are grown may seem high, it, of course, varies. I fail to see why Carnations should not do well in a high temperature and be free from disease if given a fair amount of air and light. On the contrary, I have seen very healthy plants that have passed through the winter with little or no fire-heat, but one can hardly call them Perpetual-flowering, as in this low-temperature they just about reach bud stage, but seldom open their blooms until warmer days. Indeed, very few plants flower without fire-heat during the winter. I have written this to show that, by quite diverse ways, one may obtain, and keep, healthy stock. *H. Howard Grace, Newton Park Gardens, Bristol.*

Problems of Fruiting.—I agree with Mr. Weston (p. 392, vol. LXXVIII,) that we are able to do very little to influence the cropping of fruit trees in the open once they have grown to full bearing age. This is proved by the fact that crops vary little over a wide district in any particular year. In the early summer of the last two years I have visited a number of fruit farms in certain districts and have found prospects about the same in all, although the grower's methods vary considerably. This extends even to certain varieties. We get Lane's Prince Albert years, for instance, when there are heavy crops of this variety in practically every orchard over a wide district, or even throughout the country. In seasons when frost or other unfavourable weather conditions do damage at blooming time, there is more variation in the crops, because the situation of the orchard then has its influence; but it is very seldom that one can trace the influence of any treatment on the cropping. Claims that this has been done have often been made, but without satisfactory proof. If control trees were left when any special treatment was given it would generally be found that results were negative. In the case of Cherries it is always the weather at blooming time that influences the crop, as they bloom every year; but Apples have a marked alternate-year bearing habit; and no one has so far been able to prove sarisfactorily that he has overcome this. The only way to get a crop every year seems to be to have trees of various ages, so that their "off" years are not the same in all cases. I do not mean to imply that good culture does not pay. It is an easy matter, for instance, to lose the crops of two seasons by neglecting to control a severe attack of some insect pest. But, provided the trees have ordinary good treatment, and that they are not starved, we find, much to our annoyance, that our crop prospects are much the same as those of our neighbours every year. *Market Grower.*

Aralia cordata.—This plant, called Udo by the Japanese, grows wild in hilly regions of Japan. It is extensively cultivated in improved forms both winter and spring, as a market crop. Outside Japan it is little known although it has been introduced by Dr. D. G. Fairchild, of the United States Ministry of Agriculture, into that country. It is hardy in most parts of England, and may be grown and blanched like Rhubarb. Forced like Seakale and Chicory, the young shoots provide a delectable vegetable which, served *à la crème*, is so tender that it may be cut by a paper-knife, whilst its ivory-white colour and delicate flavour afford an escape from the ubiquitus Brussels Sprout. *W. Lawrence, Burford Lodge, Dorking.*

The late Mr. S. B. Dicks.—Many readers of *The Gardeners Chronicle* will, like myself, miss with much regret the interesting and knowledgeable articles on vegetables so ably written by the late Mr. Dicks. It is obvious that this gentleman had taken every opportunity of his travels and concentrated his powers of observation in obtaining knowledge of vegetables in many countries where their uses are much more widely known than in our own. In his last article on Scorzonera, a vegetable little grown in this country, his suggestion that the cause of this vegetable being overshadowed by its congener, Salsify, is not necessarily due to the superior merit of the latter, is very much to the point, and shows an intimate knowledge of both vegetables. That the successful cultivation of Salsify offers less difficulties than that of Scorzonera is probably true, and will account for the former being more widely grown. Well-grown roots of the latter are, however, at all times equal to the best Salsify, and, as Mr. Dicks pointed out, much superior when they are required for late use in the season. I have always been very keen to make the acquaintance of plants which furnish suitable material for the mixed salad bowl, but previous to Mr. Dicks's information I did not realise that the leaves of Scorzonera could be included. *W. Auton.*

SOCIETIES.

ROYAL SCOTTISH ARBORICULTURAL.

ABERDEEN BRANCH.

THE annual meeting of this branch was held recently. Mr. Charles S. France, the retiring president, occupied the chair.

The annual report and accounts were submitted by the secretary and treasurer, Mr. George D. Massie, advocate, Aberdeen. The report, the twentieth of the branch, gave the membership as 173. The financial statement showed a total balance to the credit of the funds of £33 19s. 11d. Both reports were regarded as satisfactory and unanimously adopted.

The chairman intimated his intention not to continue in office as president for the usual period of three years. He nominated as his successor Mr. John Michie, M.V.O., Kincairn, near Aberdeen, one of the original members of the branch, and a vice-president since it was initiated. Mr. Michie occupied the high and honourable position of forester and factor on the Royal estates at Balmoral under Queen Victoria, King Edward VII and King George.

Mr. Michie, accepting office, said he had been associated with the parent society since 1881, and had participated in the management of its affairs, more of less, ever since. He had taken a part in such work during a time when forestry was only taken up by very few indeed.

Other appointments of office bearers were made as follow:—Vice-presidents: Lord Forbes, Castle Forbes; Captain R. J. Nicoll, of Ballogie, Aboyne; Mr. Donald Munro, O.B.E., Banchory; and Mr. S. J. Gammell, of Counteswells. In place of Lord Forbes, Mr. C. S. France was added to the committee. To that body Mr. James S. Davidson, Cairnlea, Aberdeenshire, and Mr. J. F. Annand, of the Forestry Commission (Aberdeen District) were re-elected. In place of Sir J. D. Ramsay, Bt., H.M. Commissioner at Balmoral, Mr. Edwards, forester, Balmoral, was chosen, and Dr. Watt, Forestry Department, Aberdeen University, was elected in the place of Mr. Peter Leslie, M.A., B.Sc., Aberdeen University. Mr. Edwin C. Duthie, of Messrs. Ben Reid and Co., Aberdeen, and Mr. S. J. Gammell were appointed representatives to the parent society in Edinburgh. Mr. George D. Massie was re-appointed secretary and treasurer.

Intimation was made of the gifting to the branch library of a number of interesting pamphlets and books on forestry by Mr. S. J. Gammell, and also reports and bulletins from Mr. C. E. Leggat, of the Forest Department of the Union of South Africa, Pretoria.

After the general business was concluded, the members were entertained by a very instructive address on "Peat Planting," by Mr. Ernest V. Laing, M.A., B.Sc. (Forestry), of the Forestry Department, Aberdeen University. Peat, in Scotland, said Mr. Laing, was mainly of the high moor type, characterised by high water content and low air content, poor nutritive value,—although the ash analysis usually showed sufficient food material for tree growth, and high degree of acidity. To bring the peat into anything like fertility the excess of water had to be removed. Were this done successfully, the other hostile factor would automatically disappear. Drainage, unfortunately, in regions of high rainfall, such as the west of Scotland, was often ineffective, but drainage effected might be intensified by turf planting. The operation might be successful in itself, but greater success might be achieved by the application of manure to the turf. Invariably the manure used had been basic slag, owing to the success met with by its use on the Continent, and because it supplied lime and phosphate, of which high moor peat was markedly deficient. Soil in all cases increased the value of the fertiliser. It was suggested that other manures might give greater success. The first practical point was the minimum amount of manure which would give the necessary stimulus to growth. This amount would vary with different peats—it might vary from one to four ounces or more of slag per tree The second point was that, to permit of complete aeration, the drained part must be left unplanted for at least one year.

In all instances success to a great extent would depend on the species of tree used, the protection afforded to the tree, the thorough cleaning of the land from weeds, such as Bracken or grasses, and the careful treatment and planting of the tree in order to make it as vigorous as possible. The three principal trees used in planting peat were Scots Pine, Norway Spruce and Sitka Spruce. .Scots Pine was the most suitable tree for eastern peat lands. The Spruces, particularly Sitka Spruce, were more adapted for peat regions of high rainfall, such as he west of Scotland..

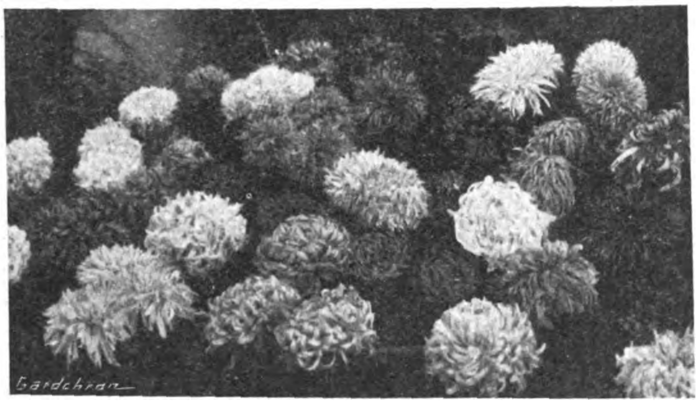

FIG. 26.—CHRYSANTHEMUMS AT MYSORE SHOW.

MYSORE HORTICULTURAL.

I **SEND** a somewhat belated account of our summer show which was held on August 8. 1925. The exhibition was fully up to the usual high standard and proved a great success. The exhibits of foliage plants, perennials and annuals in pots showed good cultivation, and the various prizes were keenly competed for. Roses (Fig. 27) were not so good as those exhibited at the previous shows, but Dahlias and Chrysanthemums (Fig. 26) stood out distinctly with their splendid blooms in many new varieties. Fruits (Fig. 28) and vegetables were of good quality, though not present in such large quantities as usual. In the cut flower section there was keen competition among the general collections and in floral arrangements. There were numerous and effective exhibits of table decorations, vases, baskets and bouquets. An innovation of great public interest consisted of a special section of horticultural scientific work developed in the Government Botanic Garden in recent years. The exhibits were arranged in a separate tent under different sections. Under "Plant Diseases," coloured drawings of plant lice, scale insects, Orange borers, Grape vine mildew, and the full life history of the woolly aphis—which has done so much damage in the Apple orchards—were shown. The use of various sprays and insecticides, as well as chemicals used in combating the diseases, were demonstrated.

Among the newly-introduced horticultural implements were shown seed-testing apparatus, seed-sowers, soil-testers, seed-samplers, and various tools such as cultivators, secateurs, etc.

In another section, the following seeds and plants of economic importance were exhibited :—Green Manures : Clovers, Velvet Beans, Crotolarias, etc., and Fodders : Bokhara Clover, Lucerne, Sunflower, Salt Bush, Napier Grass and Rhodes Grass. An entirely new strain of Befri evolved on the Sunkal Horticultural Farm was also shown. This is said to have double the nutritive value of Wheat..

Of industrial plants yielding fibres, rubbers, oils, drugs, etc., very large numbers were shown, together with samples of the products derived from them. I can only mention a few, such as Sisal Hemp, Silk Cotton, Camphor, Styrax, Balsam, Annatto, Carob-Bean, etc. In this connection a very interesting exhibit of scents prepared by Mr. PRIORIS was shown. The plants used are grown on over 200 acres of plantation, and consist of Pelargoniums, Jasmines, Tuberoses, Roses and Oranges, showing that this industry can be profitably developed in India.

The poultry section, which the Horticultural Society added to the show last February, created great interest, and the exhibits were not only numerous, but showed excellent quality both in "Exhibition" as well as "Utility" points.

In the point of number of visitors, the show was well-patronised, and the visitors greatly appreciated the music of the Palace Orchestra, kindly sent by His Highness the Maharaja of Mysore, this feature being in keeping with flower shows at home.

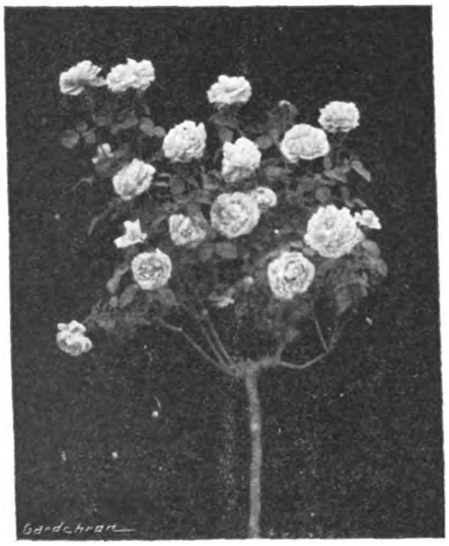

FIG. 27.—PAUL NEYRON ROSE AT MYSORE SHOW.

At 5.30 p.m., the prizes, so far as they consisted of Cups, Medals and silver articles—and which included those for the garden competition—were given away by Mrs. Pears, who was accompanied by the Hon. Mr. S. E. Pears, British Resident in Mysore. Lady Banerji won His Highness the Maharaja's Large Silver Challenge Cup for the largest number of prizes taken at the show.

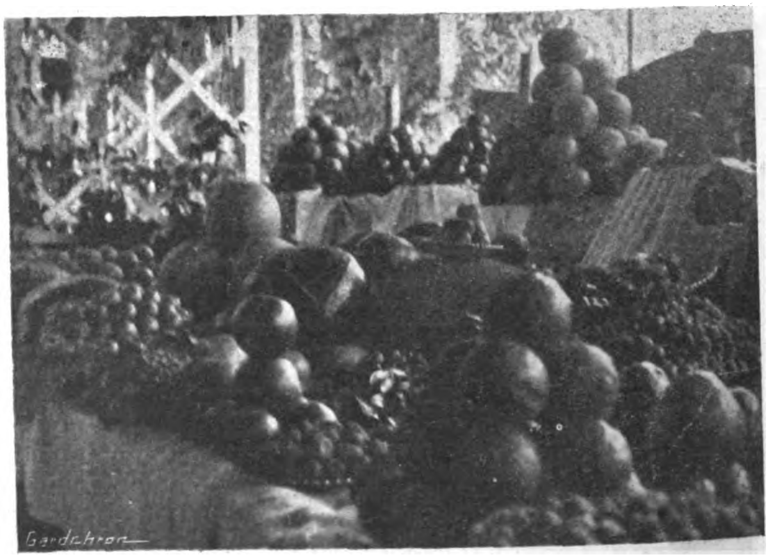

FIG. 28.—COLLECTION OF FRUITS AT MYSORE SHOW.

The Horticultural Society is to be congratulated on the splendid success achieved, and on the great expansion of its activity. *H. C. J.*

ROYAL HORTICULTURAL.

AT the first meeting of the New Year, held at Vincent Square on Tuesday, January 12, there was a bright and interesting exhibition and a fair attendance of Fellows. Orchids were unusually prominent and provided most of the colour and interest; it is worthy of note that the two largest displays were from amateur growers, one coming from Glasgow and the other from Gloucestershire, and for each of these the Orchid Committee recommended the award of a Gold Medal

Orchid Committee.

Present: Mr. C. J. Lucas (in the Chair), Mr Gurney Wilson (Hon. Sec.), Mr. Fred J. Hanbury, Sir George Holford, Mr. H. J.. Pitt, Mr. S. W. Flory, Mr. Arthur Dye, Mr. Fred K. Sander, Mr. H. G. Alexander, Mr. Charles H. Curtis, Mr. A. McBean, Mr. J. C. Cowan, Mr. H. H. Smith, Mr. T. Armstrong, Mr. Robert Paterson, Mr. J. E. Shill, and Mr. Stuart Low.

FIRST-CLASS CERTIFICATES.

Brasso-Cattleya Mrs. Robert Paterson (*C. Clotho* × *B.-C. Cliftonii magnifica*).—A fine hybrid of excellent form and size and beautiful colour. The broad petals and the somewhat smaller sepals are a lovely shade of soft rosy mauve. The lip is frilled but not fringed, and is rosy mauve at the base with a broad crimson-purple front portion and a yellow throat. Shown by Messrs. BLACK AND FLORY.

Cypripedium Marmion ,Holford's var. (*Germain Opoix* × *Jura*).—In this hybrid the high colouring suggests great possibilities. The segments are all broad and of great substance. The rounded dorsal sepal has a wide white margin but the rest of the sepal is rich deep port-wine colour; the petals have a green margin surrounding a broad area of reddish-brown, almost a dark crimson. The lip is green, shaded with brown. Shown by Sir GEORGE HOLFORD (gr. Mr. H. Alexander), Westonbirt.

Cypripedium Christmas Cheer (*parentage unknown*)—A handsome Cypripedium suggesting a close affinity with C. Cappa Magna. The broad, dorsal sepal has a white apical margin which sets off the deep red of the centre that shades to deep rose as it nears the white margin. The wavy petals are rich reddish-brown edged with green, and the lip is of similar colour. Shown by ROBERT PATERSON, Esq., Cathcart, Glasgow.

AWARDS OF MERIT.

Cypripedium Saladin (*Chapmanii* × *Olenus.*)—An interesting hybrid with very broad sepals that have a whitish, green tinged ground, almost covered with reddish-purple spots. The lip is elongated and dull rose colour, while the dorsal sepal is white, faintly shaded with green and veined with deep rose. Shown by ROBERT PATERSON, Esq.

Cypripedium Baldur (*G. F. Moore* × *Niobe*).—An attractive flower of medium size and good form. The rounded dorsal sepal has a green base, but the major portion has deep reddish-rose shading and lines on a white ground. The petals are brown and green and the lip of similar colouring. Shown by Sir George Holford.

Cypripedium St. Kentigern (*Albert Fisher* × *Perseus*).—Although this hybrid has rather weak petals of a rich brown and green colour, it is the vivid wine-red colour that occupies most of the dorsal sepal, which is the great attraction. Around this brilliant area runs a white margin, into which the richer hue extends in spots and irregular markings. Shown by Robert Paterson, Esq.

Miltonia Princess Mary var. roseum (*Hyeana* × *Bleuana*).—A pretty Miltonia of pleasing rose-pink colour, the shade being deeper on the sepals and petals than on the broad, bilobed lip. The radiating disc is deep rose-red. Shown by Robert Paterson, Esq.

Cymbidium Erin, Gatton Park var. (*gattonense* × *grandiflora*).—The latter parent has left its mark on its progeny as the big, substantial flowers have solid apple-green sepals and petals, each with a few brown dots at the base. The side lobes of the lip are green on the outside, and the apex is creamy white, but on all these divisions of the labellum there are rich chestnut-brown spots. Shown by Sir Jeremiah Colman, Gatton Park, Reigate.

Groups.

One of the largest of the several fine displays was from Robert Paterson, Esq. (gr. Mr. A. Merry), Stamperland House, Cathcart, Glasgow. The plants had come a long journey, but had not suffered in transit. The group was well arranged, and consisted largely of Cypripediums, for which the Stamperland collection is becoming famous. The central feature was a grouping of Odontoglossums, Odontiodas, and Cymbidiums, the yellow and brown Odontoglossum triumphans showing up well at the back. Fine spikes of Odontioda Colinge and Odontoglossum Miguelito were noted, as well as a good example of Miltonia William Pitt. A few outstanding Cypripediums were C. Britain's Monarch, C. Saladin, C. Major Hanbury Carlisle, with huge green and white flowers; C. Maisie, the white C. Boltonii, C. Arthurianum var. Sanderianum, the dark-hued C. St. Kentigern, C. Monialis var. elegans, and the graceful C. Ballet Girl—altogether a grand exhibit.

The outstanding exhibit on this occasion was the grand display of finely-grown Cypripediums made by G. F. Moore, Esq. (gr. Mr. Page), Chardwar, Bourton-on-the-Water. The group consisted of about two-hundred plants, and these were charmingly arranged on a space of about thirty-six feet by six feet. A large proportion of these Cypripediums were raised at Chardwar, but there were others, such as C. Boltonii, C. Golden Fleece, C. Argo-Fairrieanum, and C. Maudiae, the last being very finely represented. Coming to the big, bold varieties, we can name a few only, those which attracted us by reason of form or colour:—C. Memoria F. M. Ogilvie var. Rex, C. Christopher var. Blanche, C. Christopher var. Grace Darling (very fine), C. Mrs. Eley var. Commodore, C. Peggy (Thomsonii × Fairrieanum), G. Gwen Hannen, C. Memoria H. J. Elwes var. Nerine, C. The Great Mogul, C. Doris Stanton, C. Chrysostom var. Richard Fort (wonderful in form and its yellow, green and white colouring), C. The Prince (a free-flowering hybrid between Tommy Curte and Goliath), the gigantic C. Gwen Hannen var. Field-Marshal, and the almost equally large C. Chrysostom var. Lord Lambourne. All the plants were grandly grown and it appeared to us that the flower stems were taller than we have seen them in previous displays from Chardwar.

Mr. H. T. Pitt's exhibit (gr. Mr. Thurgood) included several very interesting Orchids, notably three spikes of Eulophiella Rolfiae (awarded a Cultural Commendation), with numerous large, deep rose-coloured flowers; Epidendrum Endresio-Wallisii, largely represented, Angraecum rhodostichum, Trichopilia Goldei, Miltonia Endresii, Maxillaria luteo-alba, Odontoglossum Uro-Skinneri alba and other subjects that are so well grown at Rosslyn.

Coelogyne Mooreana with four fine spikes of its white flowers was shown by Sir Jeremiah Colman (gr. Mr. J. Collier), Gatton Park, Reigate, who also contributed several excellent Cymbidiums, C. Erin, Gatton Park var., attracting a good deal of attention by reason of its deep apple-green sepals and petals and the bright red-brown spots on the lips.

A pleasing display was made by Messrs. Stuart Low and Co., whose graceful exhibit included arching spikes of Odontoglossum Helvetia, O. Cardinal Wolsey, O. crispum, Odontioda Wilsonii and O. Bohnhoffæ, and Cybidium Atalanta. In addition to these there were examples of Oncidium bi-callosum, the handsome Sophro-Cattleya Doris, Cypripedium Tautzianum, the showy Brasso-Cattleya Ruby and the old Cypripedium Schlimii.

Messrs. Cowan and Co. presented a most attractive exhibit in which Oncidium splendidum was well represented, together with several Cymbidiums, Miltonia Bleuana var. Reine Elizabeth, and a fine lot of Cypripediums. These last included C. Golden Wren, C. Cyril Lee, the big C. Leeanum, Blenheim var., C. Elsie II, a showy hybrid between C. Hermes and C. Lady Dillon; C. Albert Fisher and the elegant C. Minos var. Youngii.

Messrs. Sanders contributed a collection of Cypripediums, Cymbidiums, and other Orchids, including the dainty little Oncidium ornithorhynchum and the quaint Cirrhopetalum Thouarsii. Very fine were their specimens of Cattleya Titus and C. H. S. Leon, while Laelio-Cattleya Fatima, in dull gold and bright purple, was very attractive. Cymbidium Moira var. Dulce, with three large spikes, was the central plant of this group.

Messrs. James Cypher and Son brought up a nice lot of Cypripediums, and of these we were attracted by C. Trollius var. Craveniamum, C. Mirum, C. Alabaster, C. Cupid, C. Alcibiades, and C. San-actaeus. Masdevallia tovarensis, Odontoglossum aspersum, and Brasso-Cattleya Winslow were included in this exhibit.

Messrs. J. and A. McBean had a comparatively small group, but they showed capital spikes of Cymbidium albanense, C. Schlegelii, Odontoglossum Pyramus, O. triumphrosum, some good forms of O. crispum, Odontioda Dovere (very handsome deep, Venetian red), and the finely-formed Laelio-Cattleya Sunbelle.

Messrs. Charlesworth and Co. showed some specimens of their fine strain of Odontoglossum xeximium zanthotes, the attractive Odontonia Dora, several huge blooms of Brasso-Cattleya British Queen, Odontoglossum Nada (very brightly coloured), and an enormous flower of Cypripedium Major Hanbury Carlisle.

In Messrs. Black and Flory's exhibit there were numerous fine Cypripediums and bright examples of Cattleyas and Lælio-Cattleyas. Cypripedium Yule, and C. Antasia were two fine Lady's Slippers. Choice Odontoglossums were a feature of Messrs. Armstrong and Brown's exhibit, and one of these, O. Harvengtense, Rosefield var., brought back many memories. Odontiodas were also good and there were excellent inflorescences of Laelio-Cattleya Schroderae, in addition to a selection of Cypripediums.

Mr. Harry Dixon showed a few Odontoglossums and Cypripediums, Oncidium cheirophorum and Sophronitis grandiflora. Messrs. A. J. Keeling and Sons sent a few Cypripediums and the yellow-edged Odontioda Marigold (Bradshawiae × Odm. triumphans).

Floral Committee.

Present: Section A.—Mr. H. B. May (in the chair), Mr. A. Turner, Mr. E. M. Wrightman, Mr. H. J. Jones, Mr. J. M. Bridgeford, Mr. Wm. Howe, Mr. D. Ingamells, Mr. M. C. Allwood, Mr. F. G. Cousins, Mr. E. R. Janes, Mr. W. H. Page, Mr. Jas. B. Riding, Mr. H. L. Smith, Mr. A. Vasey, Mr. W. B. Gingell, Mr. D. B. Crane, Mr. W. P. Thomson, Mr. F. Streeter, Mr. Chas. E. Pearson and Mr. G. W. Leak.

Section B.—Mr. Charles T. Musgrave (in the chair), Mr. James Hudson, Mr. G. Reuthe, Mr. G. C. Stern, Mr. W. J. Bean, Mr. E. A. Bowles, Mr. T. Hay, Mr. G. Yeld, Mr. A. Bedford, Mr. F. G. Preston, Mr. L. R. Russell, Mr. Amos Perry, Mr. R. D. Trotter, Mr. R. C. Notcutt and Sir William Lawrence, Bart.

Awards of Merit.

Chrysanthemum Winton—This is a valuable decorative variety of Japanese type and useful market size. It is a graceful bloom made up of broad, pointed florets of rich yellow colour. Shown by Messrs. Tacon and Horwood.

Dombeya Glaneliae (provisional name).—A well-grown plant of Dombeya was provisionally named Dombeya Glaneliae. It was a robust, erect, single-stemmed shrub. The leaves, which measured a foot across, are ovate-reniform in shape, slightly triangular at the tips, of soft texture, lightly toothed, and the prominent ribs are often touched with reddish colour. The flowers are borne in a dense pendulous corymb, with leafy bracts, and are of a bright pink colour with small carmine blotches at the base of the petals. The leaves and flower stems are covered with a fine tomentum. We understand that Lord Glanely brought a plant from Madeira, though the genus is mostly tropical African, spreading south to Natal. There are known to be fully one hundred species, but few are in cultivation. Shown by Lord Glanely (gr. Mr. Bannerman), Chippenham.

Groups.

In a large floor space near the gallery stairs the Hon. Vicary Gibbs (gr. Mr. E. Beckett), Aldenham House, Elstree, arranged a large group of well-grown plants of Euphorbia (Poinsettia) pulcherrima and its varieties roseaf carminea and alba, under drooping leave so three luxuriant specimens of Kentia Fosteriana.

Messrs. Cragg, Harrison and Cragg showed particularly good flowers of their new Chrysanthemums Bianca and Phryne, and the Hon. Vicary Gibbs staged equally good blooms of the white-flowered Madame Oberthur.

Carnations were exceedingly well shown by Mr. C. Engelmann, who had splendid blooms of Laddie, Red Laddie, Rouge, Nero, and other good varieties. At one end of the Carnations Mr. Engelmann had an enviable vase of Roses. The varieties were America, Premier, and Columbia.

Amongst the good Carnations shown by Messrs. Stuart Low and Co. were vases of Philip Sassoon, Mauve Queen, and Topsy, and they also staged a few profusely-flowered plants of Cyclamen persicum varieties. Messrs. Allwood Bros. included vases of Shot Silk, Master Michael Stoop, George Allwood, and Edward Allwood in their collection of Carnations, and also showed some vases of Dianthus Allwoodii.

There were several interesting little rock gardens. Messrs. Wm. Cutbush and Son made their sandstone rockery bright with heavily-berried little bushes of Pernettya mucronata and its varieties, graceful sprays of Hamamelis arborea, Galanthus Elwesianus robustus, and other subjects.

Iris unguicalaris, I. reticulata and I. sind-pers were freely planted by Messrs. Waterer, Sons and Crisp in their small rock garden which also contained plants of the elegant little Sisyrinchium grandiflorum and Anemone fulgens.

In addition to his miniature alpine gardens Mr. F. G. Wood built one of conventional design and furnished it with the pretty Crocus Sieberi, Christmas Roses, Polyanthuses and Snowdrops. Messrs. L. R. Russell, Ltd., had a number of bushes of Hamamelis arborea and Berberis aquifolium, and the Misses Hopkins set up a neat little rockery.

A large number of flowers of their excellent strain of St. Brigid Anemones were shown by Messrs. R. Gill and Son. Mr. Klinkert again exhibited well trained topiary examples.

An extensive selection of well made garden tools, artificial manures, peat, loam, and other garden necessaries was attractively displayed by Messrs. Wm. Wood and Son. In what has almost become their usual corner Messrs. Thos. Gunn, Ltd., again showed a good collection of garden tools. Messrs. Sander and Co. contributed many vases and other garden ornaments.

There was a considerable number of exhibits of paintings and drawings of garden scenes and flowers.

Fruit and Vegetable Committee.

Present: Mr. C. G. A. Nix (Chairman), Mr. W. Poupart, Mr. H. S. Rivers, Mr. George F. Tinley, Mr. J. Cheal, Mr. P. C. M. Veitch, Mr. P. D. Tuckett, Mr. W. Giles, Mr. A. Bullock. Mr. T. Pateman, Mr. A. Metcalfe, Mr. E. Beckett, Mr. A. Jordan, Mr. J. Wilson, Mr. E. Neal, Mr. W. H. Divers, and Mr. A. N. Rawes.

Apple Saltcote Pippin, which Mr. H. Chapman, Rye, submitted for award at the Holland Park exhibition on September 22, 1925, when the Committee requested to see fruits later, was again shown, but the fruits were somewhat shrivelled and, judging by the flavour and texture, much past their best. The variety, however, is of very attractive appearance, and, when eaten at its best, is undoubtedly of much merit. The Chairman stated that he had a tree which had made exceptionally strong growth. In view of its possibilities it was recommended to be grown at Wisley in the trial of commercial fruits.

A small but very good Apple of the Cockle Pippin type known as High View Pippin, was shown by Mr. E. Hill, High View, Weybridge (gr. Mr. F. Fitzwater). Unfortunately the fruits are too small to warrant an award, but they are very attractive in appearance, of conical shape and excellent quality. The variety is said to have been raised from Sturmer Pippin crossed with Cox's Orange Pippin.

Messrs. Sutton and Sons exhibited 128 distinct kinds and varieties of vegetables, having in all 130 dishes. This splendid collection included practically everything the kitchen garden affords at this season and many forced out of season, such as Seakale, Chicory, Endive, Mushrooms and Dandelion. These blanched vegetables were all exceptionally fine. A prominent position was given to some splendid bulbs of Ailsa Craig Onions, and at the back of these were some remarkably fine Leeks of the variety Acquisition. Other good Onions shown were Improved Reading and A 1. Large Parsnips of the Tender and True variety were prominent and other subjects worthy of special note were Broccoli Christmas White, Savoy Selected Drumhead, Celery Superb Pink and Solid White; Beet Blood Red, Carrot Early Gem and Brussels Sprouts Dwarf Gem and Fillbasket, small and large varieties respectively. Variegated Kales were used as decorations.

Messrs. G. Bunyard and Co., Ltd., showed fifty-two varieties of Apples, all of exceptional quality, the fruits being large and highly-coloured. A selection of the best sorts includes Chas. Ross, Ribston Pippin, Cox's Orange Pippin, Blenheim Pippin, Belle de Boskoop, Heusgen's Golden Reinette, Wagener, Sturmer Pippin, Autumn Pearmain, Adams's Pearmain, Allington Pippin, Rival, Wealthy, Ontario, Rev. W. Wilks, Lane's Prince Albert, Bramley's Seedling, Byford Wonder, Norfolk Beauty, Blue Pearmain, and Allen's Everlasting.

Mr. T. Ernest Waltham, 97, Upper Tulse Hill, S.W. 2, displayed remarkably faithful models of Bramley's Seedling and Newton Wonder Apples done in a composition like rubber and perfectly indestructible. Fruit growers were much interested in these models, which could be made to serve a variety of useful purposes.

GARDENING APPOINTMENTS.

Mr. F. Manfield, for the past ten-and-a-half years Gardener to Col. G. H. Trollope, Fairmile Hatch, Cobham, Surrey, as Gardener to R. Bennett, Esq., at the same place. (Thanks for 2/6 for R.G.O.F. Box.—Eds.).

Mr. J. Mitchell, as gardener to Lieut.-Col. Sir G. L. Holford, K.C.V.O., at Westonbirt, Tetbury, Gloucestershire.

MARKETS.

COVENT GARDEN, Tuesday January 12th, 1926

Plants in Pots, etc.; Average Wholesale Prices.

(All 48's except where otherwise stated).

—large, 60's	5 0- 6 0
—small	4 0- 5 0
—72's per tray of 15's	2 6- 3 0
Roman Hyacinth, on bulbs, per doz.	4 6- 5 0

Remarks.—With the exceptions of Richardias (Arums), Lilium longiflorum and L. speciosum, there has been a considerable increase of most subjects notably of White Azaleas, Carnations, Daffodils, Freesias, Forget-me-nots, Narcissus Soliel d'Or, Narcissus Grand Primo, Tulips, which are much improved in quality, Violets and White and mauve Lilac. Lilium longiflorum has advanced considerably in price owing to the supply becoming suddenly short. The first consignment of Daffodils was received from the Spalding district last week; and of Anemone fulgens from the Scilly Isles. Iris tingitana and Snowdrops are also available. Larger consignments are being received from the Channel Islands and also from the south of France. The prices of these imported flowers are on the down grade; their quality, generally, is good. Some very fine red Roses of the Ulrich Brunner variety are being received from the south of France. Holland is sending in addition to Lilac, Prunus, Lily-of-the-Valley and Tulips in variety.

Remarks. Business has not been altogether unsatisfactory for the time of year, a fair volume of trade having been transacted. The earlier shipments of fruits from South Africa are meeting a steady demand, Peaches, Apricots and Plums being generally in good condition. Imported Apples are meeting with a poor trade, Jonathan and Newtown particularly, as a result of the arsenic scare. A few good English Blenheim Pippin, and Cox's Orange Pippin are realising comparatively good prices, while there seems also a better tendency in the trade for large cooking Apples. English Grapes are not quite so plentiful, but their prices show little variation. Oranges are not selling freely, and Bananas are a quiet trade. Forced Beans from Guernsey and Worthing are scarce and dear. New Potatos from Guernsey, the Azores, Canary Islands and Algiers sell very slowly indeed. Asparagus, both French and home-grown, is also a bad trade, and even at low prices. Seakale is more abundant and quoted at lower rates. Forced Rhubarb has appeared in quantity very rapidly, but is selling comparatively well. Mushrooms seem to be an improving business. Tomatos from the Canary Islands show a considerable variation in quality and condition, with a corresponding range of values. A few Cucumbers are arriving, mainly from the Worthing district, and are selling at high figures. Heavy shipments of Cauliflower from northern France have been arriving lately, and, except where they have been out of condition, have sold very well. Lettuces and other salads from France have been an important section during the past few weeks, and have sold well throughout. Green vegetables are a fair business at steady rates. The trade in old Potatos remains stable, with good sorts in demand.

GLASGOW.

The New Year markets were under the influence of the holidays, and notwithstanding that supplies of cut flowers were on a much smaller scale. Prices moved irregularly, with a sharp decline in some subjects. This tendency was reflected particularly in Carnations, Lilium longiflorum (Harrissii) and Richardias (Arum) which were only worth from 4/- to 5/-, as against 8/- to 10/- in the preceding week. Roses ranged from 5/- to 8/- per dozen, and were cheaper than they have been for several weeks. Chrysanthemums are nearly over for the season; the only varieties on sale were Heston White and Winter Cheer. Small blooms made 8d. to 1/-, and large, 1/- to 1/9 for 6's. Tulips were more plentiful, and the different varieties were disposed of as follow:—W. Copland, 3/- to 4/- per dozen; Prince of Austria and Vermilion Brilliant, 2/- to 3/-; Murillo, 2/- to 2/8; Rosina, 2/6 to 3/4; La Reine, 3/- to 4/-; and Thomas Moore, 1/8 to 2/6. Golden Spur Daffodils brought 1/6 to 2/- per bunch, while Narcissi kept fairly steady at 4/- to 5/- per dozen bunches. Hyacinths were more easily moved, white medium realising from 8d. to 10d. for 3's.; specials, 1/- to 1/2; pink, 10d. to 1/4, blue, medium, 8d. to 10d.; and specials, 10d. to 1/2. Lily-of-the-Valley averaged 2/- per bunch, and English Violets were also down at 1/6 to 2/-. Bowls of Hyacinths and Tulips were worth from 1/6 to 2/-.

A quieter business was transacted in the fruit market, and values of Oranges and Apples moved in favour of buyers. A cargo of Valencia fruit arrived in the Clyde in defective condition, and at the auction sales cases of 300's and 360's were sold so low as 5/- to 6/-. As a result of a stormy passage large numbers of cases were damaged by salt water. Counts of ordinary quality were quoted as follows: 300's, 9/- to 13/-; 360's and 504's, 11/- to 13/-; 420's, 17/- to 24/-; 714's, 16/- to 19/-; and 1060's 18/- to 21/-. Murcia 360's brought 9/- to 10/6; and 300's 10/- to 14/-. Messini Lemons, 300's, ranged from 10/- to 12/-; and Murcias, from 14/6 to 18/-. Grape Fruits was slightly down at 21/- to 23/- for Porto Rico brand, and 29/- for Blue Goose. Apples: American Winesap, 11/6 to 14/- per case; Delicious, 11/- to 16/-; Oregon Newtown, 12/- to 17/6; Spitzbergen, 11/- to 13/6; Jonathan, 9/- to 11/-; Winter Banana, 12/- to 14/-; and Rome Beauty, 10/- to 12/-. Virginia:—Ben Davis, 16/- to 20/- per barrel; Gano, 16/- to 19/-; York Imperial, 27/- to 31/-; Winesap, 30/- to 35/-. Canadian:—Kings, 28/- to 31/-; Baldwin, 18/- to 24/-; Spy, 24/- to 27/-; and Greening, 27/- to 31/6. English: Bramley's Seedling, 16/- to 20/-. Winter Nelis Pears, Californian, 15/6 to 17/6 half-case; Washington, 8/- to 12/-; Oregon, 16/- to 20/-; Beurré d' Anjou, 6/- to 8/-; Doyenné du Comice, Oregon, 15/- to 20/-. Mandarins sold at 1/- to 1/3 per tray, and 16/- to 22/- per case. Scotch Tomatos made 8d. per lb for firsts, and 4d. per lb for best quality. Mushrooms declined to 1/6 per lb. Grapes remained steady: English Gros Colmar sold at 1/6 to 2/6 per lb; Scotch, 1/6 to 3/-; and Belgian, 1/- to 1/3.

ANSWERS TO CORRESPONDENTS.

Chrysanthemums Diseased. — *T. L.* The fungus present on your Chrysanthemums is the common grey mould, Botrytis cinerea. All dying parts of the plant should be removed and burnt. All decaying vegetable matter in the vicinity should also be removed, as the fungus lives on this and spreads to cultivated plants. As much fresh air as possible should be admitted to plants when they are growing indoors, having due regard to the weather.

Cherry Shoots Retaining their Old Leaves.—*Constant Reader.* The disease is known as "Cherry Leaf Scorch," and is caused by the fungus Gnomonia erythrostoma. This fungus enters the leaf-stalk and prevents the leaves from being thrown off in the autumn. On the dead leaves fructifications are formed with spores that infect the young leaves the next season. If all the dead leaves are removed in any one season, the tree will be quite healthy again. If this is impossible, spraying twice with Bordeaux mixture just before and after the flowering season, will control the disease.

Unhealthy Apple Trees.—*W.* From the brief description you give of your Apple trees dying back, it would appear that the roots are not in a very healthy state. If the roots are starved for want of food, canker, mildew, and other diseases will soon attack the weakest trees. Examine the roots and supply them with necessary food to encourage healthy growth, when these diseases will disappear. Potash alone will not cure or prevent the shoots dying back, but sulphate of potash may safely be used at the rate of two ounces to the square yard, and kainit at double the amount.

Plant Introductions to the United States.

THE Bureau of Plant Industry of the United States Department of Agriculture, in issuing its fourteenth annual list "of the more important introduced plants now ready for experimenters," has laid gardeners of all countries who see the publication under a heavy debt of gratitude. Gardeners in the United States who are willing to experiment with the plants enumerated in the list, may apply for and receive specimens with the sole obligation of supplying the Federal Horticultural Board in due season with a report on the result of their experimental cultivations. The scheme is an admirable one. It encourages the spirit and habit of experimentation and in due course it must lead to United States gardens becoming the homes of vast numbers of plants from all parts of the world. In the long run, moreover, the results of these periodical distributions of plants of promise will be bound to throw light on the extent to which plants are susceptible of acclimatisation. Many gardeners, it is true, accept acclimatisation as a fact. They assume that cases are known which prove that a plant taken from its habitat may gradually become accustomed to a very different one. A mesotherm, for example, that is, a plant which lives naturally in a relatively low temperature, may upon this hypothesis be gradually acclimatised to live happily at lower temperatures. Yet any one who will review the evidence in favour of acclimatisation, at all events with respect to temperature, is likely to be sceptical as to the extent of the powers of plants to accommodate themselves to new conditions. No one, of course, denies that many plants possess considerable elasticity of power of accommodation. But that is neither here nor there. What is wanted are experiments which show that by gradually subjecting a given species to more severe conditions, e.g., of temperature, it becomes able to live in places where, had it been brought thither forthwith without preliminary and gradual "hardening," it would have died. Experiments of this kind have been made, and made successfully, with certain of the lowest kinds of plants—Bacteria. Species of Bacteria which habitually live within a given range of temperature may be cultured and sub-cultured until, by degrees, they are able to resist either lower or higher temperatures than those which fall within their natural range. With respect to flowering plants, however, we know of no experiments which may be said to demonstrate unequivocally that the higher plants possess any powers of gradually responding to changed conditions so that they become able to grow in regions which were originally too hot or too cold for them. It would seem indeed, that each kind o plant possesses a certain power of cold resistance some more and some less—and that this power remains unaltered. If it is, as we say, tender—tender it remains. If this be indeed true, it is remarkable; for there is no doubt but that plants do possess considerable powers of adjustment to other conditions of environment, particularly those of light and water-supply. These, however, are but reflections called forth by perusing the list of plant introductions already referred to. There are others also, and of a kind which gardeners of all descriptions may share. They are akin to those evolved by reading the fascinating catalogues of plants which it is their pleasure to receive at this time of the year. Who has not had his hopes and imagination quickened by reading these catalogues. The day's work is done. The early evening is closing in. The bare places of the garden have shown themselves in their mid-winter conspicuousness. And here are the plants which should fill them The appeal of the catalogue at such a time is irresistible. So on reading this list the gardener may, at all events, allow his imagination to picture how some of these plants, available to American gardeners, might thrive with him. In the list are fruit trees, new Peaches, Nectarines, and Apricots from China and elsewhere, some of which might, perchance, prove hardier than those he grows under the not too sure shelter of walls or hedges. There are flowering shrubs, some of which, however, we already know; others that we should like to know—Buddleia Forrestii, for example, which is likely to prove hardier than B. Colvillei, and lavender-blue flowered, with leaves covered with white woolly hairs. There is the beautiful autumn-flowered Clematis tangutica obtusiuscula, which was presented by the Hon. Vicary Gibbs, and Cornus capitata, which to see named here reminds us of Cornish gardens and such-like favoured places where only in these islands is it to be seen in full beauty. A new species—or at all events one yet unnamed—of the handsome Loquat (Eriobotrya), so rarely grown and yet so fine an ornament on a wall, and a Koelreuteria, K. formosana, a handsome tree from Japan, but likely to prove tender in frosty places are in the list. The handsome Ligustrum Delavayanum is mentioned and deserves to become popular in the States and here because of its prostrate habit, the handsome setting of its foliage, and its blue-purple fruits; also a Photinia, as yet unnamed, this, too, from China, with red leaf stalks and mid-ribs, white flowers, and rich crimson fruits. There is also a Poplar, Populus Maximowiczii, a stately Chinese tree growing in the coldest, poorest, and driest of soils, with handsome wrinkled leaves like those of a Rosa rugosa, which last long on the tree. And so we read through the interesting list and at the end make one more reflection, namely, that here at all events is some amends made by the Federal Board to American horticulturists from the limitations that by import restrictions it has imposed on them in the way of obtaining plants from commercial growers in Europe.

Gold Veitch Memorial Medal for Alpines.—The Council of the Royal Horticultural Society has decided to offer a Gold Veitch Memorial Medal for the best exhibit of Alpines in pots and pans staged by an amateur at the Society's fortnightly show on 23rd March, 1926.

Appointments.—Mr. J. S. King, who for some years was lecturer in book-keeping, and for the past eighteen months has been advisory economist at the Midland Agricultural and Dairy College, has been offered a similar appointment at University College, Reading. Mr. A. Broadfoot, an assistant to Mr. King, has been appointed County Organiser for West Perthshire.

The Gardeners' Royal Benevolent Institution.—The eighty-sixth annual general meeting of the members and subscribers to this horticultural charity will be held at "Simpson's," 101, Strand, London, on Tuesday, January 26, 1926, at 3 o'clock p.m., for the purpose of receiving the report of the committee and the accounts of the institution (as audited) for the year 1925, electing officers for the year 1926, and for the election of twenty annuitants on the funds. The chair will be taken by Leonard Sutton, Esq., J.P., C.B.E., Chairman of Committee, at three p.m. The poll will be open at three o'clock and close at four o'clock precisely, after which hour no voting papers can be received.

Botanical Magazine. — Eleven plants are illustrated and described in Vol. CLI, Part II (1925), of the *Botanical Magazine*. Clerodendron Colebrookianum, t. 9082, is a native of the Khasia Hills, India, and has long been cultivated in the Temperate House at Kew, where specimens planted out flower and fruit regularly every year. The inflorescence comprises numerous corymbs of white flowers which are succeeded by ornamental fruits, the persistent calyces which support the latter being scarlet. Rhododendron anthosphaerum, t. 9083, is one of the newer Chinese species with a striking inflorescence of deep rose-coloured flowers. The species was discovered by Mr. Forrest, who states that it makes a small tree of some twenty to thirty feet. Apparently Forrest met with two forms of the plant; the one of his first collecting was named R. anthosphaerum by Prof. Dills, the other R. hylothreptum by Sir Isaac Bailey Balfour and Prof. W. W. Smith. The difference between the two plants, however, is so minute that they are considered to be identical. Roscoea cautleoides, t. 9084, is a plant that has been shown on several occasions and described in *The Gardeners' Chronicle* (Vol. LIX, p. 300, and Vol. LXVII, p. 101). The colour of the flower varies—lemon-yellow or rose, deep purple or white. The plant is perfectly hardy and grows best in soil containing lime, leaf-mould and sand. Buddlea alternifolia, t. 9085, like most members of the genus, is a useful garden shrub and perfectly hardy in this country. The flowers, developed in clusters along the slender, curving shoots, are reddish-purple with an orange eye. It will be noticed that Buddlea is spelt without the usual "i"; Dr. Stapf remarks that the plant was named in honour of Adam Buddle, the botanist, and Buddlea, is, he states, obviously the correct spelling, as used by Sprengel in 1809. Catasetum. tenebrosum, t. 9086, was first described by Kränzlin in *Gard. Chron.* Vol. XLVIII. p. 229. The many-flowered raceme of this Orchid is very striking, the flowers being chocolate brown with honey-coloured markings on the lip. × Malvastrum hypomadarum, t. 9087, was first illustrated and described in *Gard. Chron.* June 20, 1908, by Mr. T. A. Sprague, who regarded it as a species. It is apparently a very old plant for there is a specimen in the herbarium of the British Museum dating, at latest, from 1795. The plant is now regarded as a cross between M. capense and M. scabrosum. It is a decorative subject for the conservatory (see *Gard. Chron.*, August 1, 1908, Fig. 34), and easy of cultivation; Aconitum anglicum, t. 9088, is a showy Monkshood, found wild in parts of the south and south-west of England and the adjoining parts of Wales. It is closely allied to A. Napellus, and Dr. Stapf states that it matters little if we speak of it as A. anglicum or A. Napellus anglicum. The illustration of Berberis Vernae, t. 9089, shows a flowering branch of this species with short, columnar racemes of yellow flowers developed from each fascicle of leaves. The foliage on the shoot is entire and spathulate, but the illustration of the spray with fruits shows the leaves broader and spinously dentate. The fruits are like small Red Currants. Itea ilicifolia, t. 9090, was described and illustrated in these pages (*Gard. Chron.*, August 5, 1911, Fig. 46), when it received the R.H.S. Award of Merit. It is a useful evergreen shrub or small tree for small gardens and produces long pendulous racemes with brownish-yellow flowers. The leaves are glossy and toothed, very much like Holly leaves. Papaver commutatum t. 9091, has been described on frequent occasions in *Gard. Chron.* under its synonym of P. umbrosum; in other works it has been described as a variety of P. Rhoeas, which it resembles both in flower and foliage. It is said to be as easy to grow as the common Poppy and there are double forms. Geranium Farreri, t. 9092, is a Chinese species; a low, perennial herb with opposite, reniform leaves and dainty flowers faintly suffused with pink and having bluish-purple anthers.

Some Practical Aspects of Botany.—Under the auspices of the Botanical Society of Edinburgh, Professor J. M. F. Drummond, M.A., F.L.S., of Glasgow University, delivered a public lecture in the Royal Botanic Garden, Edinburgh, on the 15th inst., entitled "Some Practical aspects of Botany." After briefly reviewing the evolution of botanical science to its present dimensions, the lecturer proceeded to consider the factors making for success in the growing of agricultural crops. These factors were three in number: (*a*) The nature of the crop plant; (*b*) soil conditions, which affected the nature of the plant, and (*c*) weather conditions. After a few remarks on the last factor, which at present is almost beyond control by the farmer, the lecturer dealt with the other two factors in greater detail. He instanced the case of the root nodules on Leguminoseae as an example of how soil conditions affected the crop plants, pointing out that certain genera appeared to have their own strain of the Bacillus radicicola, which was responsible for the nodules, and that unless the soil contained these bacteria, the plants would not attain to their maximum development. Dealing with the first factor, he emphasised the importance of the pure-line breeding discovered by Shirreff, Johannsen and others, and the value of Mendel's work in plant breeding.

Rev. Hilderic Friend.—Over a long series of years the name of Hilderic Friend has been familiar to readers of *The Gardeners' Chronicle*, as he has been one of our most valued contributors. Widely travelled, widely read, gifted with a wonderful memory, possessing a genius for the study of the smaller created things, and a remarkable knowledge of the derivation of words, it is small wonder that his contributions find general acceptance and appreciation. During a stay of many years in the far East, the Rev. Hilderic Friend studied natural history and oriental languages, thus laying up great stores of knowledge which have formed the groundwork of his erudite articles on "Garden Craft in the Canticles," "The Garden in Antiquity," "Classical and Legendary Gardens," etc. Owing to ill health and an accident to his left eye, Mr. Friend was compelled to return home from China and to spend much of his time in the open air. This led him to make a closer study of nature, with the result that he was peculiarly well-fitted to write such interesting books as *Flowers and Flower Lore*, *Glossary of Devonshire Plant Names*, and others of similar character. In 1890, he began that study of annelids which has brought him considerable fame in the world of natural history. For thirty-five years he has continued this study, adding many new species to our list of native Oligocheats. In 1914, he undertook research work for the Board of Agriculture at the Birmingham University with a view to determining the relation of white worms (Enchytraeids) to diseases of plants. In addition to his articles in *The Gardeners' Chronicle*, Mr. Friend has contributed to the *Journal of the Microscopical Society*, *Science Gossip*, the Linnean and other societies, descriptive articles on the new species, action and life histories of British worms, and quite recently he wrote his interesting *Story of the British Annelids* and *British Earthworms and how to Identify them*. He also acted as referee on the subject of worms for the *Irish Naturalist* during the thirty-one years of its existence, and has acted in a similar capacity for the authorities at the Royal Gardens, Kew, and other institutions. Mr. Friend now lives in retirement from official duties, but continues his researches purely out of love of nature, and we trust he will be spared for many years to contribute to our columns.

REV. HILDERIC FRIEND.

Germination of Seed Peas.—The Ministry of Agriculture points out that the regulations made under the Seeds Act, 1920, require in the case of a sale of seed Peas, that the seller shall deliver to the purchaser a statement in writing containing certain specified particulars including (1) the name and address of the seller; (2) a statement that the seeds have been tested in accordance with the provisions of the Act; (3) the kind of seed; (4) the percentage of purity if below ninety-seven per cent.; and (5) the percentage of germination; provided that if the percentage of germination is not less than the authorised minimum percentage of germination prescribed in the Schedule to the Regulations (viz., seventy per cent), a statement to that effect which shall include the authorised minimum percentage of germination, shall be sufficient. As was the case in 1924, there are indications that the germination of the 1925 crop of seed Peas is below normal and that consequently a considerable proportion of the Peas marketed this season will be found to germinate slightly less than the minimum percentage prescribed in the Seeds Regulations. The sale of seed Peas with a germination of less than seventy per cent. is not contrary to the Regulations, provided the actual percentage of germination is declared. To avoid failures in the crop, it is advisable that seeds testing less than seventy per cent. should be sown rather more thickly than usual.

British Mycological Society.—The programme of the meeting of this Society to be held at University College, Gower Street, W.C., on Saturday, January 23, at 11 a.m., is as follows:—Mr. B. Barnes will make "Preliminary Observations on the Physiology of Lachnea"; Mr. A. Chaston-Chapman will put forward "A Plea for a National Institute of Industrial Micro-Biology"; Messrs. Kodak, Ltd., will demonstrate the Eastman Colorimeter; Mr. J. Ramsbottom is to contribute "Fragmenta Mycologia V"; Mr. G. Tandy will discuss "The Cytology of Pyronema domesticum, Sacc.; and Mr. W. M. Ware will give an account of "Pseudoperonospora Humuli and its Mycelial Invasion of the Host Plant." Members are invited to bring exhibits. Lunch will be arranged in the College Refectory.

The Germination of Rose Seeds.—The difficulty raisers of new Roses have in germinating the seeds was referred to by Dr. William Crocker at a meeting of the American Association for the Advancement of Science, held at Kansas City on the 28th ult. He stated that Rose-breeders have always had a great difficulty in getting good germinations from seeds of hybrid Roses, and some of the species also give very poor results with the ordinary method of seed-raising. It was stated that the late Dr. Van Fleet, the famous U.S.A. rosarian, used to retain his beds of hybrid Rose seeds from five to seven years, a seedling appearing now and then during this long period. Dr. Crocker stated that the temperature of the seed-bed is of paramount importance. The best temperature is about 5° C. and either 0° C. or 10° C. is ineffective The stratification medium or seed-bed is also of much importance. Granulated peat, he said, was a much better medium than sand. After the seeds had begun to germinate at 5° C., the percentage of germinating seeds is increased by a monthly period of transfer from three to five days in a temperature of 20° C, It was found that the seeds of different species of Rosa show a great variation in their development. Under the treatment advocated, seeds of Rosa multiflora required two months to germinate, those of R. rubiginosa and R. rugosa, three to four months, and R. Manettii, eight to nine months.

Flinders Chase, Kangaroo Island.—Flinders Chase, a reserve comprising some two hundred square miles at the western end of Kangaroo Island, South Australia, was set aside as a sanctuary—a flora and fauna reserve—by the Government of South Australia by Act of Parliament in 1919. In a brief account given at the recent meeting of the Linnaean Society Professor F. Wood-Jones, F.R.S., stated that the administration of the reserve is carried out by a small Board, of which the lecturer is the honorary secretary. The work carried on by the Board was outlined, and some account of the fauna and flora was given. Funds for the Chase have to be raised by the Board, and on all moneys collected the Government grants a pound for pound subsidy. It is intended that the Reserve shall function, not only as a sanctuary, but as a depôt for the legitimate supply of scientific material to workers in Australia and other lands, and for the furnishing of living animals to zoological gardens, specimens to museums, and pelts to the fur market. In this way the Board is confident that ample revenue can be raised for much needed work upon the Chase, and granted a continuance of public goodwill and proper political support, it may be safely predicted that Flinders Chase will rank among the important sanctuaries of the world, and be a cherished possession of South Australia when the terrible depletion of the indigenous fauna and flora, which is proceeding on the mainland, has robbed Australia of its unique zoological and botanical interest. Considerable progress has already been made in the direction of introducing on the Chase those species which are in most immediate danger of extermination in continental Australia, and this policy will be steadily continued so far as opportunity and funds permit. A series of lantern slides illustrating the topography and some of the animals and plants of the Chase was shown. The president, Dr. Rendle, and Dr. A. W. Hill, F.R.S., followed with observations which led to the following resolution being unanimously adopted :—"That the Linnaean Society in general meeting assembled having heard with great interest and pleasure the account by Professor Wood-Jones of the Flinders Chase Reserve on Kangaroo Island, desire to express their appreciation of the work which is being done for the preservation of this portion of the South Australian Fauna and Flora."

Orchids in a Public Park in U.S.A.—In the West Chicago Parks is a collection of Orchids, comprising between 3,000 to 4,000 specimens, representing over 400 species and varieties, and including many rare hybrids. Recently, a number of Cymbidium hybrids were imported from England under a special licence, to add to the collection. On the occasion of President and Mrs. Coolidge's visit to Chicago last month a bouquet of Orchids, from the Chicago Park collection, was presented to Mrs. Coolidge by Dr. John Dill Robertson, President of the West Chicago Parks Commissioners.

A Useful Diary.—The *Year Book and Diary* issued by the *Fruit, Flower and Vegetable Trades' Journal* is a very useful publication with ample space on the pages in which the days of the weeks are recorded, for making notes, and with ruled columns for monies received and paid. These pages are interleaved with blotting paper, so that the diary may be made to serve as a blotter in addition to its other uses. Much valuable information to those interested in the fruit and vegetable trades is given in the text on such subjects as monthly operations in orchards, market gardens and nurseries ; suitable washes for fruit trees ; the constituents of fertilisers ; the best market varieties of fruits ; the various insects and pests Orders ; statistics as to imports of fruits, vegetables and flowers ; and other valuable data. The *Year Book* is published by the Lockwood Press, 1, Mitre Court, Fleet Street, London, price 2/- net.

The late Mr. W. R. Dykes.—The late Mr. W. R. Dykes, Secretary of the Royal Horticultural Society and for sixteen years a Master of Charterhouse, left an estate of the gross value of £8,605, with net personalty £4,710.

South African Fruit Trade.—During the past twelve months South Africa exported 1,497,181 boxes of fruits other than Citrus varieties, 450,218 boxes of Citrus fruits, and 68,464 boxes of Pineapples ; these figures show a considerable increase over those for 1923-24. The new feature of the export trade has been the carrying out of extensive experiments in the transportation of fruits from the Transvaal to the coast, for export. By the use of refrigerator cars, fruits pre-cooled in the Transvaal and transported in the refrigerator cars may be exported with profit. The rapid growth of the export trade in Citrus fruits will probably necessitate the provision of cold storage accommodation inland in the near future, and if this accommodation were provided it would meet the needs of the growers of other fruits in the district. The Transvaal fruits have the advantage of reaching the overseas markets before the Cape fruits are ready, and when there are no other fruits of the kind available.

Forthcoming Lectures.—At the meeting of the Royal Society of Arts on Wednesday, the 27th inst., at 8 p.m., Professor John McLean Thompson, D.Sc., will deliver the Aldred Lecture for 1925-26, his subject being "Some General Problems of the Transport by Sea and Conservation in Store of Ripe Fruit."—A lantern lecture will be delivered by Capt. H. C. F. Macdonald under the auspices of the borough of Bermondsey in co-operation with the Bermondsey and Rotherhithe Horticultural Society, on "Lawns and Ornamental Grasses," on Wednesday, January 27, at 7.45 p.m., in the Council Chamber, Bermondsey Town Hall.

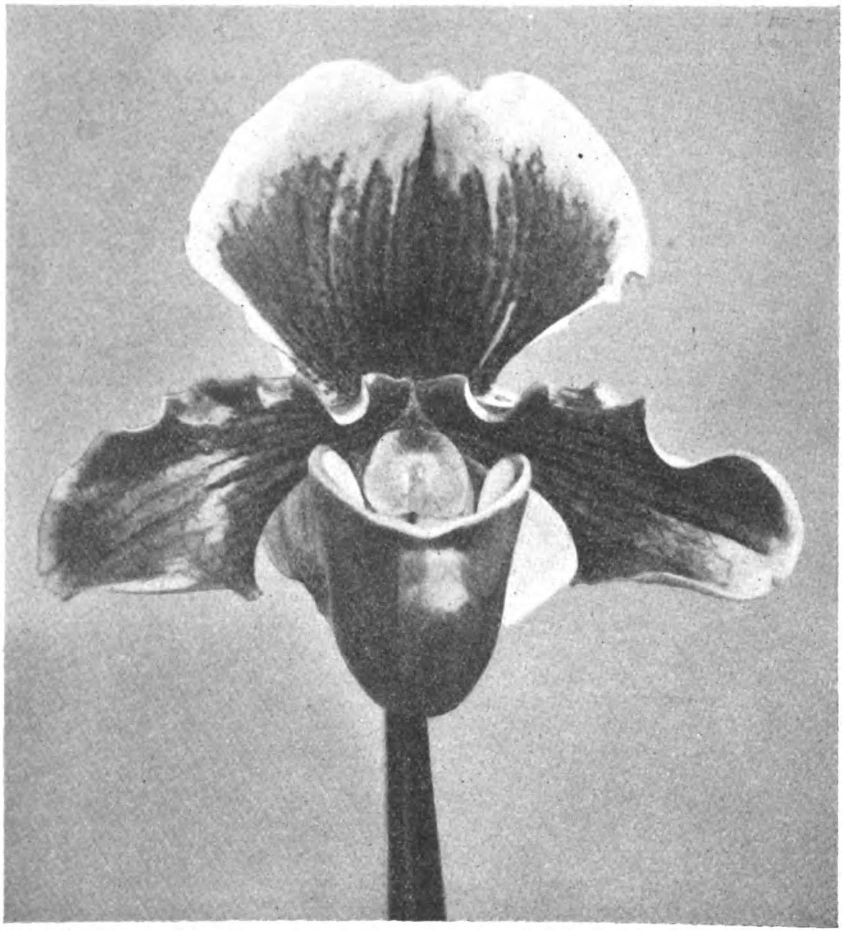

FIG. 29.—CYPRIPEDIUM CHRISTMAS CHEER.

R.H.S. First Class Certificate, January 12. Flowers deep purplish red, white and green. Shown by Mr. Robert Paterson, Glasgow (see p. 52).

Appointments for the Ensuing Week.—Tuesday, January 26 : Royal Horticultural Society's Committees meet ; Gardeners' Royal Benevolent Institution's annual meeting at Simpson's Restaurant, Strand. Wednesday, January 27 : Wimbledon Gardeners' Society's meeting. Thursday, January 28 : Paisley Florists' Society's meeting ; Brighton, Hove and Sussex Horticultural Society's annual meeting. Friday, January 29 : British Florists' Federation annual meeting and dinner at Holborn Restaurant ; Association of Economic Biologists meet

"Gardeners' Chronicle" Seventy-five Years Ago.—*Earthing-up Vegetables.*—Mr. Cuthill, in his very interesting and instructive papers on "Market Gardening round London," tells us that Cabbage plants "are never earthed up—a bad practice for almost any crop." The principal use of moulding up to growing plants is to steady them, and where the soil is light and the situation is exposed to strong winds, that process is absolutely necessary ; at least, I find it so, and have never observed it in any way injurious to the Cabbage tribe. Late Broccoli I mould up with a vengeance, my practice being to take out every row in the autumn and lay them down in the usual way ; those that remain, being then four feet apart, have the soil from between the rows banked up (like earthing Celery) so as to cover the whole of the stems up to the lower leaves, which enables the plants to stand erect even in the roughest weather, and also protects them in a considerable degree from the influence of severe frosts. When the stalks are dug up in spring, many of them will have pushed a number of fibrous roots into the soil that surrounded them. I may here mention—for the benefit perhaps of some who, like myself, never have their eyes gladdened by the sight of a two-horse load of dung "emptied down (as if it were a barrowful) for every thirty feet" of ground—that these said Broccoli stalks make a capital dressing for Potatos when chopped to pieces and dug in as manure. In poor, sandy soil, I have found green manure of this kind more beneficial to Potatos than a dressing of the half-decayed leaves sparingly adulterated with stable litter, which many gardeners are obliged to substitute for dung. *J. B. W., Gard. Chron., January* 25, 1851.

The Week's Work.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Dendrobiums.—March and April are usually regarded as the flowering period for deciduous and semi-deciduous species of Dendrobiums and their hybrids. Many of the plants have commenced to push forth their bloom buds, and if it is desired to extend the flowering season, a few of the more forward specimens may be removed from their resting quarters to a house having a slightly higher temperature, and afforded a slight increase of water at the roots. A careful selection is necessary, both in regard to varieties and the condition of the plants. Only well-rooted and thoroughly ripened specimens with the most advanced flower buds should be chosen, giving preference to those of the D. nobile and D. aureum type, and hybrids from these species. The increase of both heat and moisture should be gradual. Little water at the roots will be needed for some time, the object being to cause the flower buds to swell without exciting the plant into growth, as this would cause the buds to turn yellow and drop, or the flowers to be of inferior quality. The plants should be first placed in a house where the temperature is a few degrees warmer than that in which they have rested, finally transferring them to the stove or warm division.

Forcing Dendrobiums.—Unless early flowers are especially desired, forcing should not be hurried; only sufficient warmth should be employed to cause them to develop slowly. With this treatment, the flowers will be of larger size and of greater substance than when much fire-heat has been employed. Keep a sharp watch for slugs which damage the buds so soon as they begin to develop. Traps of damp bran or Lettuce leaves should be placed about the stages near the plants, and the pests searched for at night time and in the early mornings.

Tall-growing Dendrobiums.—Dendrobiums of the tall-growing species, which include such as D. fimbriatum and D. moschatum, should still be resting, and allowed to remain dormant for the next two months. D. Dalhousieanum and its hybrids should be grown in the warmest house at all times, and not kept excessively dry at the roots during their resting season.

FRUITS UNDER GLASS.

By T. PATEMAN, Gardener to SIR CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

The Cold Orchard House.—Trees growing in borders in the cold orchard house, such as Peaches, Pears, Plums and Cherries, should now receive the earliest possible attention with regard to putting them in order for the coming season. Although the trees are somewhat later than usual owing chiefly to the cold winter, it is surprising how quickly their buds expand immediately a spell of mild weather sets in. Very little pruning is necessary at this season of the year, provided the old fruiting wood was cut out immediately the fruits were harvested; what little pruning is necessary should be done forthwith. It is most important to observe cleanliness in both trees and houses, therefore, the trees should be thoroughly sprayed with an insecticide before fastening the shoots in position, and again just before the flowers expand, otherwise vaporise the house with a nicotine compound. The paint-work and glass should be cleansed immediately after the first spraying takes place, and the walls scrubbed before coating them with lime and sulphur. This preparation should be well worked into all crevices; to enable this to be done the mixture should be made into a thin paste.

Top-dressing the Borders.—Immediately the trees and house have received their final cleansing, and the work of tying the shoots is completed, proceed with the top-dressing of the border; but before doing so, remove a small portion of the top soil. If the borders are dry, they should be watered thoroughly, for fruit trees should not be allowed to suffer through lack of moisture at the roots even when they are dormant. This completed, apply a top-dressing of turfy loam mixed with charcoal and bone-meal. Cover this top-dressing with a thin layer of short manure, which will greatly assist the water to penetrate evenly into the soil. Keep the house as cool as possible, to retard growth, by opening the ventilators, night and day, until the flowers are about to expand.

Trees in Pots.—After the trees have been washed and their receptacles made clean, pot trees may be brought indoors and arranged at the usual distance apart. Trees that were overlooked in the autumn for repotting should not be disturbed at the roots now, for it is too late to re-pot them, but they should receive a rich top-dressing. Trees that were potted should have the surface soil removed, and be given a slight dressing of new soil. Keep the house quite cool.

THE KITCHEN GARDEN.

By F. STREETER, Gardener to MAJOR ALBERT PAM, Wormley Bury, Broxbourne.

Jerusalem Artichoke.—This crop pays for far better attention than is generally given it. Select an open site that has been trenched and well-manured, and so soon as the weather and state of the soil permits, plant medium-sized tubers three feet from row to row, two feet apart in the rows and six inches deep. The white-skinned variety has a more delicate flavour than the purple sort.

Asparagus.—Where the convenience for forcing Asparagus exists, fill sufficient heated pits with hot-beds made of three-parts leaves to one-part long litter. When the temperature of the bed has fallen to about 65°, place a light compost, consisting of one-part loam, one-part leaf-mould, and one-part old Mushroom-bed manure on the bed, and plant strong, forcing crowns, spreading out the roots evenly over the whole surface, and covering them with about four inches of the prepared compost. Maintain a moist atmosphere, and a temperature of about 60°, admitting a little air during favourable weather. This method is much to be preferred to the old system of forcing permanent beds.

Young Carrots.—Fill sufficient frames with leaves made thoroughly firm, and on the leaves place about four inches to six inches of finely sifted old potting compost. Draw shallow drills one foot apart and sow the Carrot seeds thinly and evenly. French Horn, Early Gem and Initimable Forcing are excellent varieties for this purpose. Plant a row of an early-maturing Lettuce between each row of Carrots; the Lettuces will be ready for cutting before the Carrots are drawn for use. Water the soil with tepid water and keep the frames close until the seeds have germinated. Keep a sharp watch for slugs, and also a too rapid increase in the temperature by sun-heat, admitting a little air on the leeward side of the lights when necessary.

Seakale.—The crowns of Seakale may be forced in boxes or pots according to requirements. A Mushroom house is undoubtedly one of the best places in which to force and bleach the plants, but forcing may also be done under warm greenhouse stages, provided light is excluded. Water the roots with tepid water at all times. It will be advisable when preparing for forcing to cut off and prepare the planting thongs, tying them in bunches of fifty and placing them in boxes of sand or fine soil in a cold house in which they will start into growth.

PLANTS UNDER GLASS.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

Freesias.—As these plants pass out of flower they should not be neglected if it is desired to grow them on for future use. After flowering them they should be stood in a cool house or cold frame, where they should be given regular attention as regards watering and feeding, to build up strong corms for next season. As the foliage matures and shows signs of dying, water at the roots should be withheld gradually. It is not generally known that Fresias may be raised from seeds and flowered the same season. The seeds may be sown during February or March in a cool house, and with proper treatment the resulting plants should flower the following November. As the seedlings suffer a considerable check from transplanting, the best method is to sow the seeds direct into five-inch pots, afterwards thinning the seedlings to about twelve in a pot. The compost should consist of good loam mixed with sufficient sand to render it open and porous. Freesias should be grown in perfectly cool conditions at all times; they respond to liberal feeding when they have well filled their pots with roots. The shoots should be given timely support, for if they are allowed to fall over they never grow freely.

Forcing Plants.—A sufficient number of plants for forcing, according to the requirements of the establishment, should be introduced to the forcing house. It is a mistake to introduce the majority of these plants to a high temperature, as this generally results in failure, In the case of bulbs, they go blind, while shrubby plants are very apt to drop their flower buds. There are some few plants, however, such as Roman Hyacinths, Paper White Narcissus and Lily-of-the-Valley which may be placed at once in a high temperature without harm resulting. It is always wise, when dealing with forcing plants, to accustom them gradually to high temperatures by first placing them in a house, for a week or more, where the temperature is about 50°. Later they may be placed in a temperature of 60° to 70°. In selecting plants for forcing it is important to use for early-blooming species or varieties that naturally flower early, and as the season advances plants generally will naturally respond more readily to higher temperatures. Shrubby plants should be sprayed lightly several times daily until the flowers begin to show colour. The many beautiful varieties of Ghent Azaleas that are so useful for forcing, very quickly drop their flowers; this may be prevented by the use of floral gum, a drop in the base of each flower being sufficient. While Rhododendrons, including Azaleas and some other plants with good fibrous root systems, may be lifted directly from the ground and forced successfully, it is important that many woody subjects should have been pot grown. Such plants as Pyrus, Prunus and Lilac last much longer in flower if they are grown in pots.

HARDY FRUIT GARDEN.

By W. AUTON, Gardener to VISCOUNT ELVEDEN, Pyrford Court, Woking, Surrey.

Raspberries.—Those plantations which had the old canes cut out in the autumn and were left untied should now receive attention. First make sure that all the supports are sound, and see that the training is carried out to the best advantage. If more canes have been left than are necessary to furnish the space available, remove the weaker ones, allowing each cane ample room to develop its fruits. Where new plantations were made in the autumn, the canes should now be cut down to within about nine inches from the ground. If, owing to delay in planting operations during the autumn, contemplated new plantations were not made, these may still be formed when soil conditions are favourable. For this purpose, young stools furnished with two or three strong canes of last summer's growth should be chosen. These may generally be obtained in sufficient quantity from an old plantation, as an abundance of young shoots is always thrown up from established plants; preference should be given to the stools with good fibrous roots, discarding those with naked, woody ones. Trenches should have been well prepared four feet apart, and the stools may be planted about two feet apart in the rows. After all surface work is completed, both old and new plantations should be given a mulch of decayed manure. Raspberries grow best in a rich, friable loam, and in making plantations on light, poor ground, liberal quantities of organic manure should be incorporated with the soil, and a sprinkling of coarse bone-meal may also be added.

Nuts.—These make a desirable adjunct to the dishes for the dessert table over quite a long period of the year, and are particularly valuable where the household is comprised largely of young people. They thrive in almost any well-drained soil, and frequently succeed where other fruits are unsatisfactory. Planting may still be carried out, and if the soil is very poor it should be enriched with organic manure when preparing for the plantations. The distance between the trees may be ten feet each way, and the bush method of training is generally the most convenient, although they may be grown as standards if desired. When bushes have been formed, they will consist of six or eight branches forming a head. The leading shoots of these branches need to be shortened, more or less, at every winter pruning, with the object of causing the branches to develop laterals over their whole length. The final height of these branches may be from five or six feet upwards, at the will of the grower. The buds containing the female flowers are rather more plump than the wood buds, but the flowers do not appear until considerably later than the male flowers borne on the familiar catkins. If there is an abundance of catkins, which is usually the case, pruning may be completed this month, but if catkins are scarce, it is wise to defer pruning until the female blossoms have been expanded for a few days. In exposed positions, severe frost sometimes injures the catkins, and where this has occurred branches bearing catkins should be taken from more sheltered positions and fixed amongst the bushes where catkins are scarce, as a paucity of pollen means uncertainty in crop.

THE FLOWER GARDEN.

By F. C. PUDDLE, Gardener to LORD ABERCONWAY,
Bodnant, Taly-Cafn, North Wales.

Seed-Sowing.—When Begonias are used for bedding, it is a good plan to raise a number of seedlings periodically to replace the older tubers. The seeds should be sown in pots of light soil and placed in a house having an average temperature of 65°. Lobelias and Verbenas may also be sown and placed in the same house, but so soon as the seedlings are large enough to handle, they should be pricked off and removed to slightly cooler quarters. East Lothian Stocks, Campanula pyramidalis and Delphiniums of the Blue Butterfly type (Fig. 30), require a long season of growth, and early sowing is essential. Delphinium Blue Butterfly is a dainty plant in flower, and being of dwarf habit, is suited as an edging subject in borders. A recently started fruit house is perhaps the most convenient place in which to germinate the seeds of these three plants, but the seedlings should be grown under cool conditions to promote sturdy growth. Meconopsis and hardy Primulas are best sown so soon as the seeds are ripe, but if they have been kept for spring sowing, they should be inserted immediately, and germinated in a temperature of 50° to 55°. If the Primula seeds do not germinate within six weeks, they will probably not do so before next autumn or spring; in such cases the pots may be removed to cool frames, and, later, plunged to the rim in ashes in a shady place out-of-doors.

Rhododendrons.—The introduction of many new species of Rhododendron from China and Thibet, has produced a new era in the cultivation of Rhododendrons, and opened a wider field for hybridisation. In many gardens the raising of seedling Rhododendrons has now become an important feature, and as the result of experiments, various mediums in which to sow the seeds are recommended, chief amongst them, peat moss and a species of woodland moss. Although by the use of such moisture holding materials germination may be accelerated, any advantage gained is usually discounted by the check which ensues when the seedlings are transferred to ordinary soil. When considering the merits of the various methods of seed-sowing, it is well to bear in mind that all plants resent drastic changes of soil, and none more so than Rhododendrons. Consideration should therefore be given to the soil in which the adult plants will eventually be grown, and a proportion of this should be included in the compost provided for the seedlings from their infancy. At the same time, it should be recognised that leaf-mould is the natural rooting-medium of the majority of plants, and especially those of the woodland; therefore, in the earlier stages of growth this moisture-holding material should form the greater part of the compost. At Bodnant, where the collection of Rhododendrons is grown in loam, the compost used for sowing the seeds and for the first pricking out of the seedlings consists of leaf-mould, three-parts; loam, one-part; and silver sand, one part. As the plants increase in size and are put out in nursery beds, the quantity of loam is gradually increased, until they become accustomed to the soil in which the main collection is growing. In the case of species, the time of sowing is governed by the arrival of the seeds from the collectors, but seeds of hybrids may be sown immediately they are ripe, in gentle warmth, and the seedlings grown on in a house having an average temperature of 50° to 55°, with free ventilation at all times.

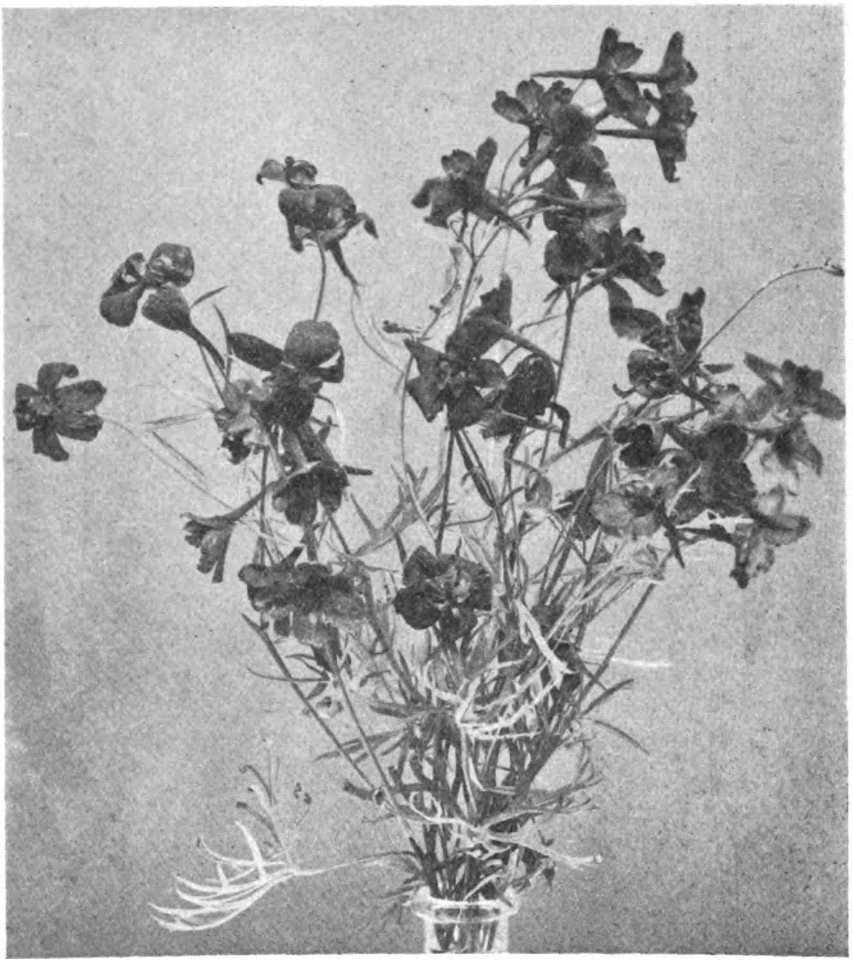

FIG 30.—DELPHINIUM BLUE BUTTERFLY.

FOR NORTHERN GARDENERS.

By A. T. HARRISON, Gardener to the MARQUIS OF
AILSA, Culzean Castle, Maybole, Ayrshire.

Seed-Sowing.—Many varieties of flower seeds should now be sown to obtain the best results, and if only one or two kinds are mentioned that is only an indication of others that may be treated likewise. Sweet Peas, sown in pots now and grown in cool conditions, will make good specimens to plant out in well-prepared trenches towards the end of April. Antirrhinums etc., sown now, will make a display later out of all proportion to the expense involved. Begonias, Gloxinias, etc., sown now in a fairly high temperature, will produce useful flowering pot-plants during August and September.

Gloxinias.—Corms of Gloxinias which have been dried off should now be shaken clear of the old soil and placed in boxes of leaf-mould in a warm house. Keep the corms just moist, applying water sparingly until young growth is in evidence, or the corms may decay. When the second pair of leaves have developed, the plants should be placed in pots of a suitable size. Use a rough, open compost mixed with plenty of good leaf-mould; do not press the soil too firmly, and return the plants to a house having a brisk temperature.

Planting of Shrubs and Trees.—The planting of deciduous shrubs and trees should now be concluded with all speed whenever outside conditions permit. It is too early to transplant the evergreen members, but much may be accomplished during frosty weather by clearing intended sites of undesirable specimens, and carting or wheeling fresh soil, leaf-mould, etc., to the places where they will be required to be ready at hand when planting begins. If the soil is well drained, the sites for choice evergreens may be prepared by deep digging.

IRIS GARDEN.

IRIS UNGUICULARIS.

In a recent note in *The Gardeners' Chronicle* I commented on the extraordinary floriferousness of this beautiful Algerian Iris during the present season and suggested that apparently the greatest factors in bringing about this result are partial starvation and dryness at the root. This production of flowers has continued and increased since the date of my note to such a remarkable degree that the behaviour of the plants seems worth recording. While the border supplied about half-a-dozen flowers weekly during the month of October, we had two or three dozens weekly in November. In spite of a period of weather with abnormally low temperature, this number of flowers was well maintained until Christmas.

That the conditions prevailing during this period were not particularly conducive to growth is strikingly shown by a study of the average mean temperatures recorded here during the eight weeks preceding Christmas. These readings are :—beginning with that of the week ending November 7, and followed in succession by those of the next seven weeks :—50.1°; 36.4°; 40.8°; 37.1°; 34.1°; 40.3°; 34.5°; 36.5°. Nevertheless, during this period more than two hundred flowers were gathered. With the return of kindlier weather conditions, the flowers began to increase at a marvellous rate in the last week of December till a weekly output of about five hundred had been reached, and on January 5, I counted four hundred fully expanded flowers on the border, and the total production to that date exceeded a thousand flowers.

To make it clear to readers what this output means, it will be necessary to give the area of the border and some details of cultivation may also be interesting.

The border is three hundred feet long but only twelve inches wide, and is situated at the foot of a south wall. The plants have been growing in the same position since 1909, and were last disturbed in 1921, when the old plants were lifted, divided and replanted immediately after the flowering period, that is, about the beginning of April. The plants were thoroughly watered and mulched after planting, and under normal conditions no further watering would have been given, but owing to the abnormal drought of that season, two subsequent waterings were necessary between April and midsummer, after which date no further waterings were given. During subsequent years neither watering nor feeding have been practised.

A collection of climbing plants is grown on the wall, many of which are exceedingly good specimens, overhanging the Iris to a considerable extent and lessening the amount of water accessible to them from normal rainfall. Immediately in front of the foot-wide border is a paved path, four feet six inches wide, and on the other side is a herbaceous border. The climbers find their nourishment at considerable distances from the wall and probably the roots of the Iris ramify under the paved path, but it is obvious that this species likes the dryness, warmth and comparative starvation of the position. *W. Auton, Pyrford Court Gardens.*

HARDY FLOWER BORDER.

GILLENIA TRIFOLIATA.

This charming border plant, although long introduced to cultivation and obtained easily from most hardy plant nurseries, is not common in gardens. Why it is not more frequently cultivated it is difficult to surmise. It is not exceptionally showy, but its flowers are exceedingly pretty, while the slender, graceful, yet sturdy habit of the plant itself leaves little to be desired. Its stature is about twenty-four inches, so that the plant is suitable for the small border, and its ability to grow well in shade or partial shade, as well as in sun, is greatly in its favour. The small, white flowers tinged with rose or pink are produced freely.

Although the plant will grow in a situation exposed to the sun, if planted in a sunny position the border should not be too dry, or the plant will not reveal its true beauty. Propagation is effected by division in spring or by seeds, which are procurable from a few seed firms in the British Isles. The seeds may be sown in pots or pans in March or April under glass, or later in the open in sandy soil. The seedlings may be put in their permanent positions in autumn or spring. *S. Arnott.*

LOBELIA CARDINALIS QUEEN VICTORIA.

This is a subject which should be planted freely in the late summer border. Used in combination with Salvia patens and Phlox Tapis Blanc it is always admired, and is perhaps the most vivid, yet refined scarlet flower obtainable.

The cultivation of the plant presents no difficulties, yet many fail to grow it well. The clumps should be lifted from the border during October, and after the old flower spikes have been shortened to within a few inches of the base, planted closely together in a cold pit or frame. The soil should be kept on the dry side during the winter, but by March it should be moistened to have the plants ready for putting out early in April.

If the plants grew with average vigour during the previous summer it will be found possible to divide each old stool into several pieces at the time of planting out. If it is desired to increase the stock considerably, practically every shoot may be utilised for the purpose. These should be placed in boxes of sandy soil, watered and kept somewhat close. When established the plants should be hardened off gradually and planted in the border a few weeks later.

A good, medium, loam suits this half-hardy perennial, the beautiful bronze foliage of which is always attractive in the front of the herbaceous border. Some very fine forms, as well as a variety of shades of colour may be obtained from a packet of seeds of the hybrids. *Charles Hodgson, Acton Place Gardens, Acton, Sudbury, Suffolk.*

FLORISTS' FLOWERS.

DECORATIVE CHRYSANTHEMUMS.

At this time of the year, when flowers are scarce, it is very disappointing to find that certain of the late varieties of Chrysanthemums fail in some cases to produce satisfactory blooms. Occasionally, these defaulters are as satisfactory as could be wished, but at times, for some reason or other, the care and attention which have been bestowed upon them for a whole season are entirely lost.

The reasons generally attributed for the failure is either not rooting the cuttings sufficiently early, or through lack of attention in not giving the plants sufficient stimulants during the latter part of the growing season. Probably either or both of these reasons may account for the trouble, but after experiencing these disappointments, I am inclined to think that it are due to weakness of the variety.

Unfortunately, that otherwise excellent variety, Enfield White, is subject to this weakness, but as it is so good when it does flower, one can hardly discard it.

Among the more dependable varieties may be included The Favourite and its two pink and cream sports : A. J. Balfour, Mme. R. Oberthur, Helena Williams, Mdlle. Louis Charvet, General Nogi, a mauve-pink variety with good strong stems and foliage, Baldock's Crimson and Winter Cheer.

All three of the " Favourites " may be depended upon to produce a large quantity of bloom, even when rooted so late as the end of March.

Amongst the decorative Japanese varieties with long stems flowering in mid-season there are some of outstanding merit, such as Blanche du Poitou, Cream Poitou, M. Julian Valet, Yellow Valet, Sunshine, Golden Marvel and Marne. *T. B.*

RUST ON CHRYSANTHEMUMS.

A simple and sure remedy for rust on Chrysanthemums is paraffin oil used at the rate of a wineglassful to two gallons of water. I have cured three collections of rust in this manner.

When the plants are in their flowering pots and stood in rows four or five feet apart so that each plant can be well syringed, I put a wineglassful of paraffin in two gallons of water, fill the syringe and drive the syringeful back into the pail. Before the oil has time to settle on the surface, I fill the syringe again and spray the mixture on the plants. Every second syringeful is driven back into the pail to mix the paraffin with the water ; this is important.

I have never known any harm done by this specific ; in fact, I think it does the plants good. The plants should be syringed on alternate evenings, weather permitting.

A certain amount of rust will probably appear the following season, but it will eventually die out if this method is persevered with. *Alfred Simeson.*

ALPINE GARDEN.

ERIGERON LEIOMERUS.

Erigeron leiomerus is a delightful subject for a choice, " close-up " ledge in the rock garden or scree. It is one of the smallest members of its race, a New World species, native of the heights of Utah, where it is sometimes intensely cold.

This Erigeron is perfectly hardy, but the drainage should be thorough and full exposure is desirable. It makes a neat little mat of fresh green, rather spathulate, almost hairless, leaves, and above this the inflorescences rise in spring to a height of some three inches. The flowers are a beautifully soft, cool lavender, and about one inch across. In association with a pale yellow-flowered plant, such as Helianthemum Tuberarium or Alyssum montanum, the lovely colouring of the flowers of the Erigeron will be still more appealing.

CORYDALIS CAVA.

This is the earliest of the Fumitories to appear, its finely-cut, glaucous leaves often beginning to show above ground before the Snowdrops. It is a shade lover and appears to delight in cool, mossy corners in woodland. In such places it has, at any rate, done well with me for many years, and it never fails to send up its four-inch heads of purple flowers in early spring. The variety alba is, however, an even more attractive plant when in blossom, its elegant sprays suggesting Roman Hyacinths in the purity of their waxen whiteness and, what is more, in their sweet fragrance, the latter being an uncommon attribute in this genera. Moreover, white is a colour—if the term can be used—which is more in keeping with the first hints of spring than purple, which seems to belong to later days. *J.*

THE ALPINE COLUMBINE

The long-spurred Columbines of hybrid origin are so delightful in every respect that we are liable to overlook the merits of some of the natural species ; Aquilegia alpina is a case in point, yet as a consequence of cross-fertilisation most of the plants grown as Aquilegia alpina are poor and lack much of the charm of the true species. It is a common cause of complaint amongst those who know the genuine A. alpina that the plants in gardens are usually lacking in the intense caerulean blue, and are sometimes even without the large and numerously-lobed flowers of the true species. To keep the seedlings true, the plants should not be grown near other Columbines. I know of a garden in which hundreds of true A. alpina are to be found growing in stony soil, and in richer ground the plant seeds and sows itself so freely that the Columbines require to be cut down ere the seeds ripen to prevent the appearance of seedlings in countless numbers. A close examination of the plants revealed not a single " rogue," not even the one with a white centre, which is reputed to be a variety of A. alpina, but is in reality a hybrid. The best way to establish the true A. alpina is to purchase a small plant in a pot, or seeds, from a reliable firm who will give a guarantee that the plant or seeds are of the true species. *S. Arnott.*

PRIMULA MARGINATA AND ITS HYBRIDS.

I think that of all the European rock Primulas, Primula marginata is the most attractive and the most generally useful in the rock garden. I have found it very abundant in the Maritime Alps, and always as a rock or cliff dweller, usually forming a fringe on the brows of cliffs or of big rocks, on the tops of which humus and vegetation have accumulated. And to accommodate it to this situation in life, it has developed a trunk-like habit, the trunks often slightly branched, and carrying at the tips of the trailing branches, rosettes of leaves. These leaves are very distinct and beautiful. The edges are variously toothed or waved, sometimes deeply and handsomely, and sometimes only slightly, but always the leaf margins are richly edged with a clear line of silvery white meal. The plant is deciduous, losing all its leaves in autumn, the tip of each branch or "trunk" where leaves and flowers had been, resolving itself into a bud for next year's display.

This trunked habit is natural to the plant, but it usually distresses the unthinking rock gardener, especially if he has never seen the plant growing wild, or has not realised that it is the plant's natural habit. It is often stated by writers on such plants that P. marginata is apt to grow leggy, and that to overcome this fault the plant should be top-dressed. In my opinion, this alleged fault is not a fault, but the natural habit of the plant, and need not be discouraged. In fact, I have always thought that the so-called leggy habit of all the trunk-forming Primulas—Auricula, viscosa, hirsuta, and the pubescens hybrids—is, up to a point, an advantage rather than otherwise, in that the trunk carries the leaf rosette well above the soil and out of reach of damp and rot.

Primula marginata is one of the earliest species to flower, often opening its heads of lovely blossoms in March and April. The flowers are carried in a loose head or umbel, five or six or more on a three- or four-inch stem. They are funnel-shaped, deliciously fragrant with the scent of Cowslips, and in colour they vary from cool lilac, rosy-lilac, to lilac-blue and violet, with very rarely white. They vary much, too, in size.

The finest hybrid yet raised from Primula marginata is probably P. Linda Pope. It is an old plant in cultivation, though I do not know how long ago it was raised, nor what was its parentage. But it is still a rare plant, having for some time been half forgotten and more than half neglected. It is not possible to increase the stock of P. Linda Pope rapidly, and one cannot force the pace with it. It is imperturbably hardy and quite easy to grow, flourishing in any good rich loam, and flowering regularly and magnificently. But the production of side shoots cannot be hurried. It is just a case of leaving the plant alone and taking such offsets as it methodically gives, and by this means steadily doubling the numbers year by year. P. Linda Pope must therefore always remain an expensive plant. A few years ago I received P. Linda Pope under two other names. It came to me as P. Lemoinei and as P. Mrs. Hall Walker. How it came by the former name I cannot imagine, but one may suspect that the latter name may have been manufactured by some enthusiast during the brief career of the late Tulley nursery. Both varieties were tried here, and a couple of years were enough to leave no possible doubt that they were our old friend, Linda Pope, re-christened. Primula Linda Pope may best be described as a P. marginata with extra big, strong leaves, deeply and boldly toothed and notched at their edges; with a superb white margin. The very large flowers open flat and solid; they are white centred, of a most exquisite soft lavender-mauve, and as fragrant as those of P. marginata itself.

Then there is that aristocratic hybrid of marginata, P. Marven. This, too, is, I believe, an oldish garden plant, and its parents are known, viz., P. marginata × P. venusta, as indicated by its name. This is a lovely plant, though less magnificent than P. Linda Pope. The leaves are smooth edged, and smaller than Linda's, though white edged. The flowers are smaller, more the size of the funnel-shaped blooms of a normal P. marginata, but they are of a very beautiful rich blue-violet, with a central zone, which upon examination is seen to be a powdering of snowy meal. Primula Marven is of the same easy growing disposition as Linda Pope, and alas, as slow of increase and about as late.

I have recently been doing a little hybridising among P. marginata and its hybrids, and have one or two definite results already achieved, as well as a crop of promising hybrids developing. The greatest success so far is a cross between P. Linda Pope and P. pubescens Juleika Dobson, which has been christened P. Barbara Barker, after the infant daughter of Mr. Frank Barker. Primula Barbara Barker flowered for the first time in 1925, was shown at the R.H.S., and received an Award of Merit. The plant is dwarf in habit: the leaves show a little of the wavy edge of its P. marginata parentage; the flowers are very large and perfect in shape, and of a delicious soft lilac. Its other parent, P. Juleika Dobson, is another hybrid of my own raising, and has received the R.H.S. Award of Merit. The other seedling from this cross flowered last year, but did not show its true form. But it is a magnificent variety, with big, solid flowers, almost pure white. It is to be called P. Duchess of York. I have had better success with Linda Pope as a seed parent, in crossing, than I have with P. marginata, the wild type. In fact, although I have made a great many crosses on to pure P. marginata, I have not hitherto secured any seed. However, I shall try again this spring, for when she does consent to be a parent of crossed offspring, marginata seems capable of producing most lovely seedlings.

Both P. marginata and its various hybrids are excellent rock garden plants, hardy, permanent and exquisitely beautiful; they are equally valuable for growing in the alpine house, where the powdering of white meal on leaf and flower reaches its most brilliant development, and where the delicious scent may be enjoyed to the full. In the rock garden they enjoy a raised position among rocks, and a fairly sunny position. For soil they like just the rich well-drained loam that Auriculas and most other Primulas enjoy; they are in no way fussy and they like lime. *Clarence Elliott, Stevenage.*

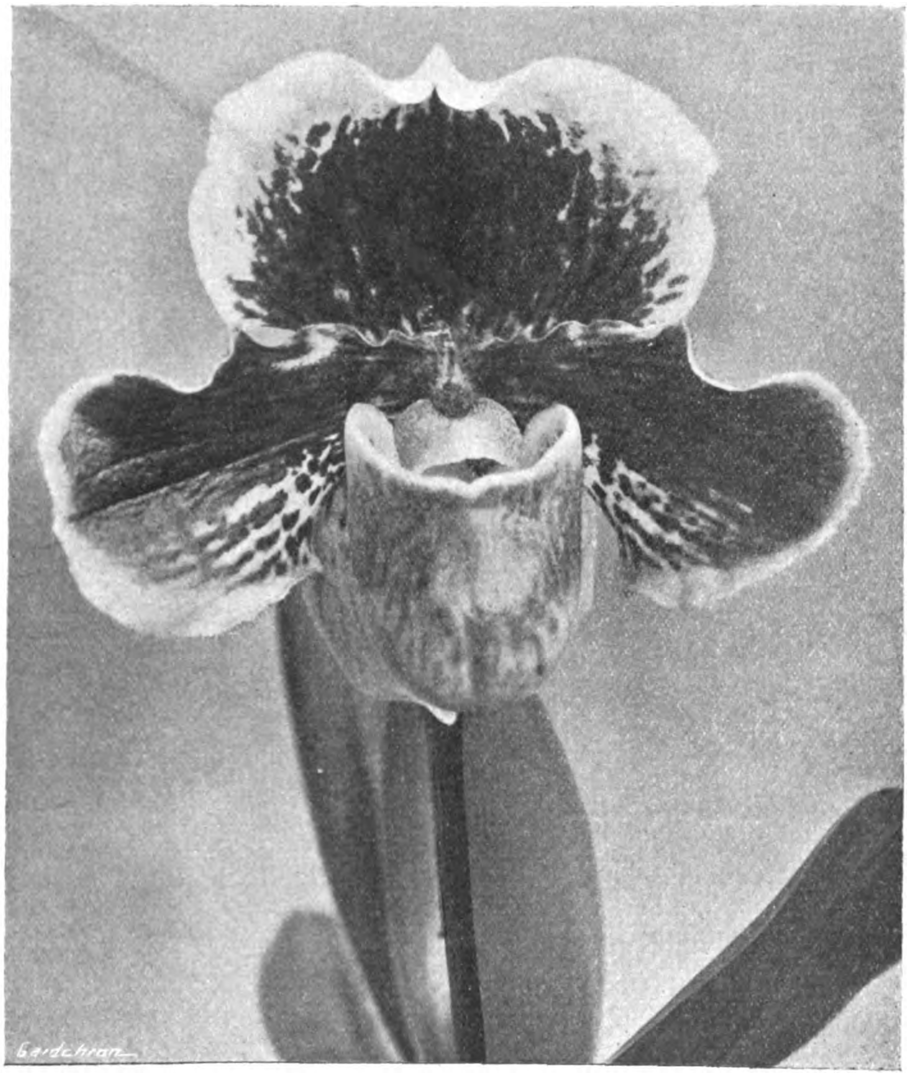

FIG. 31.—CYPRIPEDIUM MARMION, HOLFORD'S VAR.

R.H.S. First Class Certificate January 12. A handsome hybrid, remarkable for the deep wine-red colour on the dorsal sepal, and rich red-brown on the petals. Shown by Sir George Holford, Westonbirt (see p. 52).

TREES AND SHRUBS.

ZANTHORHIZA APIIFOLIA.

THIS native of the eastern States of America has peculiar purple flowers, which develop a little in advance of its pinnate "Celery-like" foliage; it forms a most interesting subject for the front of a shaded border. It is a deciduous plant with a creeping rootstock from which arise erect stems two feet or so in height, and it is from the terminal buds of these stems that the drooping panicles are produced. They consist of very numerous and minute flowers of a brownish purple shade, very neatly arranged, and of an almost feathery appearance and lightness.

A few years ago these flowers were used here with charming effect to form the tracery on the dining table, where their lightness and delicate beauty were enhanced by the snow-white linen on which they were laid.

Z. apiifolia is easily increased by division during the spring. Its creeping roots spread in all directions, but not so rapidly as to become a nuisance, and useful clumps may be lifted to form fresh plantations without disturbing the older plant very much.

As the common name of Yellow Root implies, the roots are a bright yellow colour. Although this plant was introduced so long ago as 1766, it has never become very common in gardens. *A. T. Harrison, Culzean Castle Gardens.*

GARRYA ELLIPTICA.

THIS Californian evergreen is a decorative shrub for the winter garden; its wavy-margined leaves, about the size of those of the Bay Laurel, are a deep, lustrous green, and the catkins of the male plant (the species being unisexual) are sometimes as much as a foot long, those of the female being very much smaller. These male catkins are silver-grey, beautifully tapered, and hang in a most elegant manner from the leaf-axils at the tips of the branches. They generally appear in late autumn, and in districts where the shrub grows freely, branches bearing these very ornamental tassels are used in Christmas decorations, and thus have some commercial as well as aesthetic value.

G. elliptica is indigenous to the northern part of California and Oregon, and is much hardier than many subjects from these States. It delights in the humid climate of our more westerly counties, while in many other and colder parts of the country it may be grown successfully against a wall or in sheltered woodland. Though it does not object to shade, and will often do well under deciduous trees, a sunny position is best, and it will succeed in a well-drained loam of average quality.

When it is realised that G. elliptica has been known in gardens for close on one hundred years, it is surprising that a shrub of such merit should still be comparatively uncommon. In favourable conditions it will make a well-rounded bush up to ten feet in height and as much through, and much taller specimens may be seen in the south-west.

This is one of the many Pacific Coast shrubs introduced by David Douglas, and the generic name was bestowed upon it by him in memory of his friend Nicholas Garry of the Hudson Bay Co., one of the founders of Fort Garry, now the city of Winnipeg.

RHODODENDRON GREIVEI.

SAID to be a R. ciliatum × R. glaucum hybrid, the subject of this note is one of the most delightful of dwarf Rhododendrons. To some extent it inherits a likeness to both its parents, making a low, rigid, little bush, the evergreen leaves being some two inches long and barely half as wide. These are pale green but, like those of R. glaucum, they often take on a dull golden-buff tone in winter. The pendent, bell-shaped flowers are yielded very abundantly in spring and they are of a very charming shade of delicate pink.

Though not a novelty, R. Grievei is seldom seen, and apparently it is still rare. This seems odd for it is a very beautiful little shrub, hardy, and easy to grow in any soil that suits Rhododendrons. It flourishes with me in a cool bed of well-drained loam in the part shade of woodland, some old leaf-mould only being given at the time of planting.

RHODODENDRON WILSONII.

OF the several useful Rhododendron hybrids for which we are indebted to the North American R. punctatum, R. Wilsonii is perhaps the most charming. Its longer, narrower and more pointed leaves in a soft olive-green, and the less rigid and much more graceful habit of growth seem to me to afford it a distinction and beauty not shared by R. arbutifolium or R. myrtifolium. Its pale rose flowers, borne in good sized trusses are also rather larger than those of the other two hybrids mentioned, each bloom being about one-and-a-quarter inch across.

Being very adaptable, R. Wilsonii may be grown on the bolder parts of large rock gardens, grouped among other dwarfs, or alone in the open woodland or Heath garden. I have several specimens among Heathers in ground that gets exceedingly dry in summer, yet they hold their own with their companions, flower profusely, grow rather slowly (which is an advantage under the circumstances) and never suffer from drought. As R. Wilsonii is usually on its own roots, it possesses a great advantage over many others when the planting is done, as I have suggested, where supervision in regard to suckering would prove irksome and out of place. *A. T. Johnson.*

AMERICAN NOTES.

CARNATIONS OF MERIT.

ONLY a few really good Carnations are being introduced in the United States this season as raisers are becoming yearly more discriminating and hesitate to put on the market anything which does not seem to be at least the equal of standard varieties. Nothing on the list is the superior of Laddie as a salmon-pink and Spectrum as a red; these two varieties are both well-known on your side, and were raised by the well-known Dorner firm of Lafayette, Indiana; they command a higher price in the flower markets here than any others. Whether Spectrum will stand the test very long, is, I think, doubtful; it is rather lacking in stem and red is not a very saleable colour here except at certain holidays.

William Sim, of Cliftondale, Mass. (who is a Scotsman, by the way) is the largest grower of Carnations in the east, and has raised some excellent seedlings; one, named Royal, is of a pleasing royal purple colour; another, Arctic, has large, pure white, very fragrant and splendid-keeping flowers; these sorts are now being introduced. Mr. Sim has quite a number of other good seedlings, some of which are of orange, apricot and other rather unusual colours. The American retailers seem to be "glued" to a few shades of colour like white, dark, medium and light pink, and in a much reduced way, yellow, red and variegated; they rarely offer anything outside these shades, and rather give Carnations the cold shoulder in favour of Roses.

C. B. Johnson, of Woburn, Mass., is another very successful raiser of seedlings; his Johnson's Crimson is probably the finest of its colour to date. A very fine white sort, awarded a silver medal in Boston, is Ivory. The same grower has some excellent pink, scarlet and variegated seedlings to come. Red Laddie is known in England, but is not sufficiently bright to be very taking. We have virtually no yellow but Maine Sunshine here; I thought that Saffron, as I saw it in England last summer, better. Betty Lou, as a pink, seems to be doing well with many.

The annual convention and exhibition of the American Carnation Society will be held in the Horticultural Hall, Boston, on January 28 and 29; this, it is believed, will set a new high record for American Carnation exhibitions, both in numbers of flowers, quality and artistic arrangement. In the past, particular growers here have been very backward, usually putting fifty or one hundred blooms in large wide-mouthed receptacles, with no effort at arrangement. Staged in this way the commercial growers have felt that they could study the blooms better and decide how many hundreds or thousands they would buy for the coming season. The Carnation, however, is far less popular here as a cut flower than the Rose, and growers are beginning to appreciate the fact that the great amateur, buying public are not impressed by these inartistic displays.

I had the pleasure, while in Great Britain last summer, of seeing some of the large Carnation establishments, including those of Mr. W. E. Wallace, Mr. C. Engelmann (almost as well-known here as on your side), Messrs. Lowe and Shawyer, and Messrs. Allwood Bros., and was agreeably surprised to see the high quality of their stocks; as seen in August, the flowers were nearly equal to what we get here in mid-winter, and I have no hesitation in stating that your best growers are somewhat ahead of ours in America, and they certainly pack flowers for market much more carefully than we do. Your growers pack all the best flowers in single layers; here the flowers are tied in round bunches of twenty-five each, and are subjected to much rough handling. I think our growers may be able to teach you some things, but when it comes to marketing their flowers they are very far behind British growers. Carnations do not appear in our markets all the year round, as with you; there are none in July, August or September, while in June and October they are very small and short-stemmed, and practically for half the year they are either not to be had at all or of indifferent quality.

NEW AMERICAN ROSES.

One or two really fine new hybrid Tea Roses are being sent out this winter. Briarcliffe, which originated with Paul Pierson, Briarcliffe, New York, is a glorified Columbia, of brighter colour and not throwing the so-called "bull head" flowers so characteristic of Columbia. It has won very high encomiums from all who have seen it exhibited or growing. Another variety from the F. R. Pierson Co. is Mr F. R. Pierson, a red, something in the way of the well-known American Beauty (Mme. Ferdinand Jamain), now fast passing out as a forcing Rose. Roselandia, the new orange-yellow from your side, is being made much of as a forcing Rose.

The dominant forcing red Rose to-day in the U.S.A. is Templar, raised by the Montgomery Co., Hadley, Mass., and sent out a year ago. I saw a big house of this at Hadley in November, with 60,000 flowers coming on, the great proportion of which would come in for Christmas. Many of these blooms would be cut with three feet to four feet stems. This noted firm, which has given us so many fine forcing Roses, had 10,000 seedlings under glass, raised from seeds the previous January, and containing some beautiful varieties; one was similar to Mme. Alexander Dreux in colour, but much fuller; others resembled Souv. de Claudius Pernet, which holds high rank here both as a forcer and as a garden Rose; still others appeared to be pinks, the superior of Columbia; and there were some glorious reds. This firm is very discriminating and never introduces anything which has not had an extended trial and proved to be ahead of existing varieties. Red Premier is well thought of here; it is really not red coloured but a very deep pink and blooms with remarkable freedom.

I believe mid-winter Roses are not produced much in England on account of your lack of winter sunshine, but allowing for that, I have an idea that if your growers would build large wide, light houses, such as we have here, and would use steam heat as Mr. Engelmann is now doing at Saffron Walden, you could produce just as good flowers as we do. You have shown that you can do it with Carnations, you can beat us with Chrysanthemums, and I look to see British Rose growers (under glass) giving American specialists a close run in the very near future. *William N. Craig, Weymouth, Mass., U.S.A.*

INDOOR PLANTS.

SWEET-SCENTED WINTER-FLOWERING PLANTS.

There are numbers of sweetly-scented plants that flower during the winter and early spring. Considering that perfume in plants and flowers is always appreciated, it is surprising how seldom the plants under consideration are seen in gardens at the present day. Most of them are quite easy of cultivation.

Mitrostigma axillare (syn. Gardenia) is, at the time of writing (early January), well in flower. It is a native of Natal and succeeds quite well in an intermediate or warm greenhouse. When planted out in a well-drained bed or border it makes a neat evergreen bush, some four or five feet tall. Cuttings of this plant root readily in a propagating case; they should be made from leading shoots, for although lateral growths root quite readily, such plants never form a leading shoot, but retain their lateral character. Young plants are best grown in a temperature of about 60°, but when in flower they may be placed in a warm greenhouse; they produce their white, sweetly-scented flowers during winter or early spring and excellent specimens for the stage may be grown in six-inch pots. The plant grows freely in a fairly light compost.

Acokanthera spectabilis (syn. Toxicophlaea spectabilis). This plant, commonly known as the Winter Sweet, is a native of Central and South Africa, and like the Mitrostigma is evergreen, succeeding when planted out in a stove or intermediate house. It is much larger, but may easily be kept within bounds by pruning; fine specimens may be grown in large pots or tubs, or in small pots for furnishing the stages in the intermediate or warm greenhouse.

Cuttings root readily in a warm propagating case furnished with bottom heat. The young plants should be grown on in a house having a temperature of about 60°. Any kind of good potting compost is suited to this plant. The white, sweetly-scented flowers are produced freely during winter and early spring, the period varying according to the temperature of the house in which the plant is grown. A. venenata is another South African species.

Daphne odora (syn. indica) is a better-known plant and a great favourite owing to its deliciously scented flowers, but it is seldom seen in good condition as it is by no means an easy plant to keep in good health for any considerable length of time in pots. Large specimens are by no means uncommon out-of-doors, growing against warm walls in Devon and Cornwall; even there it is usual to give the plants the protection of a mat during frosty weather. This plant is not happy under pot cultivation, and should be planted out in a well-drained bed or border in a cool greenhouse. Specimens in small pots are useful for the stages, and such plants are grown in limited quantities by a few growers for market. The Sweet Daphne is generally regarded as being difficult to propagate, and it was the practice of former growers to graft it on stocks of some of the hardy species. It is, however, not difficult to propagate if half-ripened shoots are secured from plants growing indoors. The cuttings are best inserted singly in small pots, standing them under a bell glass in a greenhouse, or in a case provided with slight bottom heat. This Daphne succeeds best in a compost of good, medium loam, with the addition of a little fibrous peat and sand. Efficient drainage and careful watering are necessary at all stages of growth.

Luculia gratissima, a native of the Himalayas, produces large trusses of beautiful pink, deliciously scented flowers in winter. It is one of the most beautiful of cool greenhouse plants, but it is by no means common. It is difficult of propagation, although from time to time a few trade establishments have enjoyed the reputation of propagating it readily and in quantity. Occasionally one sees it stated that this plant is easily propagated by means of cuttings, a statement which deceives no one who has any experience with it. Cuttings are best secured from the smaller, twiggy shoots that are produced after the plant has been cut back. They should be inserted singly in small pots filled with sandy soil, and plunged in a case furnished with bottom heat. The leaves should on no account be allowed to flag, and it seems to make a difference if the leaves are kept upright by tying them to a stake. This is one of the plants that seem impossible to be grown successfully for any length of time in pots; it should, therefore, be planted out in a well-drained bed in a cool greenhouse, where, if it lives long enough, it may attain to a height of twelve feet.

After flowering, towards the end of January, the plant should be pruned and kept on the dry side at the roots until it starts into growth again. It is somewhat subject to attacks of mealy bug, white fly and Begonia mite, all of which must be guarded against. Sometimes lateral growths may start below the inflorescence; if these develop before flowering they should be rubbed off. In the neighbourhood of London, fogs often ruin the flowers.

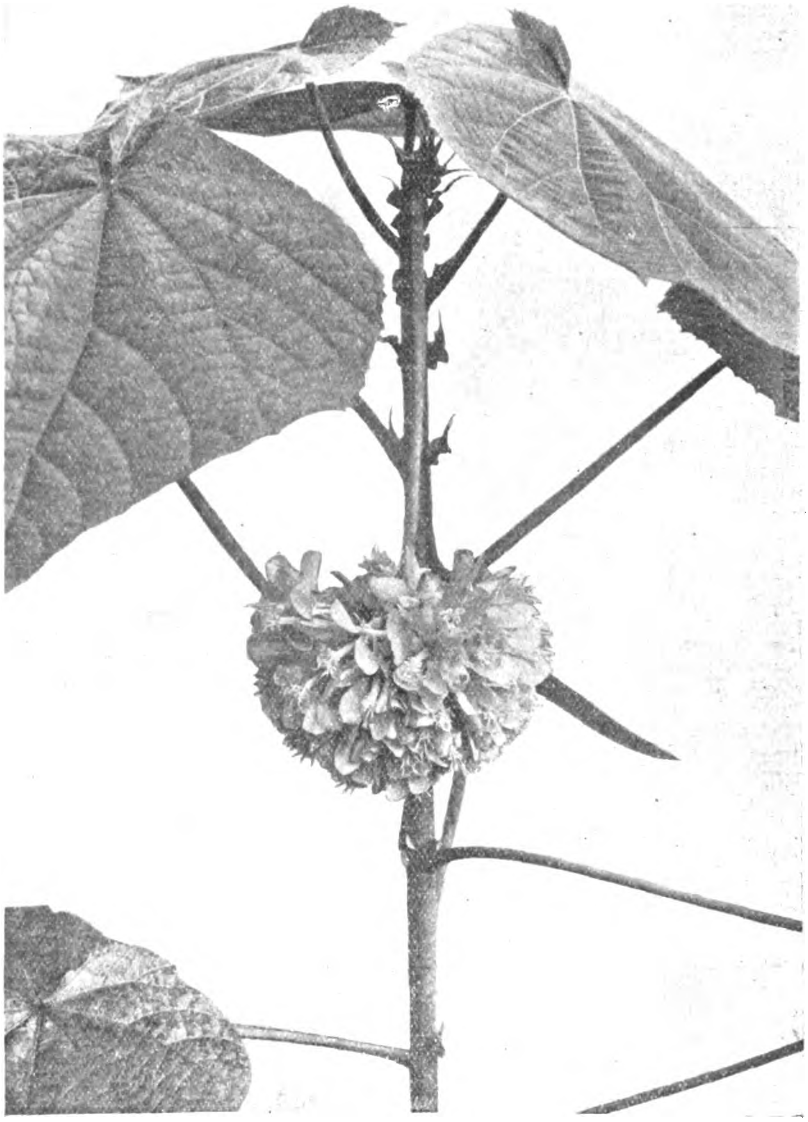

FIG. 32.—DOMBEYA SP. (D. GLANELIAE ?).

R.H.S. Award of Merit, January 12. A robust, warm-house shrub, with large, handsome leaves and round, pendant clusters of bright, pink flowers. Shown by Lord Glanely, Chippenham.

(see p. 53).

Buddleia asiatica (syn. B. Neemda), a native of the East Indies, is an old garden plant introduced so long ago as 1894, and is still uncommonly scarce in gardens. Its long, slender sprays of small white flowers are most delicately scented.

B. officinalis is a more recent introduction from Western China, whence it was introduced by Mr. E. W. Wilson in 1908. It has lilac-coloured flowers with yellow centres, the strong honey scent of which appeals to some individuals. This Buddleia makes a stiff, bushy plant which, however, lacks the grace of the older species.

B. asiatica is propagated by means of cuttings in a close case with slight bottom heat. Twiggy shoots should be selected for this purpose, as the stronger shoots are liable to damp off. Plants rooted during March, if stopped twice during the growing season, will make bushy specimens for the plant stage their first season, but they are seen at their best the second year. When the one-year-old plants have flowered they should be shortened and potted on as they require it into eight-inch or ten-inch pots. Well-grown specimens attain a height of five feet to ten feet. The ends of the shoots and laterals terminate in long sprays of fragrant flowers. During the summer the plants are best plunged out-of-doors in an open, sunny situation.

B. officinalis succeeds under the same treatment but is a much easier plant to propagate and cultivate. Both species grow freely in any good potting compost.

Eucharis and Gardenias may be had in flower during the winter and spring, but they are not cultivated to the same extent as formerly. Other sweetly-scented winter- and spring-flowering plants are Roman and other Hyacinths, Paper-white Narcissus and other Tazetta varieties; Jonquils, Freesias and Lily-of-the-Valley, all so well-known that they need only be mentioned. *J. Coutts.*

LILIES IN 1925.

THOUGH the year began and ended in inauspicious fashion, the Lily season of 1925 in the south of England only just failed to be a great one. The failure—such as it was—to reach perfection, and the success of the season were both due to the peculiar character of our climate.

It has often been said that Lilies are children of the sun, and the truth of that trite observation was never more clearly demonstrated than in the year which has just brought the first quarter of the century to a close.

Except that the northerly and easterly winds had not quite that rasping quality which made the early months of 1924 almost unbearable, the weather of the first quarter of last year was very much the same as that of its predecessor. There were odd days in each of the first four months during which our island was dominated by continental winds, when the birds—always the first to discover and announce such days—sang from the depths of their hearts; but in the main, it was a shrivelling time in the south. So shrivelling, indeed, that May Day found plant life unusually backward and Lilies so belated that not one of the Californian species was above ground. To those with intimate experience of the genus in the garden, and always on the *qui vive* for the first sign of the plants above ground, such exceptionally tardy growth seemed ominous; but so little do we know of Nature's ways, so slow are we to learn, that what then seemed of ill augury was really only Nature's way of preparing a *coup*. She continued her preparations in such leisurely fashion that even a brief burst of summer in the middle of May found those same Californian Lilies still below ground, and it was not till the end of the month that the first green "points" of L. Parryi, L. pardalinum and the rest, and the bronze points of L. Humboldtii magnificum ended a period of suspense which only keen cultivators of plants can appreciate.

Looking back over the period and remembering how thirsty Lilies are when in growth, it seems possible that the lack of rain in May may have had as much to do with the slow growth of some Lilies as the chilly winds and generally cheerless weather; but that it did not affect them all in the same way was evident from the fact that the European Lilies—always less at the mercy of our climate than those from North America and Asia—kept to the clock. In nine years out of ten, L. pyrenaicum comes into bloom in the Home Counties during the first week of June, and as a rule it is the first Lily to flower. In 1925 it changed places for the nonce with L. pomponium, and both were in flower while the Californian Lilies already referred to were only an inch or two above ground.

The first half of June brought real summer, but no rain; nor was there any during the second half, which was characterised by dull weather, overcast skies, cool, northerly winds and so meagre an allowance of sunshine that the average day temperature was nearer 50° than 60°F. Technically, the drought was broken in the south by a drizzle on Midsummer Day, but in many places it was hardly enough to lay the dust.

The hot weather for which the heart of last summer will be remembered began in earnest on June 29, with a change in the wind from north-east to south-east, and it held till July 26, when, after a widespread series of thunderstorms, the torrid heat and drought ended simultaneously. In this country we are accustomed to sudden and violent changes in the weather, but assuredly the most experienced gardener would be put to it to remember a change like that of July 26 and 27 last, when the day temperature, which for some time had been in the eighties, fell in a few hours to 55°F. Once gone, the hot weather never returned, and except for an odd day now and again, August was a cheerless month; September was worse, for in the first week of the month a cold snap brought heavy snow to Scotland and a brief, destructive frost to the south. October, on the other hand, lingers gratefully in the memory, for the first half was unusually sunny and warm. It completed the roasting and ripening of bulbs and wood begun by the heat of July, and no doubt laid the foundation of what we may hope will be a wonderful display a few months hence.

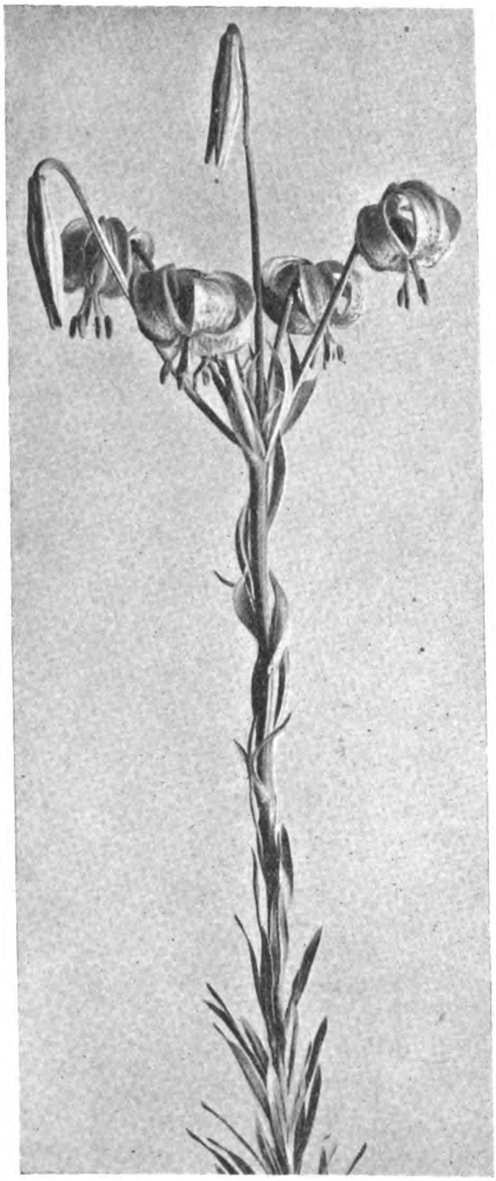

FIG. 33.—LILIUM CHALCEDONICUM VAR. MACULATUM IN MR. FRANK JONES'S GARDEN AT LECHLADE, 1925.

The roasting heat of July had an exhilarating effect on all Lilies, except L. candidum, which by then was so deep in the clutches of Botrytis as to be beyond recall. On all sides the ravages of this disfiguring disease were only too apparent, and nowhere was the tragedy more noticeable than in the famous semi-circular bed of the Madonna Lily between the Palm House and Greenhouse at Kew. It will be a red letter day for horticulture when science finds a prophylactic and a cure for this most foul disease, which makes astonishing headway in such cheerless weather as prevailed throughout the late spring of 1925. For a few years after its introduction, it seemed as if the wild form of L. candidum from Salonica might be more resistant to Botrytis than the garden forms, but the experience of last year seems to show that it enjoys no immunity.

Many other species were attacked by the fungus, but few fall victims so readily as L. candidum, and in the case of the other Lilies the sun made such short work of the mischief that cripples were few and far between. Except L. candidum, all the early and mid-season Lilies outdid themselves, and though the rains of early August, falling on a baked and parched earth, put new life into the late-flowering group, the weather of August and September was against them, so that, on the whole, they made no more than an average display. L. Sargentiae needs a hot August and found the chilly weather too much for it. L. Willmottiae, which flourishes in shade and is not so dependent on the moods of the sun, was hardly so floriferous as usual. L. pardalinum, on the other hand, has seldom been so good, and the same may be said of L. chalcedonicum which found the heat of July so much to its liking that quantities of the blooms were to be seen on sale in Covent Garden market—a very rare event. After an absence of some years, the variety maculatum is coming into cultivation again, and is proving a formidable rival to the type plant. It has rather more stature and may be of more robust constitution. The illustration in Fig. 33 shows the three "spurs" so characteristic of the heads of this variety and the type.

Where L. auratum was sheltered from the chilly winds it flowered well last autumn, but browned, withered and malformed petals too often caught the expert eye. L. tigrinum was better than most, and though obviously ill at ease in the coldest early autumn of recent years, L. philippinense var. formosanum made a brave show. The tall-growing form of this Lily, which we owe to E. H. Wilson, who found it in Formosa, did well last year; so tardy a plant is naturally the sport of a cold autumn, but the warm, sunny days of early October coincided with the flowering of this most elegant Lily and brought out its many good points.

Of the early-flowering group of Lilies, L. concolor was more at home in the torrid heat of July than it has been since 1921; it flowered well, and ripened a quantity of seeds, and the bulbs were so well roasted that if the coming summer is propitious, a good flowering is assured. This Lily, which is all too seldom grown in England, furnished a good example of the effect of the sun on the life of flowers. The blooms of a group of the species in semi-shade lasted for twenty-two days, while only eleven days elapsed from the opening of the buds to the falling of the petals in another colony, fully exposed to the sun.

In early June, L. pomponium was unusually floriferous, and the well-balanced head shown in the photograph (Fig. 34) was by no means unique. This plant of the Maritime Alps varies a good deal in size of flower, stature and foliage, and the differences do not seem to depend altogether on cultivation. It is customary to refer to the Lily illustrated in Fig. 34 as Lilium pomponium verum, but it is probably nothing more than a robust form of the wild plant, and is not to be confused with Maw's plant, which is probably not in cultivation now.

Though it grows well under glass, L. neilgherrense (Fig. 35) has never taken kindly to outdoor cultivation in England. It might be supposed that this turns on temperature more than anything else, but our wet winters are quite as likely to be responsible for failures with the plant. Mrs. Wigram Money writes that in their native hills these Lilies endure drought and severe frosts from November to March, but thence onwards to August or September are in almost swampy ground, with a temperature seldom exceeding 63°. It is the sodden state of the ground in our winters which makes the management of many exotic Lilies so troublesome.

On the whole, the harvest of Lily seeds was not bountiful, though a great deal better than in 1924, when both the crop and the subsequent germination were as poor as could be. As an instance, seeds of the 1924 harvest of L. regale, sown in the open in January and February, 1925, did not germinate at all, though seeds of this species usually germinate like Mustard and Cress. The same poor germination was noticeable, too, in vegetable seeds.

The year was not remarkable for the introduction of any new species of Lily, but will be remembered for the publication of Mr. E. H. Wilson's *The Lilies of Eastern Asia*—a monograph worthy of its author. Among minor features of interest in 1925 was the sale of flowering stems of L. speciosum at a few pence each by hawkers in the London streets on Michaelmas Day, and a wonderful exhibit of L. Duchartrei var. Farreri by Col. Messel at Vincent Square on July 14.

The comparatively hard weather of the first two months of the present winter will have done Lilies nothing but good because it will have kept the ground drier than it usually is in the opening stages of winter. The torrential rains of the post-Christmas fortnight are another matter, but they also will have done little harm because established bulbs of Lilies are "pointing" below ground by then, and even those planted in October will have taken root. Once the basal roots are active, Lily bulbs may be drowned for a time without hurt. But it will have gone hard with the bulbs of newly-imported Japanese Lilies which were planted in thousands before Christmas by innocent folk. *A. Grove.*

CLASSICAL AND LEGENDARY GARDENS.

I.—THE GARDEN OF THE HESPERIDES.

MAN'S age of gold is usually behind him. To this fact allusion is made by Milton in his delightful Ode :—

> For if such holy song
> Enwrap our fancy long,
> Time will run back and fetch the age of gold.

It were a pity to live always in the past ; and it is pleasing to find that while the Hebrew Scriptures open with a vision of Paradise, those of the New Testament are brought to a close with the promise of a better. We may still look for a golden age and a Paradise Restored. Among the many Edens with which ancient literature makes us acquainted there is probably none outside that of the Book of Genesis which is more familiar than the Garden of the Hesperides. We therefore place it in the forefront of our review of Gardens of Romance and History.

A moment's thought reveals a fact that is noteworthy. We think of gardens as late productions, the work of races far advanced in civilisation, and we usually associate them with toil and the sweat of the brow. But already in the very dawn of literature the garden finds a place ; and so far from being a field of labour, tilled by unwilling hands under the lash of a cruel task-master, the garden is a place of pleasure and delight. It is the abode of love, the retreat of Adonis or Venus, where flowers bloom and golden Apples grow. But since there is ever a serpent where there is an Eden, the early garden soon becomes the stage of passion. Where love is, and Apples of gold, there will soon be jealousy and envy. The fruits will prove to be Apples of discord. Rivalry comes into play, with consequent defeat and triumph, and so the gardens of the poets show themselves to be very real ; the true playgrounds of life as it ever was, is, and ever will be. Under the poetry and legend we find the deepest truth, and for this reason the old authors are worthy of our devoutest thought.

It is interesting to observe that the legendary garden was not in the East. Note the instructive words—Hesperides, Hesperus, Vespers, Eventide, the Sunset, the West ! Why not England ? Had the early Greeks some notion that, at the spot where the sun went down to his couch in splendour, there lay an island which was fit to be the abode of the gods ? What harm, if we fancy for the time that the garden was here ? For us this is more flattering than Madeira or the Canary Islands, where some would locate it.

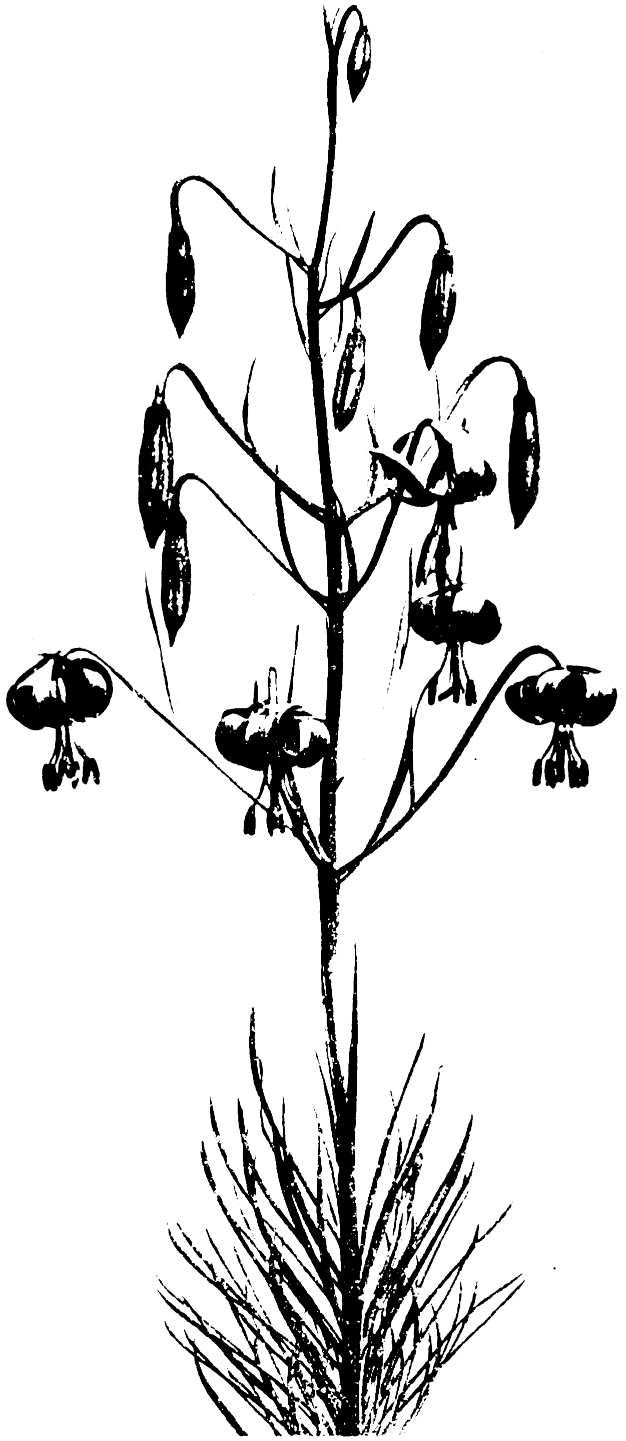

FIG. 34.—LILIUM POMPONIUM IN DR. AMSLER'S GARDEN AT ETON, 1925.

The earliest forms of the legend represent the nymphs known as the Hesperides as living on the Oceanus in the extreme west ; and, if our geography be correct, there is nothing further west than ourselves. According to Hesiod, moreover, these gardens were in an island of the western seas, and not on the continent. The Hesperides were the guardians of the golden fruits which this island garden grew, and they were aided in their work by Ladon, the Dragon. How true to life ! The Picts call in the Scots to assist them. It is the old, old story, illustrations of which are to be found in the historical archives of every land. And it is the task of Hercules to gain possession of the coveted fruits. The best things of life are only for the giants of the race. Best fruits are ever out of the reach of the child; best places can only be secured by prowess or daring, craft or cunning. This is no fable, though it passes by that name. The serpent in Eden, the dragon in the garden, Hercules needed to pluck the fruit—it is all true to life.

Mythologists have differed in their interpretation. Some years ago the school of the Solar Myth held the field. According to them (and here they were right) a garden implied a gardener. Genesis makes the Lord God the planter and Adam the keeper. The mythologists say, "the celestial gardener is at one time the moon, at another the sun, often represented as a dragon. The gardens of the Greeks and Romans were under the high protection of Hercules, perhaps because of the exceptional rôle played by him in the legend of the famous garden of the Hesperides which was placed in the region where the sun sinks to rest." That mode of interpretation has had its day, and now the historian and the master of commerce are trying their hands at an explanation. It is becoming more and more evident, as old records are unearthed, that from incredibly early times West and East were in constant communication. Egypt traded with Assyria, the Phoenicians abolished distance, the Etruscans made roads which served as a model for Rome, and it needed few links to forge a chain of commerce between the Cassiterides in the west and Cathay in the east.

There are bold spirits, therefore, to-day who affirm that in these so-called legends we are to find the beginnings of the history of world-wide commerce. This, of course, is courting the anger of the gods; yet, already in the days before Caesar and Cicero, I find Lucretius (born about a century before Christ) throwing out his challenge in these famous words: "And the serpent which guards the bright golden Apples of the Hesperides, fierce, dangerous of aspect, girding the tree's stem with his enormous body, what harm, pray, could he do us beside the Atlantic shore and melancholy main, which none of us goes near, and no barbarian ventures nigh? And all other monsters of the kind which have been destroyed, if they had not been vanquished, what harm could they do, I ask, if now alive? Methinks none." There is the true scientific spirit which is ever opposed to superstition and fear.

It was at one time the fashion to look on all these legends as perversions of the truth which was to be found solely in the Hebrew Scriptures. Such theories, now fortunately as antiquated as the Solar Myth, found expression in such fictions as the following: "The words Aitz-Peri mean a fruit tree (Genesis iii., 11), and from these two Hebrew words the famous gardens of the Hesperides (!) seem to have had their name. And from what passed in Paradise, concerning the fruit of the tree (Genesis iii., 3) between the serpent, the woman and the man, and from the promise that the woman's seed should bruise the serpent's head, the heathen appear to have derived those distorted traditionary stories of Hercules carrying off the golden Apples of the Hesperides, though guarded by a tremendous serpent or dragon whom he vanquished; and of the Massylian priestess in the temple of the Hesperides, who fed the dragon and preserved on the tree the sacred boughs. In Spence's *Polymetis* (Pl. XVIII, Fig. 8), we may behold Hercules, as represented in an antique, standing with an Apple in his hand before the tree, and the serpent twisted round it."

Ancient history and mythology are so intermixed that it is often difficult to separate the one from the other. Careful and well-informed students are able, however, very frequently to show the relationship between them. Thus a very able historian, commenting on a legend which is to be found in *Herodotus* (Book ii, ch. 55) tells us that in early ages commercial intercourse existed between India and Arabia, Ethiopia, Libya and Egypt. This was based on their mutual necessities and became the parent of their various civilisations. He adds that traces of this "are found in the earliest Greek mythology, in the fame of the Ethiopians and the hundred-gated Thebes, the myths of Jupiter, the Triton Sea, and the Garden of the Hesperides." The Greeks seem to have applied the term Hesperus to Italy, but the Romans do not appear to have accepted the designation. In the *Odes* of Horace it is also used of the neighbouring peninsula. Writing of Spain and Portugal, one author remarks that: "Numerous fertile valleys slope down to the shore where the rivers revive the vegetation. The stately Chestnut trees congregate in forest, and the cork and evergreen Oaks yield their bark and galls, as well as sweet mast, which is ground into meal, and like the Chestnut used for bread. Orange groves perfume the air with their flowers; and the golden fruit hanging at the same time from the boughs recalls the fabled garden of the Hesperides."

But what were the golden Apples which the dragon guarded and Hercules sought to obtain? That no one can tell. The word Apple is synonymous with fruit in general, but it may be taken to mean any desirable thing. If it be said that here the Orange must be intended, then history, philology, the origin and distribution of cultivated plants and fruits, with a score of other questions would need to be considered. One of the difficulties with which Hercules had to contend was ignorance of the locality, and that difficulty remains unsolved. He applied to the Nymphs to learn where the garden was to be found. Some writers think the Apples were the symbol of love and fruitfulness. I prefer to find here an illustration of the old-time method of writing history. Adventurers had sallied forth into unknown parts and brought back their travellers' tales, and these were duly handed down to posterity by oral means. Eventually they were committed to writing, but during the long traditional period names had undergone various changes, and statements were modified to fit in with the advance of knowledge, until eventually the old meaning was lost, and history became legend and myth.

We might re-write the story in some such fashion as this. Away in the west, where the sun sinks to rest, is a land where many precious things are found. To reach that land or island many dangers have to be met. The Gulf of Lyons is perilous to the mariner. The Bay of Biscay is seldom calm, and it is a Herculean task to reach those distant shores. Even when the voyage has been safely negotiated the natives have to be humoured. They will not give up their treasures—rich metals, precious woods, luscious fruits, beautiful women, fair-headed children—which are guarded jealously, save at great cost. Commerce is an enterprise reserved for the most daring souls, and all honour to the men who undertake such enterprises for their country's good. *Hilderic Friend.*

FORESTRY.

The Influence of Prolonged Daylight in the Vegetative Season on the Quality of Coniferous Timber Grown at High Latitudes.

(*Continued from p.* 49).

From the table published on p. 49 we have seen what are the relative values at the spring equinox in the northern hemisphere of the chemical intensities of the direct sunlight and of that reflected from the sky at the terrestrial latitudes mentioned. From this we may obtain some idea of the changes which take place in the intensity values at these latitudes as the earth moves in its path from the spring equinox to the summer solstice, and thence to the autumn equinox.

Before discussing this, however, reference may be made to another aspect of the matter which has a marked bearing on plant growth at the higher latitudes, namely, the relative amounts of sun heat received by a hemisphere of the earth in the summer and winter halves of the year respectively. It has been shown by the late Sir Robert Ball, contrary to an assumption based on an erroneous statement by Sir John Herschel that the summer and winter amounts were equal, that "of the total amount of heat received from the sun on a hemisphere of the earth in the course of a year, sixty-three per cent. is received during the summer and thirty-seven per cent. during the winter."* But these proportions apply, of course, to a hemisphere as a whole, and they give no indication of the way in which this excess of heat in the summer season is distributed over it at the various latitudes, or of its relationship to vegetation at these latitudes. In the vicinity of the equator the amounts received in summer and winter are about equal, and there plants receive their annual supply of light and heat in daily instalments of approximately twelve hours each all the year round, as would be the case all over the globe were the earth's axis perpendicular to the plane of the ecliptic. But, owing to the obliquity of its axis, at the poles the whole of the light and heat which reaches the earth at these parts is received in the summer half of the year. As we proceed from the pole to the equator the inequality lessens, the summer amount of sunlight decreasing and the winter amount increasing, until, when the tropics are reached, the seasonal distinctions practically disappear, and in the tropical zone the summer and winter proportions become approximately equal in duration.

It will thus be seen that, although the proportions of light and heat received by a hemisphere as a whole in the summer and winter halves of the year respectively are, as Sir Robert Ball has stated, sixty-three and thirty-seven per cent., the relative proportions received in summer and winter vary greatly from latitude to latitude. For example, at Assouan, Egypt, at the northern tropic (23½° N.), which is the farthest north latitude at which the sun is directly overhead in the northern summer, the difference between the longest and the shortest day of the year does not amount to quite three hours; at Oslo, Stockholm, and Leningrad, all of which are approximately on the 60th parallel of latitude, the difference is not less than thirteen hours, and for months there is no real night there, while at the pole the sun does not disappear beneath the horizon for six months annually. At the equinox, at these high latitudes the intensity of the sun's rays, on account of their obliquity, and the greater depth of atmosphere which they have to penetrate is, for equal periods of time, as we have seen from the table, much less than within the tropics, or even at less low latitudes. But, as Warming points out, "the development of plants depends not only upon the intensity but also upon the duration of the light to which they are exposed."†

At high latitudes, as contrasted with low latitudes, the day lengthens rapidly after the spring equinox, and the rate at which it lengthens accelerates as we approach nearer and nearer to the poles. For example, at the latitude of London (51½° N.) on April 21 the day is longer than it was at the equinox by fully 2 hours, on May 21 by about 3 hours, and on June 21 by about 4½ hours; and at the latitude of Edinburgh (56° N.) the lengthening for the corresponding dates is approximately 2½, 4½, and 5½ hours respectively. At the latitude of Leningrad (60° N.) on April 21 the day has lengthened by about 3 hours, on May 21 by fully 5 hours, and on June 21 by about 6½ hours. At Tornea, at the head of the Gulf of Bothnia (66½° N.), on April 21 it has lengthened by 4 hours, on May 21 by 7½ hours, and on June 21 the sun has become a circumpolar star; and at Altengaard, in Finmark (70° N.), which is about the northern limit of tree growth in Norway, the sun is a circumpolar star from March 21 to July 22, making sixty revolutions above the horizon in that time, so that the longest "day" there corresponds to a period of two months, and the longest night has, of course, a correspondingly long duration. The higher the latitude, the more rapid, of course, is the transition from winter to summer, and the effect of this rapid increase in the length of the daylight, and consequently in the temperature of the soil, after the vernal equinox is reached at these high latitudes, as compared with lower latitudes, is well exemplified in the case of annual crops.

---

* *Cause of an Ice Age*, p. 90.

† *Ecology*, p. 17.

In Finland, all of which lies to the north of the 60th parallel of latitude, and the north of Norway, according to Warming, "Barley ripens its grain in eighty-nine days from the day of sowing, but in Schonen (in Sweden, 55°-57° N.) it requires one hundred days, despite the higher temperature and the more intense light; and the explanation of this must, in part, be that in the former places prolonged illumination promotes anabolism. In the north the periodic vital phenomena of plants set in much more rapidly in summer than in spring, because of the longer duration of the daylight. Arnell states that, going northward from Schonen, for each degree of latitude anthesis is later by 4·3 days in April, 2·3 days in May, 1·5 days in June, and 0·5 of a day in July."* Warming also states that "in Polar countries light is less intense and temperature lower, but their action or growth is subject to less intermission; the distinction between the temperature by day and by night becomes obscured. Intense light by day and cold by night co-operate at high altitudes in retarding growth; prolonged, though weaker, light and lower temperature in Polar lands have the same effect."† And, referring to the yearly periodicity of growth, Pfeffer states that "when prolonged periods of cold delay the renewal of vegetative activity, favourable conditions produce a more rapid response than if they were applied earlier. In this way arises the sudden outburst of foliage when a cold spring is succeeded by warm days at the end of April or in May."‡ At high latitudes this phenomenon is of annual occurrence on a grand scale, because, for a considerable time after the vernal equinox the larger proportion of the sun's heat is being used up in melting the vast masses of snow and ice which have accumulated in the winter season, and it is only after this has been accomplished that there can be any marked increase in the temperature of the soil and air, hence the rapid outburst of growth which immediately follows its disappearance.

The great forest region of Northern Russia, the largest expanse of uninterrupted Coniferous forest land in Europe, lies mostly above the 60th parallel of latitude, stretching almost to the arctic circle, and, owing to the much greater length of the day, coupled with the fact that there is no real night, in the growing season plant life there enjoys an immensely longer duration of daylight than it does in the lower latitudes of the north temperate zone. In the growing season there the rainfall is light, but the accumulation of snow (in which form by far the greater proportion of the moisture precipitated from the atmosphere occurs) in the long winter furnishes, when it melts under the influence of the summer sun, a sufficient supply of water for the use of the plants. In the past these Coniferous forests have been naturally regenerated, and there has been no tending of them. They have, no doubt, been ruthlessly exploited, and in the more accessible parts probably the best of the timber has disappeared; but in the interior of this great region, far from the exporting centres, there must still exist enormous tracts of fine forest of this sort. *A. D. Richardson.*

NOTICES OF BOOKS.

Insecticides, Fungicides and Weed Killers.*

THIS book of 431 pages contains a vast amount of information, in a concentrated form, for the use of manufacturing chemists, agriculturists, arboriculturists and horticulturists. Originally a French work, now in its second edition in English, it is the result of many experimenst in the field and laboratory, in many countries, and deals with the use of many chemicals, *bouillies* (French term for mixtures), and even hot and cold water. Diseases are due to physical, chemical and parasitic causes. It may surprise the ordinary reader to learn that the hearts of Cabbages, curds of Cauliflowers and sprouts of Brussels Sprouts are due to a disease named parenchymatosis, imparted to them by excessive nitrogenous feeding for several generations. When they revert to the wild condition of the Cabbage as a result of drought or starvation, that is a relative disease.

It will soon become evident to the observant reader that he or she must know something about the life history of the insect or fungus to be destroyed, and also the effect of the insecticide or fungicide upon the plant, if used in excess of that found to be permissible. Admonitions and warnings are of constant occurrence on this point.

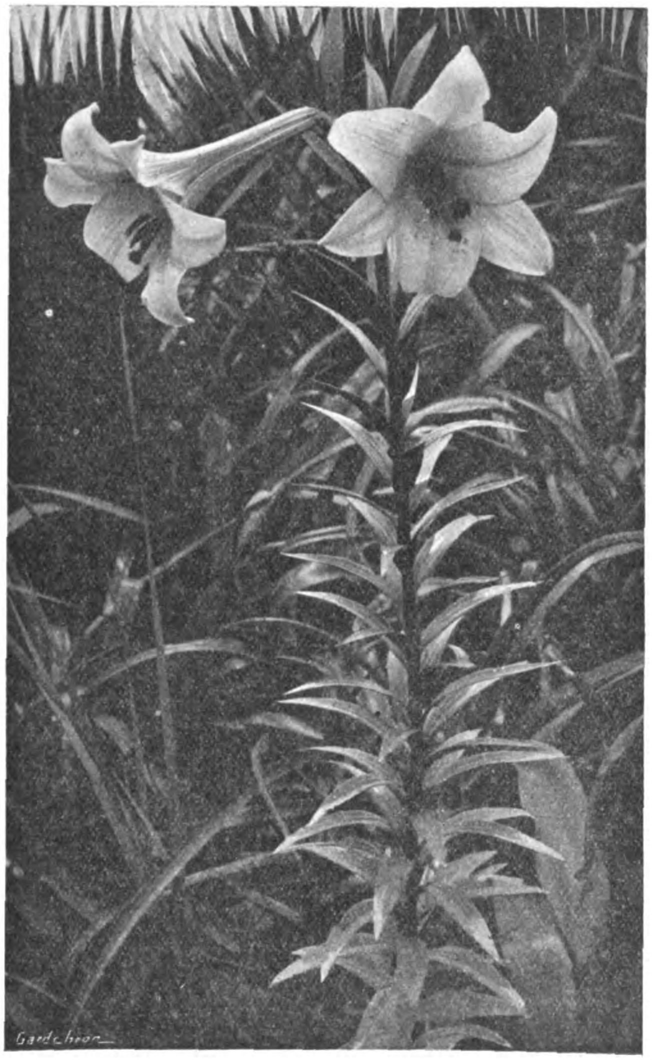

FIG. 35.—LILIUM NEILGHERRENSE IN MRS. BERRIDGE'S GARDEN AT OOTACAMUND, 1925.

(see p. 65).

The submersion of fields and meadows with water has been practised to kill cockchafers and other root-eating insects; of forests to kill cockchafers, Hylobius and other enemies of Conifers; and of vineyards to destroy phylloxera. All this must be limited within definite periods, especially in the case of fruiting vines that may have the quality of the crop greatly deteriorated by the submersion of the roots. Hot water may be used for killing insects and fungi at some temperature below the boiling point of water, and this varies with the sensitiveness of the fungus or insect, and the resistance of the foliage to heat. Seeds supposed to be coated with the spores of certain diseases may be treated with hot water. It should be a relief to many gardeners to know that caterpillars on the Cabbage tribe may be destroyed by water at a temperature of 131°F., because poisons must not be employed.

The uses of sulphur as a fungicide are many and varied, and every expert gardener knows how to contend with mildew in the vinery. It may interest him to know that 100,000 tons of sulphur are used annually in the vineyards of France. Many are the uses of potassium polysulphides; and liver of sulphur, in common use, is a mixture of polysulphides. Many instances are given of common and uncommon diseases of plants to which this remedy may be applied. Calcium sulphides (lime-sulphur) are less injurious to plants than potassium sulphides, because thay are not caustic. Insects are more sensitive to carbon disulphide than are plants, and directions are given for its use in certain cases. Many other chemicals, in use against plant enemies, are dealt with in a scientific way, those that are ineffective being indicated. Amidst a plethora of instructions the reader will be able to find what he wants by referring to the copious index, if he knows the insect, insecticide, fungus or fungicide with which he wishes to deal.

**Insecticides, Fungicides and Weed Killers.* By E. Bourcart, D.Sc. Second Edition, Revised and Enlarged by Thomas R. Burton. London: Scott, Greenwood and Son, 8, Broadway, Ludgate, E.C. 4. 1925. Price 15s. net

The book is well edited and contains few errors, but surely the American specialists were misquoted, where the rot of Potatos is said to be due to Oospora scabies: and Potato scab to an aerobic bacteria! The names of the causes of the disease might be transposed to advantage. There are eighty-four tables and thirteen illustrations in the text.

VINE BORDERS.

The proper treatment of the vine border in winter is an important detail in Grape-growing, for no matter what care is given to the vine the crop will not be a satisfactory one if the border is neglected.

There is no time like the present for putting the border into proper condition. The first item to be considered is efficient drainage; surplus water should be able to run readily through the soil, for stagnation at the roots is detrimental to vines and hinders their growth. Where the subsoil is clay, artificial drainage is necessary. A simple method of dealing with this difficulty is to make the bottom of the borders in V-shape, say two feet deep at the sides and gradually deeper in the middle until it is about three feet in the centre of the house. When the borders are made in this manner the water, after passing through the soil, will run to the lowest part in the middle of the house. It is a good plan to fill the bottom of the border with stones, clinkers or broken bricks to facilitate quick drainage. In the case of established borders that are badly drained, the only remedy is to make a trench around the border and fill in with builders' refuse, this making the border sweet and assisting the vines considerably.

The nature of the soil used in the border has a great influence on the growth of the vines and their crops. Old garden soil of a dark colour, due largely to the presence of a liberal amount of decayed vegetable matter, although perhaps splendid for other fruits, is not suited to Grapes, causing them to colour badly.

Soil that does not contain sufficient decayed vegetable matter is also unsuited to vines, for in such a medium the growth is small and the Grapes undersized. Dark, rich soil will, as a rule, produce plenty of growth, and with proper treatment, good sized berries, but the trouble is that the latter shank and colour badly. A soil of this nature should receive a liberal dressing of basic slag and sulphate of potash in the winter, at the rate of three-and-a-half pounds of slag to one pound of potash: all animal manures should be excluded. Soils that are deficient in decayed vegetable matter need the reverse treatment, that is, plenty of well-decayed manure. A good mixture is as follows:—Two barrowloads of well-decayed manure, two pounds of bone-meal, two pounds of superphosphate of lime, and one pound of sulphate of potash, which will be sufficient for each vine. For soils of a heavy, clayey nature, the following manures should be used. One barrowload of horse manure, two pounds of basic slag, two pounds of bone-meal and one pound of sulphate of potash: for sandy soils one barrow-load of cow manure, two pounds of bone-meal, one pound of sulphate of potash, and one pound of superphosphate: for chalky soils, one barrow-load of cow manure, three pounds of super-phosphate, one pound of kainit and one pound of hoof and horn manure to each vine.

Some little care must be given in the application of these manures. The first thing to determine is the position of the roots, for upon this depends the treatment. Remove the soil carefully from the roots of one vine, until they are all reached. It often happens that the roots near the vine are close to the surface, and some may be near the surface for several yards, or they may be growing deeply in the soil. The grower should endeavour to get them nearer the surface and keep them there. When the roots are reached commence to fill in with prepared soil, and spread the manure over the border with a fork, working it well into the soil. After the border is finished, the roots near the surface should be given a good mulching of manure, about two inches deep, and this should be retained until the Grapes start to develop colour. *G. B.*

FRUIT REGISTER.

APPLE ANNIE ELIZABETH.

Fruit growers are fortunate in having so many excellent varieties of late culinary Apples at their disposal for planting, as the exhibit made by Messrs. G. Bunyard and Co. at the last R.H.S. meeting demonstrated, the many first-rate culinary sorts they exhibited being in splendid condition at this late season of the year. The wealth of good sorts makes the selection for those who intend to plant late culinary Apples a rather difficult matter. Certain varieties, however, are not a success in some districts as in others, and growers should take care to observe the behaviour of particular varieties in their immediate neighbourhood. Those who plant Annie Elizabeth may have no fear of it being a success, for it is one of the very best late culinary Apples in cultivation. The fruits are large, those in the illustration reproduced in Fig. 36 being much reduced, and their contour is even, which is a desirable quality in a cooking Apple, as there is not much waste in removing the skin.

The fruits are very firm and solid and remain so until late in the New Year, for this fine Apple will keep until June. The skin is exceptionally attractive owing to the brilliant red colour which covers almost the whole of the surface. A peculiar feature of this variety is the hammered appearance of the skin, a character by which it may be readily recognised.

Bunyard in *A Handbook of Fruits* states that it is a valuable variety deserving of extended cultivation. The tree is a good grower with an upright habit, and when well established is a free cropper. The flesh is crisp, juicy, white, and as stated, of very firm texture, the flavour being brisk and somewhat acid. This late Apple was raised by Mr. Greatorex, at Leicester, and was introduced to cultivation by Messrs. Harrison of Leicester, who, in 1868, received a First Class Certificate for the variety from the Royal Horticultural Society.

APPLE BLENHEIM PIPPIN.

I have often heard the opinion expressed by well-known fruit growers that there are several types of Blenheim Pippin in cultivation, indeed, they are often spoken of as "seedling Blenheims." It would be interesting to know if these forms are really seedlings or whether they are merely sports.

Seeing that the variety Blenheim Pippin was not cultivated in nurseries until about 1818, it cannot be regarded as one of the oldest of Apples, for there are some which date back to Chaucer's time and perhaps longer.

That Apples undoubtedly sport is proved by the coloured forms of such well-known Apples as Bramley's Seedling and James Grieve.

It might serve a useful purpose if an institution, such as Wisley, planted as many of these so-called forms of Blenheim Pippin as could be obtained to ascertain if they are really distinct and whether any possess superior qualities in cropping, etc. *T.*

PEAR PRESIDENT BARABE.

I could name several late-ripening Pears, but not one equal to President Barabe for flavour at Christmas and the New Year. It is an invaluable variety, but requires the protection of a south wall in this county, and succeeds best when double-grafted on the Quince stock. *Wm. Allan, Gunton Park Gardens, Norwich.*

[The specimens sent with this note were of fine size, handsome appearance and excellent flavour, fully bearing out Mr. Allan's observations. Eds.]

HOME CORRESPONDENCE.

Polygonum baldschuanicum or P. Aubertii.—There seems to be confliction regarding the nomenclature of Polygonum baldschuanicum and Polygonum Aubertii. While one nursery catalogue describes the former as blush pink, and the latter as white, another gives the reverse descriptions, whilst still another gives both as white, P. Aubertii being regarded as a strong form of P. baldschuanicum. We have a quantity of P. baldschuanicum in this garden, and I have noticed that although mainly white, sometimes a tinge of pink is noticeable in the flowers, P. Aubertii, as I knew it, about four years ago, was quite white. When at Wisley last summer, I saw a plant in full bloom that was quite a distinct Peach-blossom pink, but could see no label. Perhaps some obliging lover of this plant would put me right on the subject, and, at the same time, I should be grateful to know where the true pink form can be obtained. It may be that the nature of the soil causes the pink tinge, as although we have two large groups of this Polygonum, far apart, only one shows the pinkish tint. *R. Gardner, Heywood Gardens, Cobham, Surrey.*

Does Frost Kill Insects?—There is a very general opinion amongst gardeners that frost kills insects. My own very limited observations on this subject tend rather to disprove this idea. One reads frequently that good hard winters are beneficial in that they kill insect pests. Is it not a fact that we often get heavy insect attacks following severe winters; *e.g.*, here in Yorkshire we had much frost during the winter of 1923-24, yet the summer of 1924 was a bad one for insect attacks, especially Gooseberry sawfly (Nematus ribesii). I should like to ask through the columns of *The Gardeners' Chronicle*: (1) Is there any real evidence that frost will kill insects? (2) What evidence have we that frost helps to control insect pests? May I be permitted to point out that observations and not opinions will help to clear up the matter. *G. C. Johnson, Leeds.*

Romneya Coulteri.—In reply to Mr. A. T. Harrison's request that other growers of Romneya Coulteri should give their experience of its habit of growth, I am glad to give mine, as this plant has puzzled me also. Some five and twenty years ago I obtained a plant under the name of Romneya Coulteri from Messrs. Backhouse, of York, for my garden on the estuary of the Dart, where it flourished exceedingly and sent out quantities of suckers which I found, if removed in April and planted elsewhere, grew at once, and formed new bushes. I left that garden, and, later, purchased another plant from Messrs. Thompson and Morgan, of Ipswich, for my present garden in the Isle of Wight. This plant has not sent out a single sucker (nor did my plant of R. trichocalyx). I believe there are two forms of R. Coulteri—one that sends out stolens, and one of simple bush form. I believe, too, that there is a difference in the matter of scent. No one, to my knowledge, has ever mentioned that the flower buds of R. Coulteri and R. trichocalyx are quite different—the latter's being globose, whereas those of the former are Pineapple-shaped, and were so in both of my plants. Both R. Coulteri and R. trichocalyx died in this garden; perhaps they do not like greensand. *C. M. B., Isle of Wight.*

——I read with interest the article on Romneya Coulteri on page 6 of *The Gardeners' Chronicle* for January 2, by A. T. Harrison. I also read the former article on page 428 (1925) by A. T. Johnson, and I can fully substantiate Mr. Johnson's mode of propagation, as for years I had a very fine plant of this beautiful Poppy in my own garden. It was planted in the shelter of an old tree of Dartmouth Crab, as I had been told it was not hardy in this district; but it threw such a quantity of suckers that—although beautiful—it became, year after year, more or less a nuisance as the suckers extended yards; they came through the Box edging, tangled themselves in the roots of the Crab, and even penetrated my gravel paths, although the foundations of these paths were old bricks laid side by side for solidity. Eventually I dug it up, and for two years the broken suckers still continued to thrive until I removed the brick foundation, when I found they had pushed themselves up through the holes in the bricks, almost as freely as Bindweed. Very fine plants from these suckers can still be seen in a well-known local nursery here, where R. Coulteri grows quite freely. If Mr. Harrison has any doubt as to my plant not being true R. Coulteri and will kindly furnish me with his address, I shall be most pleased to send him flowers and foliage for his inspection in due season. *Geo. Wyatt, Northernhay, Huntingdon.*

——In reply to Mr. A. T. Harrison, and with all due respect to his opinions and those of M. Correvon, I believe the Californian Bush Poppy I have here, and referred to as suckering freely, is R. Coulteri and not R. trichocalyx. Obviously, I cannot demonstrate its identity at this season in the only reliable way—by the calyx, but I have not any doubt whatsoever that this is devoid of the bristling hairs of R. trichocalyx. Further, I do not think that R. trichocalyx has the stature (seven feet) and bold upright form of my plant, most authorities agreeing that it is dwarfer and more spreading. As to the suckering, I am aware that this may not be a common feature in young specimens of R. Coulteri. That much I inferred in the note criticised by Mr. Harrison by stating that this species " suckers freely, especially when old," and to that I rigidly adhere. Mr. W. J. Bean, an authority on trees and shrubs, states (*Trees and Shrubs Hardy in the British Isles*) that the young shoots springing from the roots of old plants of R. Coulteri can be used for propagating, and that is precisely my own experience. *A. T. Johnson, Taly Cafn, N. Wales.*

Rainfall at Tirley Garth in 1925.—Rainfall at Tirley Garth Gardens, Tarporley, for the year 1925, amounted to 33.03 inches, or 1.63 inches less than in 1924. The heaviest rainfall occurred on May 19, when 1.59 inch was registered. June was the driest month of the year with only .10 inch. In May the rainfall amounted to 5.07 inches, this being the wettest month in the year with twenty-one rainy days. There were 198 days on which .01 of an inch or more was registered, and 153 in which .04 or more was registered. The driest spell was from the 1st to the 15th of June, when we had fourteen clear, dry days. The hottest day was on June 10, when the temperature rose to 90° in the shade. The coldest days were on December 1 and 22, when 14° of frost were registered. From December 6 to the end of the year there was rain almost every day. *James B. Allan, Tirley Garth Gardens, Cheshire.*

Garrya elliptica.—In his note on this shrub (page 6), Mr. Harrison refers to the legend that the brothers Adam adapted from its male catkins the characteristic feature which occurs so frequently in their mural decoration. It is true that these catkins would have served very well as a model for that particular design; but it is impossible that any of the three brothers Adam could have so employed them, for as much as William Adam died in 1748, Robert in 1792 and James in 1794; whereas it was not until 1828 that Douglas introduced Garrya elliptica to this country from north-west America. *Herbert Maxwell, Monreith.*

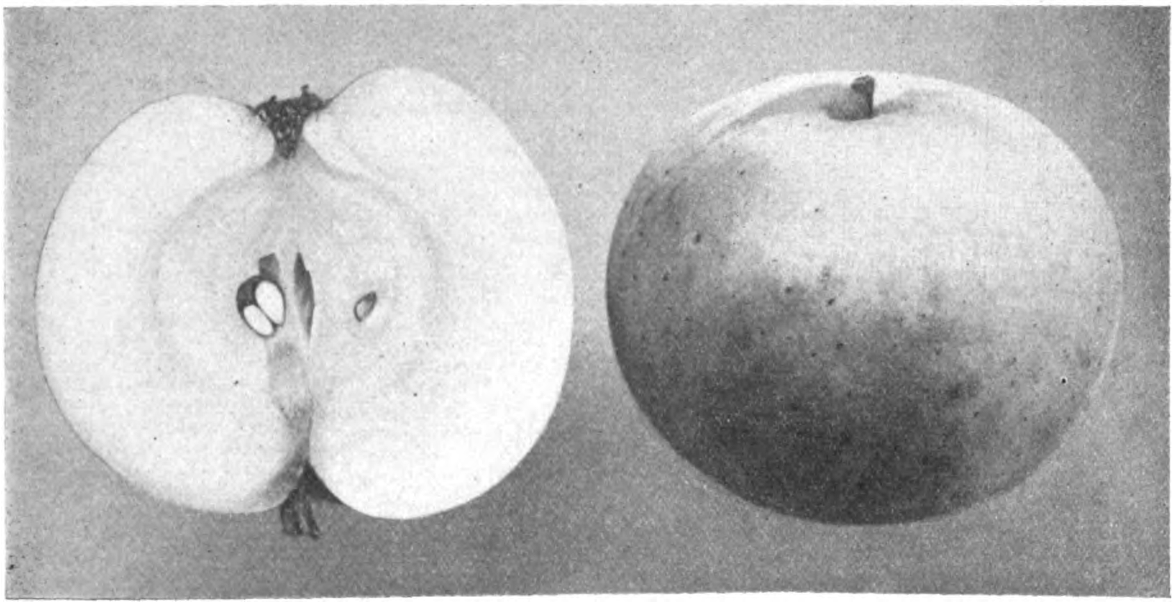

FIG. 36.—APPLE ANNIE ELIZABETH.
(see p. 68).

PUBLIC PARKS AND GARDENS.

THE East Barnet Urban District Council has under consideration a letter from the agents of Mr. W. A. Vernon on the question of land in East Barnet village for a recreation ground.

BOGNOR Urban District Council has confirmed the making of a provisional offer of £8,000 for the purchase of The Den, Upper Bognor, as pleasure and recreation grounds.

THE Urban District Council of Camborne is considering the provision of recreation grounds at Troon and Tuckingmill.

THE Glasgow Parks Committee propose to demolish the lodge at the main entrance gate of Loch Lomond Park, and to erect a new one. It is recommended that four additional tennis courts be constructed in Alexandra Park and Glasgow Green, and that the footpaths in George Square be laid with granolithic, and the centre with natural mastic rock asphalte, at an estimated cost of £5,000.

THE Urban District Council of Solihull has received sanction from the Ministry of Health to borrow £4,800 for purchasing part of the Malvern Park Estate, Solihull, for use as a public recreation ground.

SOCIETIES.

GUILDFORD AND DISTRICT GARDENERS'.

THE President, Alderman W. T. Patrick, J.P., presided over a large attendance at the December meeting, 1925, when Mr. F. J. Chittenden, of Wisley, gave a lecture on " The Germination of Seeds," a subject which he made both instructive and interesting. Taking a Pea as an illustration, the lecturer explained that the seed contained two leaves, a stem and a root. It was in fact a small plant already made but awaiting development. The food material contained within it was food stored up by the parent plant to give the next generation a start in life, at a time when the young plant could not obtain food for itself. Coming to the matter of germination it was pointed out that plant life had much in common with animal life, and must have water, air and warmth. Expanding this theme Mr. Chittenden gave proof of his wide knowledge of the subject and held the attention of his hearers, who certainly left the meeting wiser than they came.

A striking tribute was paid to the lecturer by Mr. J. A. Kirkwood, an expert professional gardener, who, speaking to a vote of thanks, said that Mr. Chittenden had taught them a great deal that night, and in future he should give greater heed than before to the important subject of germination.

In closing the meeting Mr. Patrick made feeling and appropriate reference to the sudden and lamentable death of Mr. Dykes, the secretary of the R.H.S,, and on behalf of the Guildford Gardeners he undertook to convey to Mrs. Dykes an expression of sincere sympathy at the loss of her husband, and to the staff of the R.H.S. at Wisley.

READING AND DISTRICT GARDENERS'.

THE annual meeting was held in the Abbey Hall on Monday, the 11th inst., and was presided over by the President, Mr. Frank E. Moring. The annual report and balance sheet, as read by the hon. secretary and hon. treasurer, respectively, showed that the association was in a very flourishing condition. The meetings during 1925 had been largely attended, the lectures had been unusually good and the discussions well maintained. The exhibits, both in the competitive and non-competitive sections, had been well up to the standard. Finance, and membership were alike, excellent. The following were elected to the various offices for 1926 :—President—Mr. Frank E. Moring ; Vice-presidents—The Mayor of Reading, Mr. Leonard Sutton, C.B.E., J.P. ; Ald. F. B. Parfitt, J.P. ; and E. P. Foquett Sutton, M.B.E. Chairman—Mr. F. J. Green, The Gardens, Aldermaston Court ; Vice-chairman, Mr. J. R. Lloyd, University College Gardens, Shinfield. Hon. Treasurer—Mr. A. H. Leaver ; Committee, Messrs. H. Broomfield, G. Carter, W. Chislett, C. S. Clacy, A. J. Cobb, H. H. Cook, A. H. Dow, A. H. Finker, M. Goddard, F. Goodger, A. W. Gower, C. J. Howlett, H. C. Loader, T. Martin, C. Moulton, H. Reeves, F. Townsend, H. Wynn, J. Wynn and J. Young ; Hon. Secretary ; Mr. H. G. Cox —Assistant Hon. Secretary—Mr. E. J. Dore.

NORTH OF ENGLAND HORTICULTURAL.

Mr. Hebbert Frankling presided over the annual meeting of this Society, held at Harrogate in December last.

The secretary, Rev. J. Bernard Hall, presented the report of the committee which showed that notwithstanding increased expenditure, the Society concluded its financial year with total cash assets of £114 12s. The April show was well supported by the trade, but it involved a loss of about £25. The September show was a success, thanks to generous help from the Harrogate Chamber of Trade. Reference was made to Mr. W. W. Pettigrew's lecture on "Training Lads in Horticulture" (published in our columns), and to the progress made with regard to the establishment of a North of England Trials Station. After much preliminary work the R.H.S. called a conference at the Chelsea Show on the 20th May, and the proposal was keenly discussed by representatives from corporations and societies in the North of England and Scotland. The delegates from over the border were from the Royal Caledonian Horticultural Society (Edinburgh), the Royal Horticultural Society of Aberdeen, the Glasgow the West of Scotland Horticultural Society and the Horticultural Trades' Association. Delegates present from the North of England represented the Lancashire County Council, Manchester Corporation, the Department of Agriculture, The University, Leeds ; Leeds Corporation, and seven menbers of the N.E.H.S. Council. After deliberating among themselves, the delegates agreed to work in two sections. Unfortunately, the Scottish section has not been able to report progress, and in Scotland the feeling is general that the R.H.S. should take the initiative and conduct the trials. With regard to the North of England, it is satisfactory to report that the Education Committee of the Lancashire County Council reports that "the establishment of a station of this kind would be an advantage to growers in the North of England" and "they were prepared to provide land and other facilities at Hutton, near Preston," and "give the Society all possible help in the matter." Harrogate Corporation has continued its welcome interest, and has generously offered, at a nominal rent, sufficient land to commence operations, 550 feet above sea-level, close to a first-class meteorological station. An extension of the land would be possible in the future. A sub-committee of inspection was appointed at York Gala to visit the site. A favourable report drawn up by Mr. A. S. Galt, Horticultural Organiser to the Agricultural Committee of Yorkshire has been received, the sub-committee being satisfied as to the suitability of the land. It is quite evident that there is a consensus of opinion as to the absolute need for such a trials ground, and sufficient offers of subscriptions and donations have been forthcoming to encourage the N.E.H.S. to issue a special public appeal when the time is ripe. Owing to the tragic decease of Mr. W. R. Dykes, Secretary of the R.H.S., negotiations with the Council of the R.H.S. are in abeyance, and the North of England awaits their pleasure in the matter, since their co-operation is essential to success. Mr. W. G. Lobjoit, Controller of Horticulture, put forward a suggestion at the Trials Conference at the September show, namely, that the University of Leeds should supply the official scientific recorder for the trials, this being useful public work. This suggestion has been forwarded to the Department of Agriculture, The University, Leeds. Several prominent Fellows of the Royal Horticultural Society have visited the suggested site of the trials ground at Harrogate. Mr. Jos. Cheal has taken a keen interest in the matter, and Mr. H. L. Wettern, for many years amateur Rose champion of England, has generously presented the Council of the N.E.H.S. with plans and elaborate coloured sketches drawn up by Mr. George Dillistone, garden architect, of Tunbridge Wells.

After the report had been adopted, the chairman presented the Founders' Silver Plaque for the ensuing year to Mr. J. Mallender, of Scrooby, in recognition of his work as a raiser of Daffodils and his assistance to the Society. The retiring members of Council were re-elected, and nine others added to bring the number of members of Council to twenty-four. The additions are: Mr. A. S. Galt (Leeds), Mr. J. G. Besant (parks superintendent, Harrogate), Mr. C. W. H. Greaves (Knaresborough), Mr. H. S. Wainwright (Leeds), Mr. L. Radcliffe (Bradford), Viscountess Mountgarret, Lady Barren, Lady Cunliffe-Lister and Lady Peel.

Following a discussion of an educational scheme for horticulturists, the meeting closed with thanks to officers and chairman.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

At the monthly meeting of this Society' held in the R.H.S. Hall, on Monday, January 11, Mr. Chas. H. Curtis presided, and ten new members were elected. Seven members withdrew interest from their deposit accounts amounting to £26 17s. 5d., and three members over the age of seventy years withdrew sums amounting to £71 4s. 6d. The death of two members was recorded, and the sums of £122 0s. 5d. and £35 12s. 2d, respectively, were passed for payment to their nominees, while £17 19s. 1d. was passed for payment to one deceased lapsed member. Sick pay for the month on the Ordinary side came to £121 19s. 10s., and on the State section to £121 15s. 6d. ; maternity benefits totalled £9 10s. 0d. Grants were made to eight members of the State section for dental and optical treatment, amounting to £22 17s. 0d ; ten other cases were considered.

ROYAL HORTICULTURAL.

Trial of Turnips.

The following awards have been made to Turnips by the Royal Horticultural Society after trial at Wisley. The varieties in brackets are alike.

Highly Commended.

(Early Red Milan, sent by Messrs. J. Kelway and Son, and Messrs. Ed. Webb and Sons, Ltd. ; Red Top Milan, sent by Messrs. J. Carter and Co.) ; (Snowball, sent by Mr. Wiboltt and Messrs. Nutting and Sons, Ltd. ; Model or Snowball, sent by Messrs. R. Veitch and Son ; Covent Garden Snowball, sent by Messrs. Barr and Sons ; Snowball Improved, sent by Mr. Olsen ; Model, sent by Messrs. Watkins and Simpson and Mr. W. H. Simpson ; Model White, sent by Mr. Cullen and Messrs. Dobbie and Co.) ; (Early Red Top Globe, sent by Messrs. Cooper, Taber and Co., Ltd. ; Red Garden Globe, sent by Messrs. R. Veitch and Son ; Red Globe, sent by Mr. Cullen and Mr. W. H. Simpson ; Red Globe Selected, sent by Messrs. Dobbie and Co.) ; (Chirk Castle, sent by Mr. Cullen, Mr. W. H. Simpson and Messrs. J. Carter and Co. ; Chirk Castle Black Stone, sent by Messrs. Barr and Sons and Messrs. Dickson and Robinson).

Commended.

Extra Early Milan, sent by Messrs. R. Veitch and Son ; Early Milan, sent by Mr. W. H. Simpson and Messrs. Dobbie and Co. ; White Milan, sent by Messrs. Cooper, Taber and Co., Ltd.) ; (Early White Dutch, sent by Messrs. Dobbie and Co. ; White Flat Dutch, sent by Mr. Daehnfeldt ; Early White Globe Strap leaved, sent by Messrs. Cooper, Taber and Co. Ltd.) ; (Green Top Stone, sent by Messrs. Barr and Sons, Mr. W. H. Simpson and Mr. Cullen ; Stone Green Top, sent by Messrs. J. Kelway and Son) ; Yellow Maltese Improved, sent by Messrs. J. Carter and Co. ; Sunrise, sent by Messrs. J. Carter and Co. ; (Golden Ball, sent by Messrs. Cooper, Taber and Co., Ltd., Messrs. Kelway and Son, Mr. Cullen, Mr. Daehnfeldt, Mr. W. H. Simpson, Messrs. Watkins and Simpson, Messrs. Dobbie and Co., and Mr. Wiboltt ; Orange Jelly or Golden Ball, sent by Messrs. Ed. Webb and Sons ; Orange Jelly Selected, sent by Messrs. Barr and Sons ; Golden Ball Improved, sent by Mr. Olsen ; Golden Rose, sent by Messrs. J. Carter and Co.).

NATIONAL ROSE.

There was a good attendance of members at the annual general meeting of the National Rose Society held at Caxton Hall, Westminster, on the 19th inst. Mr. C. C. Williamson presided, and he was supported by the hon. secretary, Mr. Courtney Page; the hon. treasurer. Mr. S. A. R. Preston-Hillary ; Mr. E. J. Holland and Mr. H. R. Darlington. The ladies present included Miss Ellen Willmott, Mrs. H. R. Darlington, Mrs. E. J. Holland and Mrs. F. Courtney-Page.

There were also present Mr. Frank Cant, Mr. J. S. Harvey Cant, Mr. H. W. Drew, Mr. A. R. Bide, Mr. Walter Easlea, Mr. J. Cheal, Mr. W. E. Wallace, Mr. A. C. Turner, Mr. A. Johnson, Rev. F. R. Burnside, Mr. Sidney F. Jackson, Mr. J. N. Hart, Mr. W. E. Moore, Rev. J. H. Pemberton and Mr. George Marriott.

The annual report of the council, which was printed and circulated, was taken as read, and in proposing its adoption, the chairman referred to the loss the Society has sustained by the death of its Patron, Queen Alexandra, and then congratulated the Society on its continued prosperity. Mr. E. J. Holland seconded the adoption of the report in a characteristically pleasant speech, and said that the nominations being equal to the vacancies, there was no election for seats on the council. With regard to the paragraph of the report which reminded the members that the Society was always ready and willing to give advice on Rose matters, Mr. Holland appealed for moderation in such requests, because there was a certain danger of the secretary being overwhelmed, especially when, as had happened, one member asked thirty-nine different questions in one letter. It was more than likely, he said, that the autumn show would be held at the R.H.S. Hall again, because although on the two occasions when the show had been held out-of-doors they had been very successful, the council felt, that in view of the uncertainty of the weather so late in the year, it was tempting the fates too much, as a wet day would ruin the show and spoil the members' pleasure. Mr. Holland referred to what he felicitously termed the goodly heritage of the Society's publication, which contained, he said, a wealth of information obtainable nowhere else.

As the report was, presumably, open to discussion, and with it the Society's affairs, Mr. F. S. Harvey-Cant protested against the action of the council in transferring the Championship Trophy from the exhibition Roses to the decorative Roses. He contended that the change was not in the best interests of the Society and the Rose. The Trophy was no longer a "super-award for super Roses," but one for the exhibitor with the most decorative skill who need not be a first-rate producer. The change, he felt convinced, would adversely affect the affiliated societies, as they would follow the example of the N.R.S., and the result would be that, as few growers could furnish sufficient exhibits to attend the smaller shows, which depended on the trade for their displays of Roses, the flower itself would, in his opinion, suffer, as the change would unduly give fictitious value to the type of Rose which is attractive in a show group, but has little value in the garden. Mr. F. S. Harvey-Cant therefore proposed that the question of the allocation of the Championship Trophy be referred back to the Council. The chairman ruled Mr. Cant out of order, and said that the change had been agreed by the council. The Rev. J. H. Pemberton then stated that the change really opened the door to all Roses, and the Trophy might be won by any and not by one section of the Rose.

Miss Willmott remarked that she heartily endorsed the mention of the great interest Queen Alexandra had taken in the Society, and knew that Her Majesty had put attendance at the summer show before other affairs.

In submitting the "summary" of Accounts Mr. Preston-Hillary made reference to nearly all the items. Regarding the substantial increase in the receipts from subscriptions, he said the whole credit was due to the untiring efforts of the hon. secretary—a tribute in which all present heartily agreed. There was, he said, one outstanding account of £800, due to the printers, but as this was for publications shortly to be circulated he felt that it properly belonged to the present year. He deprecated any increase in the amount which had been spent in prizes, for he was of the opinion that the £866 odd was quite as much as the Society could afford.

Mr. H. R. Darlington seconded the adoption of the Summary of Accounts, and said that he felt that *The Rose Annual* was of especial value if only because it was the only means the Council had of addressing the 13,000 members. The *Enemies of the Rose* had been revised, and was of increased value. He expressed the opinion that there was a distinct need for greater office accommodation. He would like the Society to have a separate room for its fast-growing library, so that members could call and consult the books without disorganising the office work as at present.

The adoption of the report and summary of accounts was then carried without further comment, and the Dean Hole Memorial Gold Medal was presented to Mr. Courtney Page. In making the presentation, the chairman said that the council felt there was no one living who deserved the honour more than Mr. Courtney Page, who, he said, was, in his modesty, an unwilling recipient. Mr. Page has been a member of the Society for thirty-two years, and a member of the council for twenty-five years, and the present prosperity of the Society is largely due to Mr. Courtney-Page, who has worked untiringly on the Society's behalf. Mr. Courtney-Page, who was enthusiastically received, said that the present was, to him, one of the occasions when one would wish to say a great deal but felt unable to do so, but he thanked the meeting sincerely for the great honour.

As, according to rule, the officers had all been duly nominated and there were no other names presented there was no election, but they were all thanked for their services. Mr. Frank Cant then proposed a vote of thanks to the chairman, and the meeting closed, after which tea was provided for the members.

TRADE NOTE.

FOR the encouragement of children Mr. Clarence Elliott is offering this year a special collection of twelve packets of easily grown flower seeds, suitable for children's gardens. All are annuals, and each packet has a coloured illustration of the kind or variety and directions for growing. He is offering fifteen prizes for the best results obtained from this collection of seeds by children under fifteen years of age. The first prize consists of a spade, a fork, a hoe, a rake, a trowel, a hand fork, a watering can, and a gardener's basket. The second prize is like the first, but without the basket; and the third prize is like the second, without the watering can. There are also twelve consolation prizes. As it is impossible to judge the competing gardens the prizes will be awarded for the fifteen best sets of pressed specimens of six flowers grown by competitors from these seeds. The flowers, with leaf and stem should be pressed, and then mounted on a sheet of cardboard twelve inches long and nine inches wide.

ANSWERS TO CORRESPONDENTS.

APPLES FAILING TO KEEP. *Mrs. C.* The Apples are rotting from the attack of various parasitic fungi which cause the "ripe rots" of stored Apples. These fungi enter through small wounds in the skin of the Apple. Care should be taken not to bruise Apples when gathering them. Stored fruits should be examined frequently and the rotting Apples removed.

CONCRETE GARDEN PATHS. *B. C.* By the aid of a bag or two of Portland cement and a few barrow-loads of gravel and sand, a concrete path may be provided which will be neat, clean and durable. The method is simplicity itself. Take four parts (by volume) of clean sand and gravel, and mix thoroughly with one part of Portland cement on a non-absorbent floor or other surface. Afterwards add water gently and gradually, mixing all the time until a stiff paste is obtained. When set, this mixture will be concrete, and may be moulded into any desired shape. By the use of a little pigment, the concrete may be coloured any shade. For a plain concrete path, fix down each side a strip of wood about one-and-a-half-inch thick and three inches deep, and fill in with the wet mixture, levelling off with a "float" (a slab of wood with a handle). Should slabs be preferred, make a few plain, rectangular boxes, without top or bottom, and hinged so that they come apart easily. Fasten these down to a baseboard, fill with concrete, and leave for a couple of days; the slabs will then be ready. During bad weather these slabs may be made in an outhouse and stored for future use. If "crazy" paving is desired break the slabs into irregular pieces and lay them in a bed of cement mortar. Just one caution: Do not mix more concrete at one time than can be used within an hour, because in about that time it begins to set, after which it must not be disturbed. The secret of success in concrete work is thoroughness.

GARDENER'S HOUSE AND NOTICE.—*O. R.* Unless any special arrangement was made at the time of your engagement, either side could terminate your engagement on giving one month's notice, and this appears to have been given to you. You are not entitled, therefore, to claim any compensation and if your occupation of the house was part of your wages, you must, on the expiration of the notice, give up possession or your employer would be entitled to take proceedings in the County Court.

MUSSEL SCALE ON PLUM TREES. *J. A. E.* The Plum shoots are affected with Mussel Scale. Where only a moderate number of scales are present they may be removed by scraping the bark and scrubbing the latter with some strong specific, such as caustic alkali. In using this strong chemical the hands should be protected with a pair of gloves. If, however, the trees are very badly affected, the only course is to uproot them and destroy them on the garden fire.

NAMES OF FRUITS. *A. T. L.* Brabant Bellefleur (syn. Glory of Flanders). *Mrs. I.* Bastard Blenheim.

ROSE LEAVES DISEASED. *W. F.* The Rose leaves show three kinds of spots: yellowish, erumpent spots on the under surface which contain the summer spores (uredospores) of the Rose rust (Phragmidium subcorticium) blackish erumpent spots also on the lower surface, which are the winter spores (teleutospores) of the same fungus; whereas one or two leaflets show on the upper surface the flat, purplish spots with yellowish centre which are characteristic of leaf scorch (Septoria Rosae). The last-named fungus appears to be only secondary, and is located chiefly where the old attacks of Phragmidium have been. The fungus, as a rule, is not a very serious pest, though when it causes cracking of the branches it is very unsightly. The usual methods of prevention and cure are (1) the collecting and burning of the old diseased leaves both from the bush and from the ground; (2) spraying, just before the leaves begin to expand, with liver of sulphur (one ounce to two or three gallons of water), or with potassium permanganate solution (one ounce to five pints of water with two ounces of soap added.)

SPECIMEN CHRYSANTHEMUMS. *E. B. W.* To obtain large specimen Chrysanthemums it is desirable to select plants rooted during December, especially when dealing with large exhibition varieties. The plants should be pinched until the required number of shoots are obtained, it may be twelve or more, this largely depending on the individual variety. It is much easier to grow large specimens of single and small-flowered Japanese varieties, with twenty-four or more good blooms. The cuttings are best rooted singly in small pots, as there is little or no check when they are potted the first time. Stopping will depend to a great extent on the varieties grown, but, as a rule, the required number of flowering shoots should be obtained about the beginning of July. The growths should be staked well apart, so that each shoot obtains the maximum amount of light and air. At one time, large Chrysanthemums, carrying 200 to 300 blooms, were exhibited, the cuttings being rooted during November; old plants were sometimes grown on into large specimens. You should be able to obtain good plants carrying twelve or more blooms in ten-inch pots. Among the large exhibition varieties Mrs. R. Luxford, Majestic and W. Turner may be selected, but only experience could prove which varieties in this section are best suited to your purpose. The stopping of these plants should not be done late in the season, May probably being the latest date for pinching. In the decorative section any of the varieties that are usually disbudded and are of a good habit should suit your purpose. Felton's Favourite, H. W. Thorpe, Sunshine, December Bronze, Nellie Pockett and Niveus being good types. Among incurved varieties, Souv. de W. Clibran, H. W. Thorpe and J. N. Streeter, make good specimens; while among the singles any of the varieties with a good habit may be selected for the purpose.

SHALLOTS. *G. G.* The Shallots are suffering from an attack of the fungus Botrytis which infected the bulbs in autumn, probably after they were lifted. The complaint is very prevalent this season owing to the poor ripening conditions during last autumn. There is no cure, and diseased bulbs should be burned. Shallots in store should be given dry, airy conditions to prevent infection of sound bulbs.

THE WEATHER, DECEMBER, 1925.

REMARKS.—The cold weather of November continued during the first week of December and then, after successive temporary mild breaks, was again and again renewed. Not until a day or two after Christmas did a permanent, warm, south-westerly current establish itself. The month was very sunny, and decidedly drier than usual; northerly winds being in excess, and southerly ones in defect. The mean temperature of the air was 38°, or 1¼° below the average; while that of the ground, at one foot beneath the surface, was so low as 34°, or nearly 4° below normal. Precipitation was measureable on twenty days, or one more than the average number; but the total quantity was only 2¼ inches, or almost an inch less than the normal. Sunshine was recorded on nineteen days, and amounted altogether to 51 hours, implying a surplus of 15 hours. Frost in the screen was registered on twelve nights, and "ground frost" on seventeen nights, but there were no minimum temperatures low enough to be noteworthy. Small falls of snow or sleet occurred on seven dates, but there was no hail. Thunder also was absent. Fog, mist and haze were again rather frequent. Brief gales were experienced on four days, the worst being a whole-gale on the night of the 30th, with a maximum hour's run of 62 miles for 10 p.m., and gusts up to a rate of 88¼ miles per hour. *Joseph Baxendell. The Fernley Observatory, Southport.*

REMARKS.—Chrysanthemum blooms, mostly of Cheshunt White and Favourite varieties are still arriving in good condition. Bronze Amber and Negoya are the best of the coloured blooms. There has been a considerable falling off in bunch Chrysanthemums, white being the most plentiful. Winter Cheer and Tuxedo are the best coloured varieties, but these are gradually becoming poorer in quality. Golden Spur Daffodils have increased in quantity and their prices are on the down grade; larger consignments are arriving from the Spalding district. A few blooms of Van Zion have been on sale during the past week. Tulips are the best so far offered this season, all blooms being much finer in quality; the newest arrivals are the double varieties—Couronne d'Or and Murillo. Wm. Copland is specially fine just now. Richardias (Arums) are much shorter in supply on account of the severe weather, and their prices reached 12/- to 15/- per doz. blooms on Saturday last. Lilium longiflorum is only in moderate demand, but its price remains firm. Carnations have maintained a steady trade, and their prices show little change from those of last week. Of Roses, Madame Butterfly is the best from home growers, and Ulrich Brunner the best from France. Consignments of French flowers have arrived in a very bad condition. On Thursday, Friday and Saturday last the contents of many packages were frozen and useless on arrival; their prices have fluctuated according to quality. The consignments this morning were more satisfactory, and prices will be normal in a day or so.

REMARKS.—Severe weather and snow are not helpful factors so far as the fruit trade is concerned, and business has been very much on the slow side during the past week. The demand for Apples has been fairly good, but the enquiries for Newtown and Jonathan have been poor. Some large, well-packed fruits of Bramley's Seedling continue to meet a good market, and Cox's Oragne Pippin in good condition is also selling freely. Various fruits from South Africa show expansion in quality with each weekly shipment. So far, Peaches, Apricots and Plums have met with a good demand from the buyers. English Grapes are a fair trade, as also are Grapes from Belgium. Oranges are inclined to be easier in quotation, but best Lemons are meeting a better inquiry, the cold weather probably creating a demand for hot Lemon drinks. Asparagus is a slow trade, both forced English and imported, being cheaper. Forced Beans from Guernsey and Worthing are scarce and costly, but new Potatos are meeting a quiet demand, as are new Potatos from the Azores, the Canary Islands and Algeria. Seakale is plentiful and comparatively cheap. Forced Rhubarb is not enquired for, and with fairly large quantities arriving each day, its prices are lower. Cultivated Mushrooms are a fairly steady business with no undue fluctuation in prices. Tomatos from the Canary Islands, when in condition and of good quality, are selling well. Cucumbers, mainly from the Worthing district, are expensive. Large numbers of Cauliflowers from Northern France have been very frosted, but generally, they have sold well. Lettuces from France are very plentiful, and as many consignments have suffered from frost, they have been difficult to sell, even at low prices. All green vegetables have been scarce and dear, but at the time of writing, an alteration in the section is evident. Trade in old Potatos continues steady with little or no change in prices.

GLASGOW.

Business was quieter in the past week, and as the daily supplies exceeded the demand, price movements were generally in a downward direction. In the cut flower market considerable irregularity was reflected in the values obtained by different salesmen. Thus, while one firm obtained from 2/6 to 3/6 for 6's of special pink and white Chrysanthemums, other varieties were sold by another firm as follow:—Heston White, 6d. to 9d.; Favourite, special, 1/6 to 1/9; medium, 8d. to 10d.; Winter Cheer and Baldock's Crimson, 1/- to 1/3; Golden Sunset, 1/- to 1/6; and Wilcox, 1/3. Daffodils are arriving more freely, and Golden Spurs made from 9d. to 1/6. Tulips maintained former averages, Thomas Moore being worth 1/- to 1/3; Couronne d'Or, 2/-; Prince of Austria, 1/6 to 1/9; Murillo, 10d. to 1/6; W. Copland, 1/- to 1/6; Yellow, 9d. to 1/-; and White, 10d. to 1/- for 6's. Prices of Carnations were steady at 4/- to 6/-. Mimosa realised 4/- to 7/- per pad. Narcissi, large, 4/- to 4/6 per dozen; medium, 2/- to 3/-. Lily-of-the-Valley, 2/- to 2/6; white Hyacinths, 8d. to 1/- for 3's; blue and pink, 10d. to 1/2; Lilium longiflorum (Harrissii), 5/- to 9/-; short, 3/-; and Richardias, 8/- to 10/-. Parma Violets were offered from 2/- to 3/- per bunch, and small French Violets from 1/6 to 3/- per dozen. Iris averaged 2/- per bunch.

Oranges were a cheap feature in the fruit market. Valencia 360's and 504's were purchased at 7/- to 9/- per case; 300's, 7/- to 11/-; 420's, 12/- to 18/-; 714's, 14/- to 18/-; Murcia, 360's, 9/- to 10/6; 300's, 10/- to 14/-; Mandarins declined to 9d. per box. Murcia Lemons, 300's, ranged from 14/6 to 18/-; Messina, 10/- to 12/-; and Grape Fruit, 21/- to 24/-. First consignments of Cape Fruit arrived in excellent condition. Peaches realised 6/- to 7/-; Clapp's Favourite Pears, 7/-; while Plums averaged about 3d. each. Almeria Grapes are a good market at 18/- to 26/-. English Gros Colmar sold at 2/- to 3/6 per lb; Scotch at 2/- to 3/-; and Belgrade at 1/9 to 2/-. American Apples experienced a slow sale, and prices are in favour of buyers. Winesap ruled from 9/- to 13/6 per case; Delicious, 11/- to 15/-; Oregon Newtown, 12/- to 18/-; Spitzbergen, 10/- to 13/-; Jonathan, 9/- to 13/-; Winter Banana, 10/6; Rome Beauty, 9/- to 12/-; Virginian Winesap, 25/- to 31/- per barrel; Ben Davis, 15/- to 20/-; Gano, 16/- to 19/-; York Imperial, 23/- to 29/-; Canadian Kings, 27/- to 31/-; Baldwin, 18/- to 20/-; Spy, 23/- to 27/-; and Greening, 27/- to 31/-. Prices for Pears were steady, Oregon, Doyenné du Comice sold at 15/- to 20/-; Californian Winter Nelis at 15/6 to 17/6; Oregon at 16/- to 20/-; and Washington, at 8/- to 12/-. Honey realised 1/6 per section.

In the vegetable section, Artichokes averaged 4/- per dozen; Endive and Radish, 2/-; Cauliflower, 8/- to 9/-; Lettuces, 2/6 per crate; French Beans, 1/9 to 2/6; Carrots, 6/- per bag; and Mushrooms, 1/6 per lb.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 39.5

ACTUAL TEMPERATURE—

The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, January 27, 10 a.m. Bar. 28.5. Temp. 52°. Weather, Showery.

On Seedsmen's and Nurserymen's Catalogues.

WITH the present spell of unfavourable weather open air gardening ceases to have that unlimited scope which makes it at more congenial times both an inspiration to, and the despair of, the enthusiastic gardener. Where so much is to do the inexperienced might be excused for thinking that it matters little in what order the pieces of work are done. They are apt to stand not upon the order of their doing, but time shows them the unwisdom of precipitancy and presently they learn that the closest secret of good gardening is that of all administrative work, the doing of things in judiciously appraised order. But just now, beyond clearing the snow and renovating paths, getting potting shed and tool house in trim and tools sharp, the routine work of the outdoor garden must, perforce, be suspended. Even with respect to planning new developments, the moment is not propitious; that is work which should have been done long since. Yet one thing there is which will repay the gardener and fill profitably any enforced leisure which may be upon his hands, and that is a more than usually careful study of the catalogues which the nurserymen and seedsmen are now lavishing upon him. It will well repay him to study them with attention. They show old favourites in attractive guise and, what is better, present new subjects whose pictures are so lovely as to tempt him from his established allegiances. In gardening it is always well to be a little reckless; to cultivate in moderation the Athenian virtue of ever seeking after some new thing. How far the temptation of novelty may be allowed to overpower our garden conservatism must, of course, be left to individual judgment. But surely in some respects we might show a little more accessibility to change. How many small gardens, for example, are adequately supplied with those vegetables, and particularly stem vegetables which, when grown, do so much to relieve the monotony of winter dietaries! So also is it with herbs. The disuse of simples has thrown many of them out of favour, but a garden which has not its corner or corners stocked with herbs must surely lack savour. Of more particular interest than seeking to make good such deficiencies as these is the search through the catalogues for new plants. There are the lists of new varieties to be scanned, lest perchance they may contain some novelty which promises better than the old, and no less intriguing is to discover that well stocked though the garden may be there is still room for well-proved and lovely garden plants which, as it happens, have somehow year after year been omitted from it. With respect to no plants does this omission occur more often than with bulbs. Those, for example, which have odd planting times are apt to be overlooked year after year, so that each year the gardener who neglects his time-table of planting deplores the lack of breadths of Cyclamen, of autumn Crocus and even of some among the very easily grown Lilies. It is true that he is reminded in these pages when the time comes to plant these things; but at that time he is full of garden work and engagements and so the moment slips by. Now is the time when this sort of planning may be remedied. The catalogues are portrait galleries of all these neglected beauties and those which are not portrayed are vividly described. The portraits, it may be, sometimes flatter and the descriptions may suffer from enthusiasm, but in the good catalogues—and they are many—this is but a sign of grace and not a snare; for truly it may be said of flowers what a wise and kind old man once said reprovingly to a rude youth who spoke disparagingly of women "they are all nice, bless 'em." The catalogues which stand in several ranks before us are for all kinds of garden lovers. There is the curt list for the very knowledgable—those who know what they want. There is the descriptive catalogue which adds honied words to the plant; words which both help and beguile; and there are the copiously illustrated catalogues which, by the beauty of their illustrations, allure to brighter worlds and lead the way. Not the least in interest of them all are those glum old catalogues of other days in which is modestly announced the arrival of this or that new plant. These have made garden-history and by the same token there is little doubt but those now being issued for the current year will include announcements which in time will have importance in garden history. Therefore it is well, even when they have supplied present needs and ministered to immediate requirements, that these monuments of nurserymen's and seedsmen's enterprise should not be too soon thrown away, but kept at all events until the accumulated harvests make too imperious demands upon store room. In the meantime, whilst the garden is waterlogged and uninviting, we can see reflected in the catalogues some of the beauty which at almost every other moment of the year is resplendent in the garden itself.

Gardeners' Royal Benevolent Institution.—In the unavoidable absence of Mr. Leonard Sutton, Mr. A. J. Wood presided at the annual meeting of the Charity, held at Simpson's, 101, Strand, on Tuesday, the 26th inst., at 3 p.m. There was a good attendance of supporters, and we hope to report the proceedings in our next issue. No fewer than fifty-one candidates came forward for the benefits the Institution offers to aged or infirm gardeners, or their widows, and of this number only twenty could be elected, according to the voting list circulated to subscribers; as, however, two annuitants had died since the list was printed, it was agreed to elect twenty-two candidates. Those who were successful, with the votes recorded in their favour, were as follows:—Mr. Frederick C. Bailey, Weybridge, 5323; Mr. James Cornford, Westgate-on-Sea, 4716; Mr. Henry W. Pitcher, Buckingham, 4305; Mr. Charles Canning, Betley, near Crewe, 4150; Mr. George D. White, Andover, 4098; Mrs. Eliza J. Dunn, Windsor, 3866; Mr. Frederick Styles, Worcester, 3512; Mr. Charles Seden, Peterborough, 3494; Mrs. Elizabeth Murray, Newcastle, 3350; Mr. John Thoms, Park Walk, S.W., 3273; Mr. David Betts, Exeter, 3183; Mr. John Moore, Upper Clatford, 3129; Mr. Albert Polley, Itchen Abbas, 3128; Mr. Edmund Potter, Wokingham, 2982; Mr. John Ayres, Bristol, 2977; Mr. Samuel S. Shaw, Royston, 2937; Mrs. Mary J. Towill, Bristol, 2906; Mrs. Mary Rogers, Camberley, 2864; Mr. Wm. Maskell, Hemel Hempstead, 2679; Mrs. Sarah E. Preece, High Barnet, 2677; Mrs. Eliza Carter, Ewell, 2661; and Mrs. Rhoda J. Sparkes, Horsham, 2638.

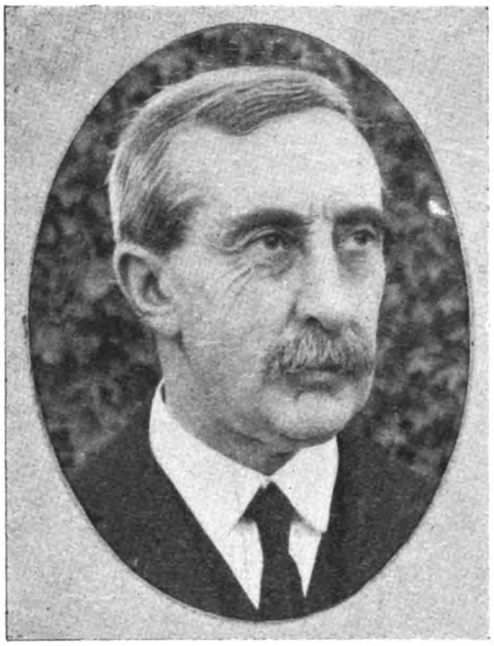
Prizes for Public Sports Grounds.—The Playground Recreation Society of America is offering special prizes to public sports grounds for progress in attractiveness made from the beginning of January until November next. The competition will be divided into three population groups, in each of which one $500 and ten $50 prizes will be awarded by the Harmen Foundation. Each of the thirty-three winning cities will also receive $50 worth of nursery stock. According to *The American Florist*, from which we glean this information, on January 6 a total of 182 cities in the United States and Canada had entered 312 playing fields in the contest.

Forcing Lettuces in the U.S.A.—The Lettuce ranks as one of the most important vegetable crops in the U.S.A. and as a vegetable forcing crop stands foremost: commercial greenhouse establishments in the United States give more space to Lettuces all the year round than to any other crop. It is estimated that the value of the Lettuce crop in 1919 was more than $8,000,000. Like our own commercial growers, American market growers use large quantities of stable manure for Lettuces, and as this material, especially in glasshouses, tends to cause sourness in the soil, the practice of applying lime to counteract the acidity is very common in that country. With a view to investigating the effect of acid soils on the crop Mr. J. W. Crist of the Agricultural Experiment Station, Michigan, conducted several experiments and comes to the conclusion that, at least under some conditions, the Lettuce is an acid tolerant plant; he observes that ordinary and often unusually high soil acidity is not detrimental to its growth. He found that the crops succeed best in a medium that is distinctly acid in reaction when the necessary plant foods are present in proper quantities and proportions. That practices differ in the United States as well as here is shown by the fact that some growers there never use lime for Lettuces whilst others apply it each year in amounts varying from 500—4,000 lbs. to the acre. The variety principally grown in U.S.A. is Grand Rapids, said to have been originated by Mr. Eugene Davis, Grand Rapids, Michigan. In the trial of Lettuces under glass conducted by the Royal Horticultural Society at Wisley, in 1924-25 this variety apparently was not included, and if it was it did not receive an award. Commenting on the trial conducted in 1923-24, the late Mr. S. B. Dicks stated (*Gard. Chron.*, Vol. LXXIV., p. 148), that the old Stansted Park variety was an easy first; in size, appearance and quality it could not be excelled. This is a Cabbage variety; the best of the Cos sorts was Hardy Green Hammersmith. Mr. Paul Aquatias, whose knowledge of the intensive cultivation of vegetables under glass entitles his opinion to the highest respect states that the best variety of Cabbage Lettuce to supply salading from January until the end of April, is the black-seeded Little Gott. Gotte a Graine Noire from Messrs. Vilmorin-Andrieux and Co., received a First Class Certificate in the Wisley trial, 1924-25.

Shrewsbury Castle presented to the Town by the local Horticultural Society.—The historical castle of Shrewsbury has been purchased for the town out of the profits of the Shrewsbury Floral Fête and will be used as a council chamber. A portion of the castle dates from Norman times, but the main part of the building was erected during the time of Edward I. Until it was purchased for the town it was in the ownership of Lord Barnard, who presided at the opening ceremony. The Mayor of Shrewsbury stated that the fortress was built to keep out the Welsh, but in the future it would bring them to Shrewsbury, for it would be used as a meeting place for Welsh organisations.

Proposed International Conference on Flower and Fruit Sterility.—There have been held already under the auspices of The Horticultural Society of New York two important conferences on matters of vital interest to horticulture. One conference in 1902 was on "Plant Breeding and Hybridisation" and one in 1907 was on "Plant Hardiness and Acclimatisation." For some time past the officers of the Society have had in mind the holding of another International Conference on some subject of timely significance to the progress of horticulture. After careful consideration the Council has decided that the subject of this conference be on "Flower and Fruit Sterility." A conference committee consisting of Dr. N. L. Britton, chairman; Mr. Frederick R. Newbold, treasurer; and Mr. A. B. Stout, secretary, was appointed; the organisation of advisory committees was authorised, and a sum of money appropriated for the expenses of the conference and for the publication of its proceedings. The conference will consider the phenomena of sterility and fertility in fruit and seed production with special reference to (a) the breeding of floricultural plants, (b) problems of fruit growing and seed production in horticultural and agricultural crops, and (c) the botanical and genetical aspects of sterility and fertility. A three-day conference is proposed, with one day devoted to the interest of floriculture, one to the problems of fruit growing, and one to the more purely scientific aspects of the subject. There will be invitation papers of the symposium type, with shorter and more special contributions as offered. It is planned to have invitation papers presented especially by several noted horticulturists botanists, and geneticists from Europe. An international Conference on Plant Sciences is to be held at Ithaca, N.Y., in 1926, which will be attended by horticulturists, geneticists, plant physiologists and others who will also be interested in the work of the Conference on flower and fruit sterility. For this reason it has been decided to hold the latter conference in New York City during the week of August 9 to 16, 1926. This will immediately precede the Ithaca Conference, the sessions of which are from August 16 to 23. The co-operation of all who are interested in this conference is requested. The Committee is now ready to receive titles of papers and an early report from those who propose to attend and particularly from those who wish to present papers is requested. Further particulars may be obtained from Mr. A. B. Stout, Secretary, Conference Committee, 598, Madison Avenue. N.Y. City, U.S.A.

Mr. Donald McKelvie.—It affords us great pleasure to publish the portrait of the best-known modern raiser of Potatos, Mr. Donald McKelvie, of Lamlash, whose productions have been referred to on many occasions in our columns. Although he did not commence Potato-raising until 1907, Mr. McKelvie has been eminently successful. The receipt of several packets of seeds from Mr. F. W. Keay of Wolverhampton excited his interest, and from these seeds he raised Arran Chief and Ally. The pollen parent was Flourball, and this variety Mr. McKelvie has used with great effect in subsequent crossings. Arran Comrade, Arran Rose, and Arran Victory followed in later years, the last being introduced to commerce in 1918. Perhaps Mr. McKelvie's greatest achievement was the raising of Arran Consul (Flourball × President), which was awarded the Lord Derby Gold Medal at the Ormskirk Trials in 1925 (see Fig. 46, p. 87). Indications of the great value attaching to Mr. McKelvie's additions to one of our principal food crops may be gathered from the fact that he was awarded the Snell Medal by the Council of the National Institute of Agricultural Botany in 1924, and in November last he was entertained to a complimentary dinner at Brodick by the Arran Farmers' Society, when he was presented with his portrait in oils painted by Mr. Grieffenhagen.



MR. DONALD MCKELVIE.

Denham Demonstration Garden.—The Denham Demonstration Station was established by the Middlesex Education Committee in 1924 as an experimental station and trial ground. The station consists of about ten acres of land at Rusholt Farm, Buckinghamshire, the estate recently acquired by the Middlesex County Council for the purpose of small holdings. It is situated in the centre of the estate, about one-and-a-half miles from the town of Uxbridge. The soil consists of a medium loam overlying gravel. The ground is laid out in plots of approximately half-an-acre, and during 1925, amongst others, trials were conducted of Strawberries; Apples and Plums intercropped with various vegetables; and Pears intercropped with Peas. In manurial trials of Currants, the following mixtures produced the best results:—(1) superphosphate of lime, 4 lb.; sulphate of potash, 1½ lb.; sulphate of ammonia, 1½ lb.; and kainit, 1 lb.; (2) sulphate of ammonia, 1½ lb.; superphosphate, 2½ lb. sulphate of potash, 2 lb.; and S.B.F. (presumably steamed bone flour) 2 lb. The above mixtures were applied at the rate of half-a-pound per bush immediately after growth had commenced. A permanent plot planted with Gooseberries and Raspberries was intercropped during the past year with varieties of Broccoli. Of the latter, Michaelmas White and Autumn Protecting were of outstanding merit. The trials in 1925 also included Savoys and Brussels Sprouts and main crop Potatos. Growers in Middlesex who are interested in the report may obtain copies from Mr. B. S. Gott, Secretary to the Middlesex Education Committee, 40, Eccleston Square, S.W.1.

All Night Pay for Gardeners.—We learn that an interesting and humorous discovery has been made in Paris in connection with the gardeners at the Palais Bourbon and the Palace of Versailles. It appears that an arrangement was made long since to grant a special rate of pay to members of the staff attached to the Chamber of Deputies, if and when the Chamber sat during the night. As there are four gardeners attached to the staff at the Palais Bourbon and one at Versailles, these fortunate horticulturists have received extra pay on occasions when the Chamber has sat from 9 p.m. onwards, although they have not had to remain on duty. The humour is emphasised by the statement that a sitting from 9 p.m. to 1 a.m. constitutes one night—in respect of extra pay—and if it continues beyond 1 a.m., then another night's pay becomes due!

Brighton, Hove and Sussex Horticultural Society.—This progressive Society has a membership of over one thousand, no fewer than 418 new members having been added to the register during the past twelve months. During the past few years the Society has held a summer show and a Chrysanthemum show, and it has now decided to hold a spring show, which will take place this year on April 14 and 15. During the winter a series of successful meetings have been held and several gardens were visited during last summer. The total receipts for the year amounted to £1,475 7s. 7d., and the Society has a balance, including cash on deposit of about £773 11s. 2d. It is satisfactory to know that the receipts of the summer show more than equalled the expenditure, for the first time in the history of the Society.

Endemic Australian Flora.—At a recent meeting of the Royal Society of Edinburgh, presided over by Professor J. H. Ashworth, the principal communication was made by Professor A. Anstrüther Lawson, Professor of Botany in Sydney University, on "Endemism and Evolution as observed in the Australian Flora." Professor Lawson stated that the vegetation of Australia formed one of the most unique and interesting floras inhabiting the earth at the present time. This was due, in the first place, to it high percentage of endemism. Although it was a very large and rich flora, seventy per cent. of its species and about thirty per cent. of its genera were endemic. At present it was practically uncontaminated by the artificial invasion of other types of plant life. This vast flora, therefore, appeared a fruitful field for the investigation of endemism and other problems of evolution. The most obvious feature of the great continental flora was the predominance of the genus Eucalyptus. With its 300 species it stood out as the most conspicuous feature of the entire vegetation and was distributed over the whole continent, except in barren deserts. No other continental flora was so predominated by a single genus. While the Myrtaceae—which included this great genus—predominated, the Leguminosae included many more species, and its important genus ranked next to the genus Eucalyptus in predominance. The tribe Proteaceae, however, was of much greater interest, although it took third place. The most outstanding and important problem in connection with this flora was the origin of its endemism, and should it be solved, it would open the way to an understanding of the evolution of the entire flora. During the past twelve years the various endemic genera of the Proteaceae, such as Grevillea, Banksia, Hakea, Telopea, Xylomelum, Isopogon, etc., and the main endemic genera of the Myrtaceae had been investigated by the writer. On account of their wide range of form, habit, habitat and variability, and more especially because of their marked tendency to sterility, he felt justified in suspecting them to be of hybrid origin, and this line of enquiry had produced profoundly interesting results. The irregular mitoses found in many of them were eventually the same as those of the hybrid Drosera described by Rosenberg in 1904 in his classic work, and of the very many endemic types investigated, all, without exception, revealed evidence of their being hybrids. This was shown in the sterility of the pollen and the corresponding abnormality of meiosis. The conclusion drawn from this investigation was that endemism in the Australian flora had its origin in hybrid mutation in the first place from the non-endemic types. This type of hybrid mutation was directly opposed to the theory of mutation of De Vries and the Morgan School in America. Hybridisation followed by natural selection had been the main factor in the evolution of the Australian flora.

Gardeners' Royal Benevolent Institution (Worcester Auxiliary).—During the past year the Worcester and District Auxiliary of the Gardeners' Royal Benevolent Institution forwarded the sum of £105 to the parent institution. About half of this amount represents the proceeds of opening the gardens of Ynys-y-Maegwyn, Davenham and Madresfield, to the public at a small charge, and in addition to their kindness in throwing open their gardens, the names of the owners R. J. Corbett, Esq., Dyson Perrins, Esq., and the Rt. Hon. The Earl Beauchamp appear in the list of subscribers. The committee's report states that membership continues at a steady level, and although some subscribers were lost during the year, they have been replaced by new members. The hon. secretary is Mr. Percy G. White, 51, Broad Street, Worcester, and the executive committee includes most of the well-known gardeners and nurserymen in the Worcester district.

Plants of Garden Merit.—We learn from the *Journal* of the Royal Horticultural Society, vol. LI, part 1, that the award of Garden Merit was conferred on the following plants in 1925: Cotoneaster horizontalis, Ribes speciosum, Rhododendron Thomsonii, R. hippophaeoides, Primula pulverulenta, Anemone nemorosa Alleni, Primula rosea, Rosa altaica, Rosa Moyesii, R. Hugonis, Ceanothus × Gloire de Versailles and Ceanothus × Veitchianus. So far, thirty-four plants have been honoured with this award, but no mention is made of the authorities who have selected the plants. Some, such as the two Ceanothuses, Primula rosea and Rhododendron Thomsonii are old and well-known garden plants, and others such as Rosa Moyesii and Rhododendron hippophaeoides are of more recent introduction. The descriptions which accompany the plants are exceedingly interesting, and in most cases references are given to illustrations of the plants.

Eradication of Rest-harrow.—In certain districts where the Rest-harrow (Ononis) is a nuisance when it spreads among pasturage and other greensward, gardeners and farmers will be glad to learn that it may be eradicated by salting. In a communication published in the *Journal* of the Board of Agriculture, Mr. P. Murray Thomson states that in an old pasture in Cumberland this weed was eradicated by heavily salting the affected areas and repeating the dressing if any plants appeared to have been missed. All the grass in the salted area was killed, but very little Rest-harrow reappeared, and where it did, it was immediately re-salted. The bare patches were sown with suitable grass seeds in the season after salting and quickly formed a good sward.

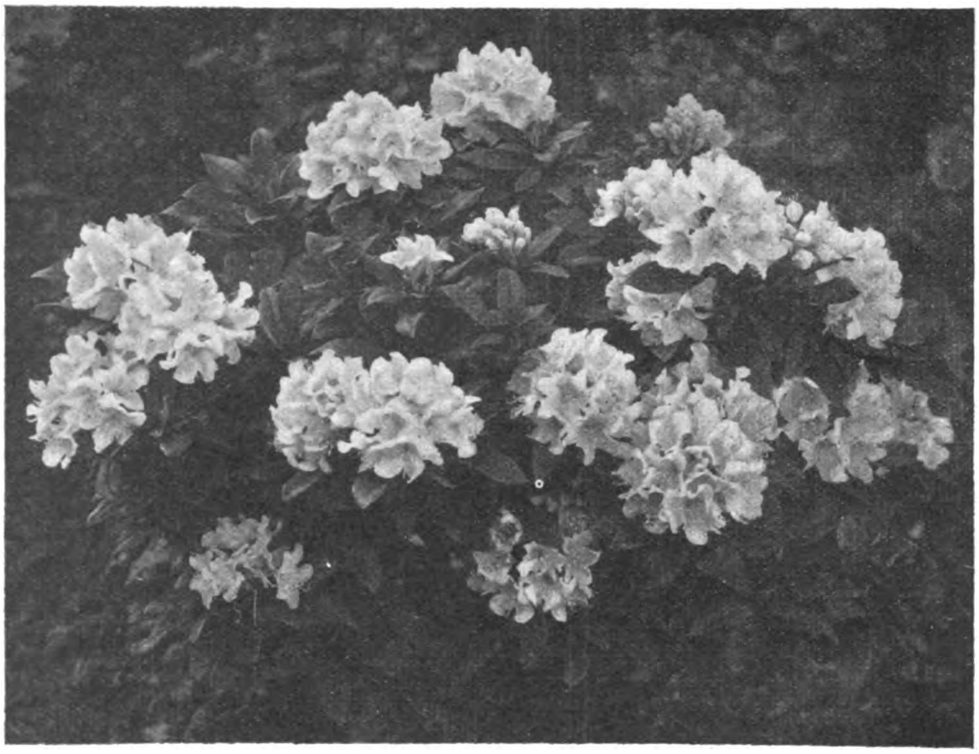


FIG. 37. RHODODENDRON SULPHUREUM.
(see p. 79).

Romsey Gardeners' Association.—The programme of this association includes a lecture on February 1, on "Apples," by Mr. Haysom; "Sweet Peas for Home and Exhibition," on March 1, by Mr. F. Castle of Chandler's Ford; and "Anemones and Tulips," on April 12, by Mr. H. Mattingly. Four outings have been arranged: on May 3 to Harefield; on May 17 to Embley Park; on June 7 to Colbury House Gardens; and on July 5 to Messrs. Sutton and Sons, Reading.

Appointments for the Ensuing Week.—Monday, February 1: National Chrysanthemum Society's Annual Meeting at Essex Hall, Essex Street, Strand: Romsey and District Gardeners' Association's meeting. Tuesday, February 2: Royal Caledonian Horticultural Society's meeting. Wednesday, February 3: Abingdon Horticultural Society's meeting. Thursday, February 4: Manchester and North of England Orchid Society's meeting. Friday, February 5: Dundee Horticultural Society's lecture; Accrington and District Chrysanthemum Society's meeting. Saturday, February 6: Blackburn Horticultural Society's meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Messrs. Henderson's, Pine-apple Place.*—Jasminum nudiflorum, in the shape of a small bush, has been blooming in the open ground here for some weeks past. It promises to be one of the most desirable of our winter-flowering shrubs. The show-house is already gay with the various spring bulbs, such as Hyacinths, Roman Narcissus, Van Thol and Tournesol Tulips, etc., intermixed, here and there, with small examples of the deliciously sweet-smelling Daphne odora rosea, Cyclamens, Chinese Primulas, and Cinerarias. These, again, are backed up by Epacrises, the Winter Heath, Linum trigynum, Camellias, Rhododendron Nobleanum, and one or two other plants. The stove contained flowering specimens of Centradenia floribunda, Pentlandia miniata, an Amaryllid or two, some Begonias, which are always gay during winter; the white variety of Poinsettia pulcherrima, and some other things; the specimen house was filled with excellent plants, neatly arranged. Eriostemon intermedium, the most handsome of the genus, was just coming into flower, in which condition it will remain for many months. Styphelia tubiflora, one of the earliest of Epacrids, was in full blossom, and we observed a spike or two of the curious hybrid Veronica Andersoni coming into beauty. Double Chinese Primulas, the red and fringed white, were in bloom here. These were in deep pans, and were specimens of considerable size. The way in which they are cultivated here is to strike the cuttings, in spring; keep them growing slowly till August when they are more liberally shifted and more, generously treated, and they blossom about Christmas. After they have done flowering they are placed near the glass, and kept rather dry and cool, so as to give them a season of rest until the beginning of August, when they are repotted, their branches spread out and pegged down, and under this kind of management they blossom much better the second year than the first, beginning about Christmas and continuing on till May. The old plants are thrown away after they have flowered, the second year, and their places are supplied by one-year-old plants. The variety of Corraea called "Brilliant" was in blossom here, as was also a small plant of the deep purple-coloured Hovea pungens, a beautiful New Holland shrub, but difficult to manage. We likewise remarked in this house some "tree" Carnations, whose perpetual habit of blooming must render them favourites. After flowering they will be shortened back, summered in the open ground, and then brought into the greenhouse to blossom again next winter. It is stated that Cryptomeria japonica, though hardy, becomes brown in winter, when to be effective it should be green. A specimen in this nursery exhibited this defect. It was growing close to the edge of a small pond. *Gard. Chron. February* 1, 1851.

The Week's Work.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Phaio-calanthe.—This Orchid is a garden hybrid between Phaius and Calanthe. The plant does not need such a decided season of rest as Calanthe, but so soon as the flowering period is past the roots should be afforded just sufficient water to maintain the pseudo-bulbs in a plump condition. These Orchids are subject to spot disease of the foliage, which may ofttimes be obviated by placing the plants in a dry position in the Cattleya house, where they will be well supplied with fresh air, without being subject to cold draughts. After a short rest the plants will begin to grow afresh, when any necessary re-potting may be attended to. This need not be done each year if the compost is in good condition, and there is sufficient room in the pot for another season's growth.

Laelia pumila.—This useful, dwarf-growing Laelia has recently passed out of flower, and so soon as fresh root action is observed, the plants may be re-potted or re-surfaced. Shallow pans with wire handles attached for suspending the plants are suitable receptacles ; they should be well-drained and only a thin layer of compost need be used, as when the plant is well-rooted in the soil it needs a liberal supply of water all through its season of active growth. It is important that the water passes away quickly The plants grow best in an intermediate temperature.

Platiclinis.—The pretty Platiclinis uncata is sending up its flower spikes from the half-grown shoots. Having to support its flowers and make growth at the same time, a liberal supply of water at the roots will be needed all through the period of growth. The graceful spring blooming P. glumacea is now sending out new shoots from the base of the last made pseudo-bulbs. This plant should be grown in a position near to the roof-glass in the intermediate house. Any necessary re-potting is best done soon after the flowers have faded, using shallow Orchid pans that can be suspended. P. filiformis is now at rest ; this plant flowers during the summer. Members of the genus Platiclinis are very subject to attacks of red spider, therefore the leaves should be sponged frequently with a solution of soft soap and tepid water.

FRUITS UNDER GLASS.

By T. PATEMAN, Gardener to SIR CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Pot Vines.—Vines in pots that were started into growth last month are showing signs of active growth, and at this stage extra care is needed in watering the roots and ventilating the house. Guard against cold draughts, and use tepid water to keep the roots moist. Pay careful attention to disbudding and tying the shoots, retaining only the strongest and best placed laterals. The night temperature should range from 55° to 60° until the bunches are visible, but the grower must be guided by outside conditions. Observe the lower temperature in cold weather rather than overheat the water-pipes, for this would cause a dry atmosphere which would favour the spread of red spider. A humid atmosphere is the best preventive of this pest, and atmospheric moisture may be promoted by damping the floors and walls, and on bright days syringing the vines overhead with soft tepid water, but so soon as the vines come into flower discontinue syringing, damping the available bare places only. Raise the night temperature to 60° at that stage.

Successional Vines.—To provide a succession of Grapes, a vinery that has been thoroughly cleansed, and the border put in order may now be closed. If the outside conditions are cold, use only sufficient fire-heat to maintain a night temperature of 45° to 50°, allowing the temperature to rise slightly during the day, but air should not be admitted unless the temperature rises over 65° with solar heat. If the vines are young the rods will break more evenly if they are bent over or tied in a horizontal position. On bright days the vines may be sprayed with tepid water early in the afternoons, but this must be governed by the outside conditions, and some judgment is required as to what amount of atmospheric moisture should be promoted. It is always wise during the early months of the year to syringe sufficiently early in the day to ensure the vines becoming dry again before nightfall. Examine the borders carefully to see if moisture is necessary. The borders should never be allowed to become unduly dry, but on the other hand, when the vines are not in active growth water should only be supplied in sufficient quantity to meet the requirements of the roots, or the borders may soon become waterlogged and stagnant.

Pot Figs.—Where fermenting material was used for the plunging of the pots, this should be examined, and if the heat has declined, it should be renewed. The warmth from the dung will soften the effects of fire-heat and create a more humid atmosphere. Keep the night temperature at 55°, with a rise of 10° during the day.

THE KITCHEN GARDEN.

By F. STREETER, Gardener to MAJOR ALBERT PAM, Wormley Bury, Broxbourne.

Early Potatos.—Every effort should be made to produce a supply of new Potatos as early as possible. If the tubers for forcing were selected last autumn and placed singly in shallow trays, they will be in good condition for planting. I prefer herring boxes, as recommended by Mr. Edwin Beckett, to pots for planting ; they are more easily handled and may be conveniently moved into houses of the correct temperature. I find that one hundred boxes is a good number to start with, but this will depend on the requirements of the establishment. Place a few leaves on the bottom of the box to serve as drainage material, and half-fill the box with a compost of light, turfy loam and leaf-soil. Place the tubers very lightly in the boxes, using two sets, disbudded to the strongest shoot, in each box. Water the soil with tepid water about the second day after planting,and place the boxes in a fruit house that has just been started. They may be stood under the stage, if room is scarce, until the growths appear. All sets should by this date have been selected for planting out-of-doors and placed singly in trays for sprouting. Keep them in a frost-proof light shed or room.

Rhubarb.—Where a Mushroom house is available it is an excellent place in which to force Rhubarb. Select the warmer end of the house for the first batch, placing the other batches in rotation along the floor. Scatter some litter thinly on the ground on which to place the crowns, then cover the roots with sufficient soil to give them a good start. Select the finest clumps for this purpose, that have been growing undisturbed for at least three years. When damping the floors of the house, spray over the crowns gently with tepid water, and should the water pipes enter the house at the end where the Rhubarb is placed, see that the latter is never allowed to become dry.

PLANTS UNDER GLASS.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

Rhodochiton volubile.—This beautiful greenhouse climber should be more generally grown for greenhouse decoration, especially as it is easily raised from seeds, and may be treated as an annual. When planted out, it is seen at its finest in its second year. Seeds are best sown any time during January in a warm house, and when large enough, the seedlings should be placed singly in small pots, potting them on as they require more root-room, until they are in six-inch or seven-inch pots, in which they will flower. In their younger condition they should be kept tied to neat stakes until they are in their flowering pots, when they may be placed in the greenhouse, and the shoots trained up wires or string under the roof-glass. This plant thrives in any good potting compost.

Gesnera cardinalis.—Where there is a stock of this beautiful plant, the dry tubers should be started in the same way as Gloxinias, these plants succeeding under similar treatment. If it is desired to raise a stock of the Gesnera it may be easily propagated from seeds sown at this date in the same manner as advised for Gloxinias. The successful flowering of the plant in its first year from seed is, however, somewhat uncertain. This beautiful plant, when in flower, may be used for the decoration of the greenhouse.

Isoloma hirsutum.—This is a most useful plant for either the intermediate house or greenhouse, and by rooting successional batches it may be had in flower more or less all the year round. In its younger stages, this plant is very useful for furnishing the benches ; afterwards it may be transferred to eight-inch pots to make large specimens for standing in the beds. Isoloma hirsutum is easily increased by means of cuttings, or the scaly rhizomes ; President Chandon is a beautiful hybrid Isoloma which succeeds under the same intermediate-house treatment during its growing period.

Carnations.—Continue to take cuttings until the required stock of plants has been propagated, Care should be taken to select the right kind of cuttings from healthy plants. The cuttings should be about three inches to four inches long, and they should not be obtained from near the base of the plants, not from the top : the right type of cutting is usually found about the middle of the plant. Where a large stock of Carnations is required, it is usual to insert the cuttings in a special bed of sand, but in the ordinary way it is just a well to insert the cuttings in three-inch or five-inch pots ; or pans may be used. A little loam should be mixed with the sand, as cuttings taken from sand beds require very careful handling when they are first potted.

Solanum capsicastrum.—This berried plant is valued during the autumn for its bright effect, and a stock of it may be raised at this time either from seeds or cuttings. The young plants should be pinched several times to promote a bushy habit. The plants should be potted on as they require it. During the summer they should be stood out-doors in an open, sunny situation.

HARDY FRUIT GARDEN.

By W. AUTON, Gardener to VISCOUNT ELVEDEN, Pyrford Court, Woking, Surrey.

Wall Trees.—The pruning and training of fruit trees trained against walls should be proceeded with wherever possible, when the work can be done. Certain varieties of dessert Pears and Plums are well worth the protection of a wall, and produce fruits of excellent quality in such positions, when they would be less successful in open situations. Pears may be fan-trained or grown as cordons, but the latter system is not desirable for Plums as they resent the restriction entailed. If summer pruning has been done judiciously, very little winter pruning will be necessary, but it may be advisable to thin the spurs where they are too numerous. It is good policy to remove all ties every year, when not only the trees but also the surface of the wall may be thoroughly cleansed before making the shoots secure again. Where wires are not provided and the branches are fastened to the wall by means of shreds, the latter should be destroyed and new ones substituted, as they almost invariably harbour the eggs of various insect pests.

Orchard Trees.—Where orchards of standard trees are established and the whole area has been allowed to become covered with grass, it is advisable to keep the surface cultivated for a space of three feet around the stems of the trees. That many orchards exist where this routine is not practised cannot be gainsaid, and when the trees have reached maturity it is perhaps not so essential, but for trees which still have much of their growth to make it has decided advantages, as it aerates the soil, facilitates feeding and encourages the formation of fibrous roots. In orchards where planting is of comparatively recent date, all stakes and ties should be examined with the object of replacing any faulty stakes and loosening the ties, to allow for the swelling of the stems during the current season of growth. Rabbits frequently do serious harm to orchard trees by barking the stems, and the evil becomes more acute when snow covers the ground. Wire netting placed around the stems is a good protecting agent, but unless this is of substantial width the rabbits often bark the stems above the wire, especially after heavy snow storms, when the frozen snow gives them considerable advantage in reach. Where damage is being done in spite of wiring, the expedient of painting the stems with something disagreeable to the rabbits should be resorted to. This may consist of a mixture of slaked lime, cow-dung, grease and Quassia extract, reducing the whole to the consistency of thick paint. A close watch should be kept on grease bands on all trees, and when necessary, the sticky material should be renewed, or the female moths ascending the trunks will not be captured.

Bush Fruits.—If sufficient decayed manure is available, there is nothing better that can be used as a mulch in the bush-fruit plantation, and if the surface is clean, the material may be applied when weather conditions make planting impossible. If such material is not available, a liberal dressing of bone-meal may be applied and lightly forked into the surface soil.

THE FLOWER GARDEN.

By F. C. Puddle, Gardener to Lord Aberconway,
Bodnant, Taly-Cafn, North Wales.

Antirrhinums.—The Antirrhinum is one of the most useful plants for garden decoration, and it is very accommodating in that the seeds may be sown in spring and the plant treated as an annual, or sown in autumn and treated as a biennial, or propagated from cuttings as a perennial. Antirrhinums in various colours, judiciously blended, are very beautiful in borders or beds, and some very pretty effects may be obtained by associating them with other annuals, as for instance:—pale yellow Antirrhinums and Blue Gem Nemesias, also crimson Antirrhinums and orange Nemesias.

The Rock Garden.—Although the majority of alpines are still dormant, the rock garden should be attended to periodically, and any plants which have been lifted by the action of frost made firm again. Leaves which have accumulated in odd corners should be removed, as they afford harbourage for slugs. A little judicious pruning of the shrubs may be necessary and this work should be done forthwith. It is important that they should not encroach on the alpines, but care should be taken not to give them a clipped appearance, or to prune them out of their natural shape. Some of the earlier-growing alpines in frames are commencing to grow, but their watering should still be done with great care, and in damp periods it will generally be found sufficient to keep the ashes in which the pots are plunged, moist. The frames should be freely ventilated at all times, and the atmosphere kept as dry as possible.

Sweet Peas.—The main sowing of Sweet Peas may now be made. When a moderate supply of plants is required, the usual practice of sowing in pots may be followed, but where larger quantities are wanted for garden decoration, and for cutting, the method of sowing the seeds in turves has much to commend it. A cold frame, and preferably one containing an old hot-bed, so that the turves may be brought close to the glass, should be chosen, and freshly-cut turves twelve inches square and not less than three inches thick, secured. The turves should be divided into three-inch cubes, and these packed in straight lines across the frame until all the available space is filled. The frame is then ready for sowing. Germination may be accelerated by placing the seeds in water for about eighteen hours before sowing them. A convenient method of doing this is to place a number of small pots, each with a piece of paper fixed firmly in the bottom, in a shallow tank: water to the depth of one inch should then be poured in and the seeds placed in the pots and duly labelled. The seeds may be sown one or two in each cube, according to the space available, at a depth of half-an-inch. The surface should then be covered with a thin coating of fine soil, and a line of lime and soot placed around the frame as a deterrent to slugs. The frame should be kept close until the seeds germinate, but afterwards it should be ventilated freely. It will be found an advantage to decide on the scheme of planting beforehand, so that the seeds may be sown in the same order, which will facilitate their removal at planting time.

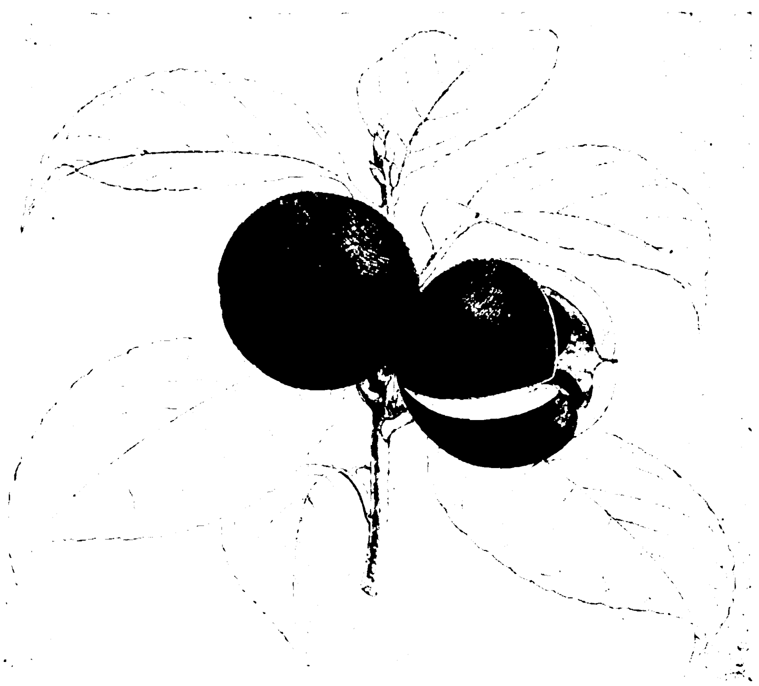

FIG. 38.—CAMELLIA FRUITS.

(see p. 79).

FOR NORTHERN GARDENERS.

By A. T. Harrison, Gardener to the Marquis of Ailsa, Culzean Castle, Maybole, Ayrshire.

Seed Sowing.—Many seeds may now be sown under glass, and if early crops are desirable, a box or two of the various Brassicas should be sown, including early and late Cauliflowers, Brussels Sprouts, Cabbages, both green and red, and Lettuces. Leeks and Celery, if required for August and September shows, should now be raised from seeds sown in heat and grown on steadily under favourable conditions until they are ready to plant out in well-prepared trenches. Prick out earlier-sown Tomatos when they are large enough to handle, and sow again for mid-season use. Where Cucumbers and Melons are required early, the seeds should be sown in a fairly high temperature. These early crops should only be attempted where ample provision exists for ensuring the requisite warm temperature being maintained during cold spells.

Vineries.—Where vines are grown entirely without fire-heat, the houses should now be closed, and if the border is at all dry it should be soaked with tepid water. On warm, sunny days, damp the house, but do not open the ventilators; even if the nights are very cold the sun's warmth that is retained will be sufficient to keep out frost. This treatment should be continued for a month or six weeks, when the buds will be bursting, and by the end of March the vines should be showing their first leaves. At this stage the top ventilators should be opened on sunny days. Continue damping and syringing to ensure a moist atmosphere, and close the ventilators as early as possible after midday to raise the temperature again. Some growers are of the opinion that Grapes cannot be produced in this country without a heavy expenditure on coal, but the results obtained here during the past six seasons have been excellent, and unless Grapes are required early, that is, before the end of August, there should be no difficulty in growing and finishing Grapes to perfection. This cool treatment is not suited to all varieties; those which have responded best to this cool treatment include Black Hamburgh, Gros Maroc, Directeur Tisserand, Alicante and Mrs. Pince.

Re-potting.—So soon as the flowering period is past is the most suitable time to divide and re-pot Cypripedium insigne and its varieties. These valuable winter-flowering Orchids produce such a wealth of useful and lasting cut flowers during winter that if an increase in their numbers is desirable they may now be turned out of their receptacles and divided to almost any extent. Select healthy portions and re-pot them in a compost of turfy loam, rough leaf-mould, or even rough leaves with the addition of chopped Sphagnum-moss. This, coupled with the provision of ample drainage, will suffice for the plants' needs, and while they do not require this treatment annually, it is as well to re-pot a portion of the stock each year, and so ensure flowers of high quality.

ORCHID NOTES AND GLEANINGS.

CYMBIDIUM NIVEUM.

A FLOWER of this pretty hybrid, raised between C. eburneum and C. erythrostylum, is sent by Frederick J. Hanbury, Esq., F.L.S., Brockhurst, East Grinstead. It is intermediate between the two parents, and shows well the elegant habit of C. erythrostylum.

The flower, which has nearly equal sepals and petals, is silver white with the lip intensely spotted with rose colour.

The flowers of C. erythrostylum crosses are not so large as those with C. insigne, but the habit of the spikes and the elegant arrangement of the foliage render the plants specially attractive.

CYPRIPEDIUMS FROM ASHTON WOLD.

THE Hon. Mrs. N. C. Rothschild, Ashton Wold, Oundle (gr. Mr. C. Wright) has forwarded a good selection of hybrid Cypripediums raised at Ashton Wold, all of which are specially well-grown, and some of them new crosses.

Among the known crosses, flowers of C. Hera-Beeckmannii, C. Aure-Euryades and C. Leeanum crosses are very fine, the inflorescences having in some cases two flowers each.

C. The Duchess, Ashton Wold variety (aureum Hyeanum × insigne Chantinii) is a model flower of perfect shape; the large, round, dorsal sepal has heavy, claret-coloured spotting on the lower half and is pure white above. C. Astron (Beeckmannii × Stevensii), a good variety, was raised at Ashton Wold some years ago and has been again used for crossing.

C. Oriana (The Duchess × Fairrieanum) is a worthy addition to its class, showing much of the rich rose-purple spotting on the white dorsal sepal as in the best form of C. insigne Chantinii. The petals are sap-green with numerous spots and lines of chocolate-purple colour; the shining lip is dark chocolate-purple.

C. Memo (Astron × The Duchess) is a very large and finely-shaped flower with pure white dorsal sepal that has a small greenish base, and on the basal half spotted lines of claret-purple, which are darkest in the middle. The broad petals are honey-yellow, closely set with dark purple lines and spotting. The large lip is faced with purplish-brown, the side lobes and staminode being yellow.

DENDROBIUM LODDIGESII.

REFERENCE to the fine specimens of Maxillaria venusta, shown by Mr. J. Cypher (see January 2, p. 6), and subsequently even larger plants by Messrs. J. Cypher and Son, suggests calling attention to the grand plants of Dendrobium Loddigesii, with hundreds of flowers, which were often some of the most admired specimens in collections, yet in recent years, this Orchid has been neglected by growers. It stands alone in the genus Dendrobium, and should be easily recognisable, yet it has been the subject of more confusion and erroneous names than most species. It was figured in Loddiges' *Botanical Cabinet* as D. pulchellum in 1833, and under that name it was known until the late Mr. R. A. Rolfe, in an interesting article in *Gard. Chron.*, August 6, 1887, p. 155, gave a complete history of the plant and conferred on it the name of D. Loddigesii.

D. Loddigesii is a Chinese species of densely tufted habit, having numerous, closely-arranged, leafy pseudo-bulbs, three or four inches in length, and bearing singly on short stems showy flowers, one-and-a-half inch across. The sepals and petals are light mauve on a white ground; the lip is broad and orbicular in outline, pale mauve with a large orange-yellow disc.

The best specimens have been grown in shallow Teak wood baskets suspended in a cool intermediate house. This Orchid was often grown in a warm greenhouse, fruit house or conservatory in old gardens, and such plants remained in good health, while specimens in a very warm house failed. It is the Dendrobium Seidelianum of Reichenbach, but D. Loddigesii has priority. *J. O'B.*

NEW HYBRID ORCHIDS.

(*Continued from December 26, p. 498*).

Name.	Parentage.	Exhibitor.
Brasso-Cattleya Cyclops	B.-C. Hercules × C. Trianae	Sanders.
Brasso-Cattleya Enodoe	B.-C. Digbyano-Mossiae var. Queen Alexandra × C. Snow Queen.	Sanders.
Brasso-Cattleya Estrella	C. Queen Bess × B.-C. Vilmoriniana	M. Theodore Pauwels.
Brasso-Cattleya Mrs. Robert Paterson	C. Clotho × B.-C. Cliftonii magnifica	Black and Flory.
Brasso-Cattleya Sindoro	C. Empress Frederick × B.-C. Vilmoriniana	M. Theodore Pauwels.
Brasso-Cattleya The Provost	B.-C. Rosita × C. Peetersii	Black and Flory.

Potinara aurata	L.-L.-C. Anzac × B.-L.-C. Joan	Charlesworth and Co.
Vuylstekeara Lutetia	Vuylstekeara Brewii × Odm. luridum	Charlesworth and Co.

INDOOR PLANTS.

WINTER-FLOWERING BEGONIAS IN AMERICA.

THE large-flowered race of early Winter-flowering Begonias given to us originally by the late Mr. John Heal, and supplemented in more recent years by Messrs. Clibran, of Altrincham, is very popular in America on private estates; the plants flower, in the main, with us, a little too early for the commercial growers who want quantities of brightly-coloured flowering plants for the Christmas trade. A few florists have tried them but do not appear to have been particularly successful with them; however, they are largely grown on very many private estates. With us, the bulk are at their best at the time of the Chrysanthemum exhibitions, during the first half of November, although some will flower so late as January if not grown in too much heat. At the last exhibition of the Massachusetts Horticultural Society there were numbers of good sized groups, of extremely well grown plants, and these attracted fully as much attention as the Chrysanthemums; some of the plants were fully a yard in diameter, and all were simply smothered with blooms. All the varieties popular in England are grown here.

Of the smaller-flowered, winter-blooming Begonias, tens of thousands are grown here for the Christmas trade. Very few of B. Gloire de Lorraine are now seen, and even Glory of Cincinnati has all but disappeared to make place for Melior which is of a better habit than Cincinnati, and seems to stand the drying atmosphere of our steam-heated American homes better; although many sizes of these plants are grown, the most popular are those in six-inch and eight-inch pans.

Limited numbers only of the dark-leaved and deep pink-flowered Mrs. Petersen are seen, but moderate numbers of Gloire de Chatelaine, or improved forms of it, are sold. Both these latter, as well as the large-flowered Begonias are propagated from full-sized leaf cuttings, a method that has all but superseded the old-time stem cuttings, and appear to produce better plants. Leaves are usually put in the propagating benches in clean, sharp sand, where there is a steady bottom heat, during November and December, and, properly treated, nearly 100 per cent. will root. Later batches of cuttings are used to give smaller plants, and some stem cuttings are utilised for the very small sizes, these not being rooted until summer in the case of such varieties as Melior and Mrs. Petersen. *William N. Craig, Weymouth, Mass., U.S.A.*

FRANCOA RAMOSA.

SEEDLING stocks of this old herbaceous perennial vary considerably. Propagation by cuttings of the improved type grown in pots for cool greenhouse decoration is recommended.

Non-flowering growths, removed in autumn and inserted singly in small pots, root quickly. If wintered in a cool greenhouse the plants will be ready for transference to four-inch pots early in the year, placing them in pots six inches in diameter, in which they will flower later in the season. They require a strong, rich soil.

When established in four-inch pots, they may be removed to a frost-proof frame. As the flower-spikes develop they will require more head-room, and, after being neatly staked, the sashes may be removed, and the plants fully exposed, placing them in the show house or conservatory when the flowers expand. *Fred W. Jeffery.*

TREES AND SHRUBS.

CAMELLIAS FRUITING.

Mr. E. Scaplehorn, of Beckenham, very kindly informs us that last autumn he saw fruits on a Camellia growing out-of-doors in the gardens of Sir Francis Oppenheimer at Toys Hill, Brasted, Kent, and asks if this is not an uncommon occurrence.

While Camellias fruit very freely in many Riviera gardens, particularly in Italy, and also, with less frequency, in south-west Cornwall, it is not often that fruits are formed on bushes growing in colder districts. We remember seeing tall bushes in the Falmouth district some years ago that bore large crops of fruits which, in the early autumn, had become brightly coloured on the sunny side, and from a little distance presented the appearance of small, rosy Apples. In a note printed in *The Gardeners' Chronicle* of December 1, 1900. Mr. A. C. Bartlett remarked on the peculiarity of the striped-flowered variety. Comtesse Lavinia Maggi, bearing fruits similarly striped with red colour, whilst the fruits from an unnamed semi-double, red-flowered variety were reddened entirely on the side exposed to the sun.

During its eighty-five years of publication, *The Gardeners' Chronicle* has contained a number of references to the fruiting of the Camellia. The issue of December 27, 1873, contains a full-size illustration of a pair of fruits which had formed on a Camellia growing out-of-doors at South Lychett House, Poole, Dorset, and on January 26, 1884, we illustrated a fruiting branch of Camellia Donckelaari from Spring Grove, Bewdley. More recently, the issue of December 15, 1900, contains an illustration of a fruiting branch of a Camellia on which may be well seen a fruit dehiscing into its characteristic three capsules, whilst a similar, though smaller illustration appeared in our issue for September 11, 1915 (Fig. 38).

As Mr. Scaplehorn observes, the solitary fruits contained in each capsule have much the appearance of Barcelona Nuts. In this country seeds produced out-of-doors are often infertile, but we have records of seedlings raised for stock purposes, from fruits ripened in cool and airy conservatories. It would seem that it is the single and semi-double varieties that fruit most freely.

RHODODENDRON SULPHUREUM.

This beautiful yellow variety of Rhododendron (Fig. 37) was raised by the celebrated Mr. James Cunningham, of Comely Bank Nurseries, Edinburgh, from R. caucasicum crossed with R. arboreum album. It is one of the best of the hardy yellow Rhododendrons, producing bold trusses of sulphur-yellow coloured flowers in April or May.

R. caucasicum has yellowish-white blooms and many of the garden varieties of Rhododendron having yellow on the otherwise white corolla have R. caucasicum in their parentage. Mr. Cunningham also raised the beautiful Cunningham's White from R. caucasicum, the other parent being R. ponticum album.

WINTER-FLOWERING HEATHS.

During the first week of the New Year, it was interesting to observe several different Heaths in flower making a delightful picture in the Heath garden. The wonder is that these inexpensive plants are not more extensively grown for the decoration of the garden during winter. They thrive in most soils, except those of a very calcareous nature; even E. carnea and its hybrids do not seem to mind a little lime in the soil, but rich garden soil should be avoided for all these plants, as it is conducive of sappy growths. A sandy loam with the addition of peat is an ideal rooting-medium and ensures that dense, sturdy habit which is so desirable, as it reduces the need for pruning and increases the production of flowers. It has been said that in certain places there is plenty of the ordinary Heather on our hills and commons during summer, but that is no reason why the winter- and spring-flowering species and varieties should not be more extensively grown in gardens. Many a dull corner could be made bright and interesting with Heaths, and when once established the cost of upkeep is very small.

The Heaths that are especially good at present are Erica darleyensis; this fine hybrid is said to be a cross between E. carnea and E. mediterranea, and in flower is very similar to both parents, but in habit it is between the two, eventually reaching a height of two feet. This Heath has been in flower since November; the recent frosts and snow seem to have done it no harm, and at present it is as freely-flowered as any Heather on the moor during August. Other kinds in flower at present are Erica carnea var. King George, and E. carnea var. Queen Mary, both excellent forms and very freely-flowered. E. carnea praecox rubra, as its name denotes, is a much darker form. E. carnea var. alba and E. carnea var. Pink Beauty, are white and pink forms respectively. E. carnea gracilis is also useful. Amongst the taller forms E. lusitanica is worthy of note.

The beautiful Hamamelis mollis is again in full flower, and has been in bloom in the woodland since the middle of December. These Witch Hazels are charming at this period of the year, and here there is material for a charming picture in winter—if a group of Hamamelis mollis with its bright yellow, spidery flowers is planted on a ground work of Erica darleyensis. These and other forerunners of spring convey a message of hope to the enthusiastic gardener at this season of the year. *Rhius.*

IRIS GARDEN.

IRIS MINUTA.

This dainty little Japanese species (Fig. 39) is unknown in a wild state, and somewhat rare in cultivation Of lowly stature, the non-flowering growths carry slender leaves which may be so much as eighteen inches long, but the flowers rarely exceed six inches in height. The latter are yellow with dull purple spots, and very pretty. Although considered to be "fairly hardy," Iris minuta is a desirable pot plant for cultivation in a cold frame or a cool house, in which it will flower in May. The roots are tuberous, and according to the *Bot. Mag.* (t. 8,293), "these are found to bear many very small Potato-like tubers, in shape and size somewhat resembling the eggs of ants; these tubers may serve the purpose of the large, fleshy tubers met with on the roots of certain species of Asparagus."

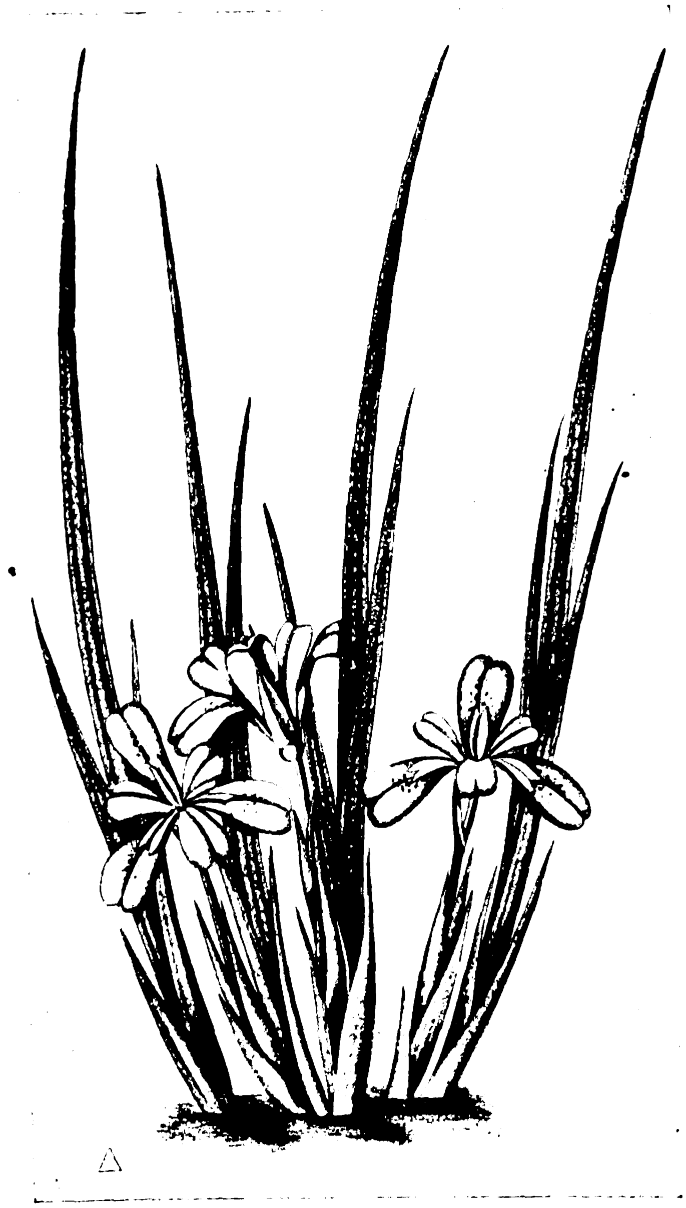

FIG. 39. IRIS MINUTA.

MESEMBRYANTHEMUM.

(Continued from p. 49).

3.—LITHOPS, N. E. Br.

This genus comprises stemless perennials consisting of one, two or several growths in a clump, in nature mostly buried in the ground, so that their tops are nearly, or quite, level with the surface. Each plant or growth consisting of an obconic or slightly compressed subcylindric fleshy body, which, when adult, has a transverse fissure all across the top, dividing it into two short contiguous (or under cultivation sometimes gaping) lobes, truncate and flat or slightly convex at the top; in the juvenile stages it often has only a small central orifice exactly as in Conophytum. Flower usually solitary, rarely 2-3 from the same growth, just exserted from the centre of the fissure. Calyx not membranous, partly or entirely exserted from the fissure, compressed, not produced into a tube above its union with the ovary, 4-7 (usually 5-6)-lobed. Petals many, free to the base. Stamens numerous, collected into an erect column or cone. Style short or almost absent; stigmas 4-7, filiform. Ovary inferior, 4-7-celled; placentas on the outer wall or floor of the cells. Capsule small, with 4-7 valves and cells; each valve with one stout central expanding-keel, or the expanding-keels contiguous for most of their length with the tips diverging, and with a broad membranous wing on each margin; cells open, without cell-wings or a tubercle. Seeds minute, sub-globose or slightly compressed-ovoid, with a short nipple at one end.—N. E. Br. in *The Gardeners' Chronicle*, 1922, v. LXXI, p. 44.

Species 19 at present known, natives of Damaraland, Great and Little Namaqualand, Prieska, Griqualand West, Transvaal, and the Karoo region from Laingsburg Division to Willowmore Division. The type of the genus is L. Lesliei, N. E. Br.

The name is derived from the Greek, *lithos*, a stone, and *ops*, face or appearance, in allusion to the resemblance of these plants to the stones among which they grow.

Fig. 40 is a diagram showing the floral structure of this genus.

The references to and descriptions of species that follow are additional to those already given in *The Gardeners' Chronicle*, 1922, vol. LXXI, pp. 55, 65 and 80, and bring the account of this genus up-to-date.

The members of this genus are great favourites with those who cultivate succulent plants, not only on account of their neat appearance, showy flowers and interesting character, but also on account of the remarkable way in which they imitate the stones and soil among which they grow. It appears to me, however, that it is not certain that we have arrived at a correct solution when we state that this mimicry of their surroundings is a real protection to the plant. It may be that it is; at the same time, it has recently occurred to me that as the eyesight of animals and birds is so much keener than that of mankind, and as the botanical collector is able to find these plants when he searches for them, why may not the hungry animal or bird with their much keener eyesight be able to do so too? They would surely sometimes find one or two, and the experience thus gained would teach them how to look for others. At least, that is how it appears to me. And, indeed, Berger, in his work on *Mesembryanthemum*, p. 11, records that Dinter has mentioned that baboons search for and eat Lithops pseudo-truncatella, so that they, at any rate, have learned how to detect it, in spite of the fact that it is a species that so closely resembles the stones it grows among as to be easily overlooked! Yet one cannot overlook the fact that the ordinary non-botanical person very commonly does fail to detect these plants, as I have recorded in *The Gardeners' Chronicle*, vol. LXX, p. 250, and vol. LXXI, p. 44.

Even when in flower, some of these mimetic species, I am informed by more than one South African observer, are practically indistinguishable from their surroundings at a short distance, and when out of flower and at rest, they are so inconspicuous that one correspondent, writing of mimetic species belonging to other genera than Lithops, writes of them, when in a resting condition: "I cannot find them, I can't think where they all get to." So that if animals and birds, in spite of their having keener eyesight and instincts than man, are, after all, only comparable with the ordinary non-botanical observer and not with the botanical collector, then there can be no doubt that mimicry would protect the plants. But can we assume that in the ages passed animals and birds, driven by hunger, have not learned how to use their keen eyes and distinguish these mimetic plants from their surroundings, even as the keen-eyed botanist has done? At present, it seems to me, that this subject of mimicry has not been so clearly solved as some appear to believe.

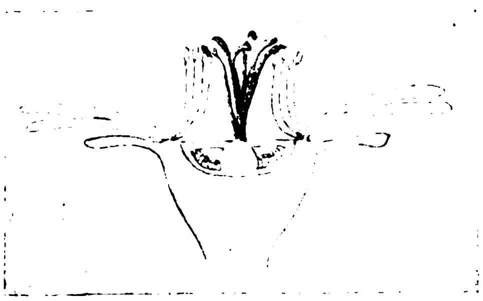

FIG. 40.—LITHOPS TURBINIFORMIS.
(Diagramatic section of flower).

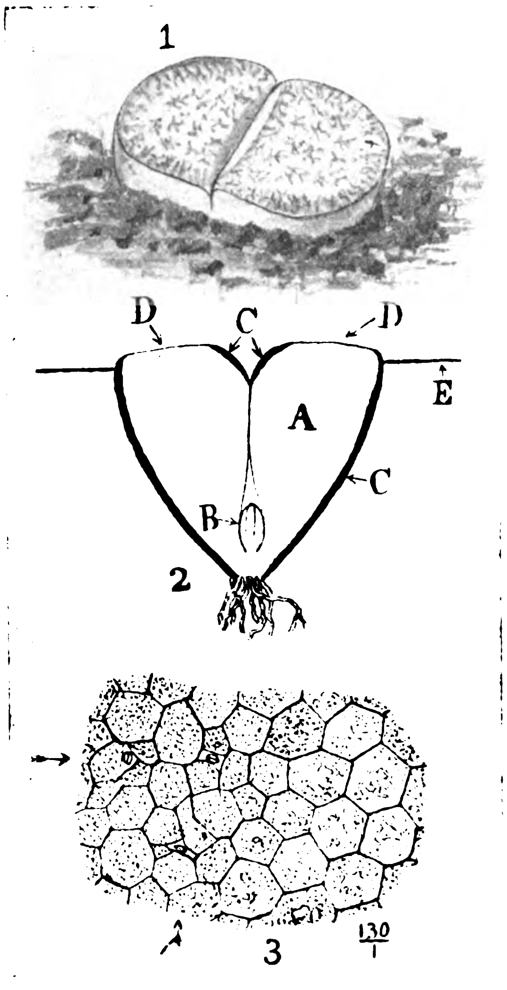

FIG. 41.—LITHOPS (MESEMBRYANTHEMUM) LESLIEI.

And there is another problem connected with this genus Lithops (and other genera that belong to the little group called "Windowed Plants"), which in nature are said to grow buried in the ground with only the top or windowed part of the leaves above the soil, of which the accepted solution is not quite a sufficient and satisfactory explanation, I think. I have given particulars and an illustration of the structure and mode of growth of this genus in *The Gardeners' Chronicle*, 1921, vol. LXX, p. 250, f. 112, and additional details of the same subject will be found given by Miss M. Karsten in the Dutch publication, *Succulenta*, 1925, vol. VII, p. 125. The above-quoted figure (Fig. 41) is reproduced here, and shows how the chlorophyll-layer (Fig. 41 C) is confined to the sides and gaping part of the fissure of the plant, most of it being underground, the top (Fig. 41 D) being the window which is destitute of chlorophyll.

The accepted explanation of the purpose of this arrangement (as already detailed at the place quoted), is to prevent the chlorophyll from being injured by the intensity of the light in its native region. But continued observations of the behaviour of this and other genera of "Windowed Plants" having the same general structure, has caused me to alter my opinion. For, as grown by myself, these plants do not like being buried in the soil; if planted so, the first new growth that they make always rises considerably above it, and a plant of a species allied to M. rhopalophyllum (which will later be found described under the genus Fenestraria) that I planted buried in sand, as illustrated in Dr. R. Marloth's splendid book *The Flora of South Africa*, vol. I, p. 207, t. 52, would not grow so, but soon made an elongated internode and raised its new crop of leaves entirely above the soil. One plant, however, that was watered from above, instead of from below, quickly rotted, and I have had two plants of L. Lesliei also rot that were planted with their tops level with the ground. This has caused me to believe that it is not the intensity of the light that injures the chlorophyll and causes the plant to bury itself, but the necessity of preventing the loss of water stored up in the leaves during the long periods of drought and great heat these plants have to endure. For, in the first place, we have the fact that there are many species of Mesembryanthemum, the species of Glottiphyllum, some of Gibbaeum and Conophytum, etc., that have green leaves or growths that are not at all glaucous and are fully exposed to the intense light and unharmed by it, while in Lithops itself the layer along the fissure is fully exposed, and in the tropics, the leaves of trees, etc., are also fully exposed to the light uninjured. In the second place, although being buried in the ground in their dry native country would protect them from too much transpiration, and to a certain extent the surrounding soil might even absorb and retain some of the moisture evaporated by the plant, which may possibly be re-absorbed by it again during the cool of the night, yet in the humid atmosphere of this country, except during the hottest summer weather, these plants evidently find it difficult to transpire sufficiently when buried in the soil, and hasten to get out of such stifling quarters. And in several instances I have found that in other stemless genera whose leaves are in contact with the soil, if watered (but not over-watered) from above when the atmosphere is rather humid, those leaves will occasionally rot where in contact with the damp earth. From these factors I have, therefore, come to the conclusion that it is for the conservation of water, and not to escape from the light, that these plants bury themselves in the ground and use the top of their leaves as a window.

Lithops Eberlanzii, N. E. Br.—Growths ⅔-1½ inch high, 7-16 lines broad, obconic, more or less circular or lunate in outline, and flattish or very slightly convex at the top, with a transverse fissure 2½-5 lines deep, of a pearl-grey-ochreous or pearl-grey, violaceous colour, marked with branched lines. Flowers unknown. Capsule about 4½ lines in diameter, 5-celled.

Mesembryanthemum Eberlanzii, Dinter in *Fedde Repert., Beihefte*, vol. XXIII, p. 43 (1923), and Dinter and Schwantes in *Zeitschr. f. Sukk.*, vol. II, p. 25 (March, 1925).

Great Namaqualand: On Kuckaus-Pockenbank Flats, Dinter, and on Kovis Mountains, Eberlanz. *N. E. Brown.*

(To be continued).

NOTES FROM WISLEY.

THE flowering period now covered by Crocuses is a very long one, and from autumn to spring one may nearly always find some Crocus species in bloom at Wisley. At the present time, the yellow-flowered Crocus Korolkowii, and the lilac C. laevigatus are in flower. The latter properly belongs to the autumn-flowering species, although it is one of the latest to bloom.

In the alpine house the brilliant blue flowers of Lithospermum rosmarinifolium are conspicuous. The only other blue flowers to be seen are those of Omphalodes Luciliae, which belong to the same order, but they are of a very much paler hue. Many pretty Saxifrages of the Kabschia group are now flowering, such as Saxifraga Burseriana major and S. Kellereri which is a hybrid raised in the royal gardens of Bulgaria. Another attractive hybrid is one named "Ada," which bears some of the characteristics of S. lilacina. The recurving petals are white, faintly tinged with mauve, and enclose a ring of red anthers.

At the summit of the rock garden, a group of Primula Winteri has been flowering since December 1. It is very noticeable that the most robust plants are those which are best protected by the overhanging rock.

A wild belt, consisting chiefly of Conifers, has been planted along a portion of the north side of the gardens; this should favour the growth of many of the less hardy shrubs situated in the wild garden, which have frequently suffered on account of cold winds.

Among the Oak trees, Hamamelis mollis is flowering. The same species is also to be seen in the shrub borders, where the taller H. arborea is in flower. The flowers of the latter are smaller, yellower and have twisted petals, but lack the delicious fragrance of those of H. mollis.

Commercial fruit trials are now being conducted in conjunction with the Ministry of Agriculture, on the new ground taken over by the Royal Horticultural Society at Wisley. About fifteen acres have been planted with fruit trees, including most of the well-known varieties and many new ones, which may possibly have market value. *J. E. G. White.*

NOTES FROM EDINBURGH.

THE influence of the recent spell of mild weather upon plant life is revealed in the early opening of some flowers on plants of Daphne Mezereum in the rock garden. Not far away are the rich yellow flowers of Hamamelis japonica arborea, whose praises have already been sung. This is a taller growing plant than the type, which is further distinguished by its lemon yellow flowers. There is another free-flowering variety cultivated under the name of H. j. Zuccariniana, which has pale yellow petals, a greenish brown calyx, and further commends itself to cultivators by the production of finely-coloured foliage in early autumn. Hamamelis japonica was introduced from Japan in 1862, but it was not until 1898 that the finest species was introduced in the form of H. mollis, a native of China. Not only is this the finest species of the genus, but it is also one of the finest flowering shrubs in cultivation, and the Royal Horticultural Society performed a graceful act in selecting this plant as the first recipient of the Award of Garden Merit.

Under glass, there is, as usual, a number of interesting plants in flower. In the corridor there is a fine specimen of Camellia japonica, with double pink flowers. The plant is trained on a wall, and when in full flower is a very handsome and decorative subject. There is also a double white-flowered variety, C. j. candidissima, but this does not appear to have the substance of the pink variety as the flowers fall to pieces more quickly. A plant of Jasminum primulinum trained up a pillar in the Centre House, now presents its large, pale yellow flowers.

The Leguminoseae supplies us with a very handsome decorative plant in Chorizema splendens ilicifolium, a native of Australia. The red and brownish-yellow colour of the flowers, combined with the small, Holly-like leaves render it valuable for decorative use. Another decorative plant is Eugenia apiculata, which possesses fine green leaves and produces a quantity of shining black berries. In the Palm House is a very tall specimen of Eugenia myrtifolia, which produces both flowers and fruits in abundance. Indeed, it flowers practically the whole year round, and its fruits are pink in colour. Fuchsia parviflora is another valuable fruiting plant. It produces its small, deep pink flowers freely throughout the spring, summer and early autumn, and these are succeeded by shining, black fruits produced in equal abundance. It is a rather tender plant, but succeeds well in the Rock House at Edinburgh and with its modest requirements and its ornamental features should be more widely cultivated than it is.

Among stove plants, Aphelandra aurantiaca Roezlii is of considerable value as an ornamental subject, its flowers being surrounded by bracts of a fine red colour; it readily responds to pot culture. Recently, a member of the Bromeliaceae was worthy of notice—Billbergia Saundersii—a plant of garden origin, with peculiarly variegated foliage. The flowers are very handsome, consisting of a dark blue corolla associated with red, while the stamens produce an abundance of golden pollen. *Robert H. Jeffers, Edinburgh.*

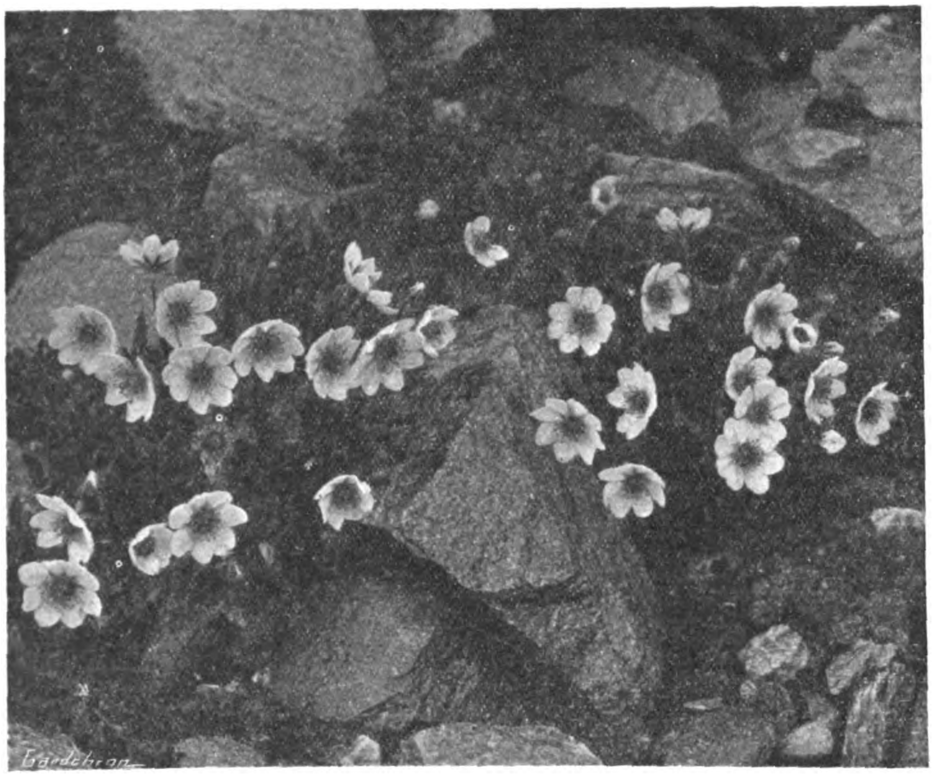

FIG. 42. DRYAS OCTOPETALA ON THE TOURLMAN GLACIER.

ALPINE GARDEN.

DRYAS OCTOPETALA.

THIS charming species of Dryas is probably the best of its genus for garden ornamentation; given a position in full sunshine on a rock garden and planted in a compost of crumbly leaf-soil, loam and sand, it will make dense mats of bright, toothed leaves, which are bright green above and silvery beneath. Even when not in flower a good specimen is a delight, but when summer comes and the plant is studded over with its pure white, wild-Rose-like flowers, each with its central bunch of yellow stamens, the picture is one of satisfying beauty to all except those who need a blaze of colour to arrest their attention. In its native Alps (Fig. 42), Dryas octopetala thrives in limestone formation, although it does not despise granite. Under successful cultivation, the species may be increased by division, or by layers. Plants may also be raised from seeds but this is a slower method.

SOME LINARIAS.

ONE of the least rampant of the trailing Toadflaxes is Linaria (Chaenorrhinum) origanifolium, a trailing alpine from the Pyrenees. It makes a neat little mat of dull green foliage which is adorned the summer through with purple blooms. In a free, warm soil, L. origanifolium will prove quite permanent, but it is a sun lover, and in certain districts may be the better for some protection from excessive rain and soil splash. It is an admirable subject for a dry moraine.

L. alpina is generally accorded the place of honour in this genus, and well it deserves it, for in all its forms it is a singularly charming plant. Unfortunately, however, it is by no means perennial in many gardens, the plants even though self-sown, gradually disappearing through no apparent cause. It has been stated that fresh soil will restore L. alpina as basic slag will bring Clover into a lawn, and there is doubtless something in the assertion.

L. hepaticaefolia, the smallest in leaf and flower of the creeping species, is a beautiful little plant, hugging the soil or the rocks as closely as Arenaria balearica and all the season through its pretty foliage is beset with the little purple flowers. But delightful as it is, even this dainty thing is not one to risk among the choicer inhabitants of the rock garden. I use it about steps and flagged walks, where it can safely be left to ramp as much as it will, and for such a purpose it is an ideal subject.

Many of the annual Linarias are very lovely with their slender, Flax-like stems and terminal spikes of many-hued flowers. Few annuals are more easily grown, the seed being sown thinly in spring where the plants are to flower. L. reticulata, with purple flowers, and its varieties in rosy-lilac, orange and other tints, is one of the best of these. L. maroccana, which gives us violet, blue, pink, rose-carmine and other shades, should also be noted. Then there is L. multi-punctata, only about six inches tall, with velvety black flowers speckled with gold, and various useful hybrids. All of the above, save L. multi-punctata, are about one foot in height. They should be sown in generous patches to be effective. *J.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.

Urgent Communications.—*If sent by telegraph, these should be addressed "Gard. Chron.," Rand; or by telephone, to Gerrard,* 1543.

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

PROPAGATION OF IVY BY ITS LEAVES.

During the investigation of a fungous disease of the Hop plant, it was desired to secure gradual decay of the leaves, in which thick-walled resting spores are formed. In a recent paper,[*] Dr. J. S. Bayliss-Elliott and Miss O. P. Stansfield stated that Ivy leaves, when buried, decay very slowly, and can therefore be utilised for the subsequent location in the soil of other more easily decaying leaves buried with them. In employing this method in the present instance, it was by chance observed that some of the Ivy leaves had developed adventitious roots.

It is interesting to recall in this connection that certain species of plants are known to give rise vegetatively to new plants by the formation of roots and aërial shoots on their leaves. In some cases adventitious buds develop viviparously on the uninjured leaf; Asplenium bulbiferum and the various species of Bryophyllum are widely separated instances in which this normally occurs. The abnormal development of buds or leafy shoots on the leaf and leaf-stalk is not infrequent; of this there have been records in the Cabbage, Tomato, Crown Imperial, Calliopsis (C. tinctoria), Cuckoo Flower (Cardamine pratensis) and the Bulbous Buttercup, to mention but a few plants of differing habits and affinities.

As is well-known, the development is often stimulated by injury to the leaf, particularly where severance of the vascular bundles is involved. Indeed, in many cases injury to or removal of the leaf is an essential preliminary to bud development; a remarkable instance is recorded by Caspary[†], who, by making incisions, obtained the development of over a hundred "male" flowers on a single leaf-stalk of a Cucumber plant. The stimulus would in these cases appear to be given by the abnormal accumulation of plastic foods in the leaf as a result of the interruption of the usual path of translocation to the stem. A new plant, however, can only develop from foliage in those species possessing leaves which are able not only to regenerate by the production of adventitious buds and roots, but also, due to structural or physiological peculiarities, to tolerate the severe restrictions on water supply until roots are developed—no mean feat when the activities of a normal leaf are considered.

These facts explain the limitations to the utilization of leaf cuttings, though it is a well-known method used in the propagation, for instance, of the choicer kinds of Begonia semperflorens and certain other species as well as garden varieties of Begonia, Bryophyllum, Gloxinia, Achimenes, Ficus, Peperomia and also of many succulent xerophytes. The details of the actual practical operations in the present instance are worth recording.

On November 18, 1924, several nine-inch pots were prepared in the following manner. Two-thirds of the pot was filled with loam; on this was placed a layer of about two inches of fine gravel and sand, which was then covered with freshly gathered Ivy leaves, the stalks of which were nipped off close to the leaf in order that this layer should be as flat as possible. The portions of Hop leaves which were to decay were next placed in position, and a further single layer of Ivy leaves deposited on them. Dry silver sand was poured on to this uppermost layer of leaves until sufficient had been added to keep the somewhat springy leaves pressed down. Here and there, at the edges of a pot, part of an Ivy leaf might be seen projecting. The pots, thus prepared, were placed on wide, gravel-covered shelves of an unheated greenhouse, and after one thorough watering, the surface sand remained damp for several weeks. Only occasional waterings were given, but as the weather became warmer, the pots were placed close to others containing growing plants, and they then received a share of the watering at regular intervals, without special attention being bestowed upon them.

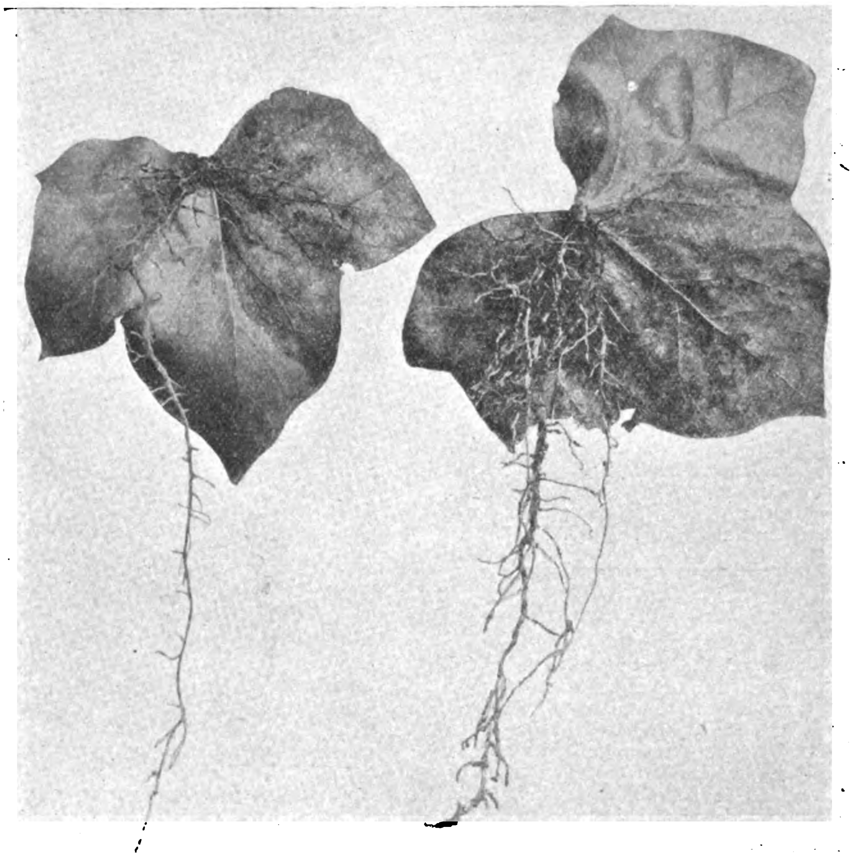

FIG. 43.—DEVELOPMENT OF ROOTS FROM IVY LEAVES WHICH HAD BEEN BURIED THIRTEEN MONTHS.

Some of the pots were "turned out" in the spring months for examination of the remains of the Hop leaves, but three, no longer required, remained in the house, and were more or less neglected from the end of July onwards. For several weeks they received no water, and during the summer the sand was often quite dry. Occasionally, during autumn—more by chance than by intention—they received water, and moss and weeds were growing on the surface when the pots were finally "turned out" on December 15, 1925—thirteen months after "planting." It was then found that several of the Ivy leaves had developed long roots from the point at which the petiole had been nipped. Some of the leaves had turned brown in parts, but none was completely decayed. One only, of those which had rooted, was brown over a quarter of its area; the others were still green. A cap of callus tissue had grown over the exposed end of the petiole (6–7mm. wide), and the roots had their origin at this callus. Of the two leaves illustrated in Fig. 43, one was five-and-a-quarter inches broad and three-and-three-quarter inches long, the other four and-three-quarter inches broad and three-and-a-half inches long. From the callus of the former there were two roots seven inches and five-and-a-half inches long and from that of the latter there were four roots which branched immediately. The longest was eight inches. No effort to produce above-ground parts appeared to have been made: there were small projections on or near the callus, but it was not determined whether these were adventitious buds or young roots.

There is no point of great economic importance in the above observation, but it indicates that Ivy, so often a pest in shrubberies, may possibly be distributed by clipped-off leaves which have been left on the ground or lightly covered. Beyond this, the phenomenon is probably only a matter of interest. *R. T. Pearl and W. M. Ware, South Eastern Agricultural College, Wye, Kent.*

DAFFODILS IN TASMANIA.

THINKING it may interest some of your readers, more particularly those who are growers of the Daffodil, I enclose a photograph of some of the recent productions of our leading Tasmanian hybridist, Mr. J. H. Hinsby, of Taroona, near Hobart, who is known in Tasmania, as the late Peter Barr was in England, as the Daffodil King.

A surveyor by profession, Mr. Hinsby enjoys the distinction of being known throughout Tasmania as a pastmaster in the art of hybridising, not only the Daffodil, but several other flowers. The Carnation in particular has claimed much of his attention in recent years, and we owe him much for the results he has achieved. However, I will confine my notes to a brief description of the Daffodils under review (see Fig. 44).—No. 1 is a very clear-coloured Incomparabilis, raised from an unnamed seedling × Tamerlane and produced this first bloom in September last. No. 2 is a 1922 seedling named Mimosa. It is very deep gold colour, with strong perianth, and large, level trumpet; it has twice been awarded chief honours for a yellow Ajax variety. Its parents are Monarch × P. R. Barr. No. 3 is a Leedsii variety obtained by crossing a fine Giant Leedsii seedling on to Mermaid. This produced its first flower in September, 1925. No. 4 has also Mermaid as one of its parents; in this case Mermaid was crossed with Banjo (Patterson; poeticus). No. 3 and 4 will undoubtedly improve next season, but already they have won many admirers.

No. 5 is a very rich, velvety yellow self named Eldorado, and is the product of Monarch × Queen Anne (Jonquil). No. 6 is the result of crossing Madame de Graaff with Minnie Hume (the latter being the seed parent), and it has a pure white trumpet, good in every respect; it has an exceptionally long stem, and is a fine grower. Nos. 5 and 6 were first shown in 1923. Nos. 7 (Maud K.) and 8 (Linda K.) are two very fine bicolor trumpets of great substance, yet carrying that refinement necessary in a show bloom. Of the set shown in the photograph (Fig. 44), No. 2 is perhaps the only one faulty in the perianth segments; it will be noted that these are narrow, though strong. This variety has excellent perfume, however, and proves to be extremely prolific and free blooming.

It may surprise some of your readers to learn that many of Mr. Hinsby's best seedling Ajax varieties are indebted to the old Queen Anne Jonquil for parentage, and many of the seedlings carry the unmistakably rich perfume of the old Jonquil. At the annual Daffodil show of the Hobart Amateur Horticultural Society it is not unusual for Mr. Hinsby to exhibit over one hundred seedling Daffodils, comprising Ajax, Incomparabilis, Leedsii, Barrii, Triandrus and poeticus varieties; his latest and perhaps most sensational seedling is of the poeticus type, with large, pure white, overlapping, perianth segments, perfectly flat, and circular, with an "eye" which is very double, carrying blends of citron, orange, white and gold. I regret very much not being in time to obtain a photograph of the first bloom, which was christened Vera Robinson. I hope, however, to forward a photograph next season for the benefit of those British friends who are interested in Daffodils.

In conclusion, I may mention a beautiful deep golden Ajax variety, with a trumpet of immense size and long stem, named Peter Dawson; a bicolor of great quality named Green Mantle, and a pure white trumpet Daffodil of splendid quality, named White Icicle, all of which have already gained the highest awards at our Daffodil exhibitions. *W. J. McWilliams Hobart, Tasmania.*

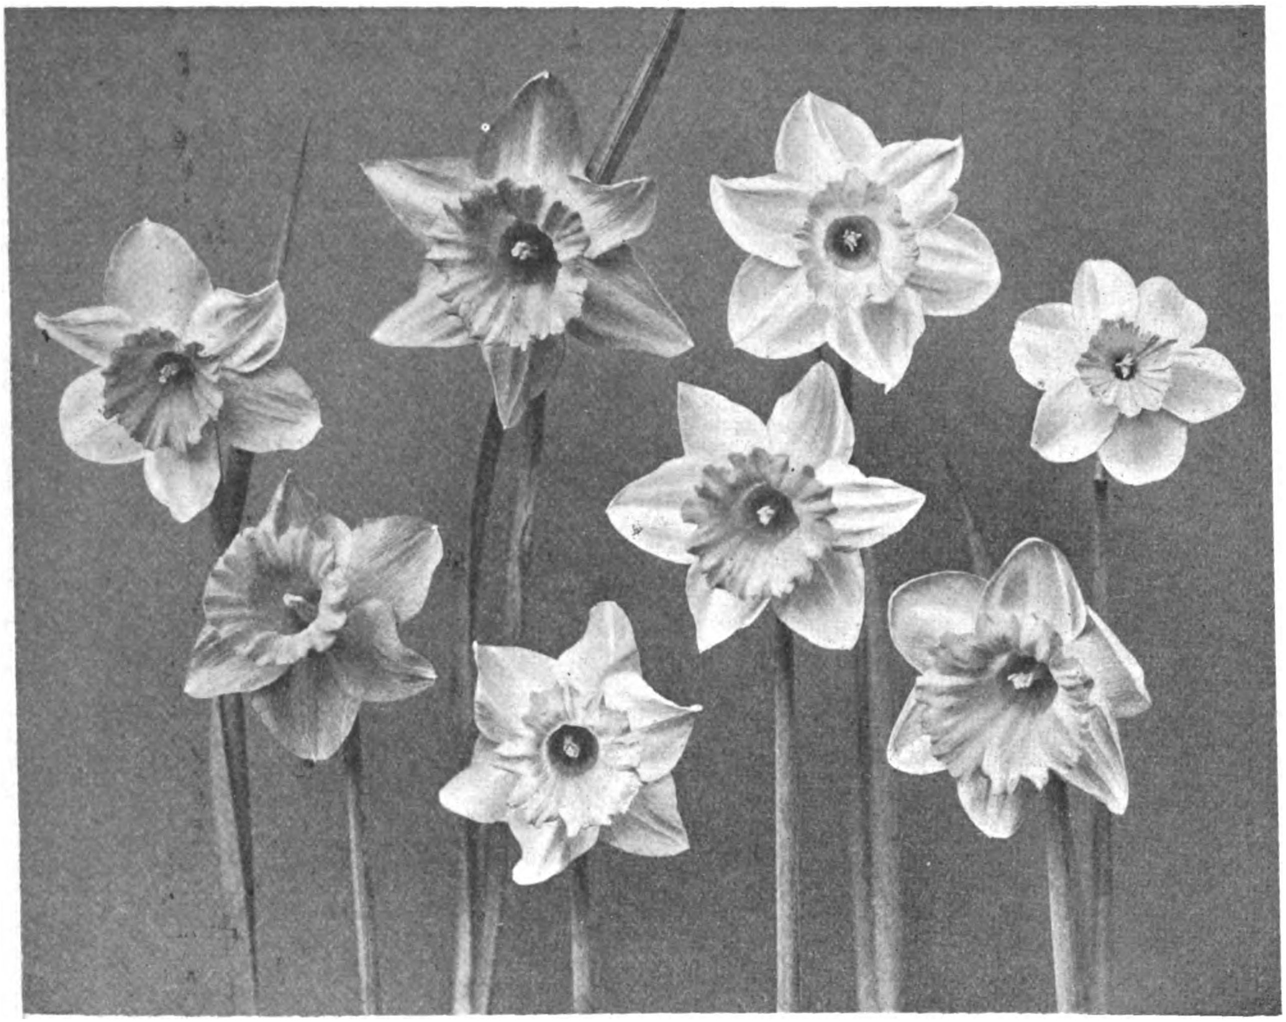

FIG. 44.—NEW TASMANIAN DAFFODILS.

No. 1 (1925). No. 2 (1922). No. 3 (1925). No. 4 (1925).
No. 5 (1923). No. 6 (1923). No. 7 (1924). No. 8 (1924).

SNOWDROPS.

THE season of the Snowdrop is now almost with us again, and I have been looking up the various contributions made to *The Gardeners' Chronicle* during 1924 and the spring of 1925, when the point of discussion mainly centred on the question whether the Snowdrop in its wild state did or did not produce viable seeds.

Formakin stated that, so far as his observations went, it did not do so, but later, in the issue of November 15, 1924 (p. 340) he quoted a letter from Professor Wright Smith, Royal Botanic Garden, Edinburgh, to the effect that, while seeds, removed from their capsules and sown immediately on their arrival from *Formakin*, had failed to germinate, other capsules which had been left on a light dry shelf until thoroughly ripened, had produced a few seeds which had germinated.

This, following upon the opinions expressed by Sir Herbert Maxwell—*Gard. Chron.*, April 5, 1924 (p. 189); A. T. Johnson, (ibid. p. 211); S. Arnott (ibid. p. 227); M. Weiss (ibid. p. 223): Parkin (ibid. p. 185): and F. H. Chapman (ibid. p. 65), seemed to settle the point that the Snowdrop is capable of reproducing itself from seeds. But when your correspondent Mr. A. T. Harrison, Culzean Castle Gardens, in May last stated (p. 303) that it seemed to him that the former correspondence had left the question in doubt, I wondered. I gathered and sent him a number of capsules in June. Acknowledging these, he wrote me that one thing that impressed him about capsules produced here was that in June they were still very green, and that they seemed to be almost at the same stage then as those which he had sent to you nearly two months before. I take it that this long continued greenness is a sign of continued activity in that the development of the seeds is still progressing. This seems very probable in view of Mr. Harrison's subsequent experience. In September he wrote me that he had then depodded the Galanthus nivalis capsules and obtained 180 plump seeds, but that from capsules "gathered and ripened" at Culzean he had "failed to get any seeds whatever." This astonished him greatly, and he sent me a number of these seedless capsules, which in outward appearance seemed identical with those I had sent him, except that his were more flattened. This I attributed to their being sent in an envelope by post. It was this somewhat amazing difference of behaviour that made me look up the earlier contributions on the subject and trouble you with this one. Seeing that while seeds are produced freely here, also at Rye (Sussex), and sparingly, if at all, at Culzean, Ayrshire, also sparingly at Formakin and at Ardgowan in Renfrewshire (as *Formakin* informs me), the question arises, "What is the reason for such difference of behaviour?" and I put forward the point in the hope that some with more leisure and more capabilities to investigate the subject will take it up.

A small exchange of bulbs has taken place between Mr. Harrison, *Formakin* and myself. In my own case, I have planted the bulbs in soil of a character as nearly approaching that in which Snowdrops do well here as I could make it up. During the flowering time, by leaving certain rows to be either self-fertilised or fertilised by insects and other lines to be regularlyartificially pollinated, if that be possible, I hope to find out whether there is any difference in behaviour as to seeding between the bulbs from different sources. I have not this season counted the bulbs at planting to ascertain their rate of increase by division.

Recently, I had the pleasure of a talk with Professor Wright Smith, and, as the outcome of it, while not ruling out the possibility of there being in the south a greater insect fertilisation I hazard the suggestion that here, with a medium rainfall (under 27 inches) and usually a somewhat dry spring with usually a hot spell in summer—and at Rye with similar conditions and a rainfall of 26 inches—the Snowdrop receives a check which induces it to resort to seed formation, whereas on the west coast of Scotland, where, as at Formakin, the average rainfall during the past four years amounts to something like fifty inches (almost forty inches average in six years) at Culzean, and thirty-six inches at Monreith, the impulse given to the roots may be rather to increase by bulb division than by producing seeds.

This theory seems to have some force of reason given to it by the statement by *Formakin* (*Gard. Chron.*, July 12, 1924, p. 28), "in a very few cases, and mostly on a bank which is well sheltered and fully exposed to the sun at midday, are to be found some large, plump, green fruit capsules (possibly where insects disport themselves and pollinate the bloom)." Being on a bank in full sunshine they may thus have a much drier rooting medium and this, rather than insect fertilisation, may possibly account for the freer production of capsules (and seeds ?) than he finds is the case in other places where he grows his Snowdrops so well, but gets no seeds.

Another point which leads me to make the suggestion is that a clump of Snowdrop bulbs which *Formakin* sent me as dug up, and which he states would be produced from three to eight bulbs (dropped into a hole about three or four inches deep), planted not more than ten years ago (probably only seven or eight) contained a much larger number of bulbs than any clump I have lifted here. At present it seems to me that, with him and in wet districts generally the Snowdrop produces offsets more than seeds, while in drier districts it may incline more to seed-production.

In your issue of April 5, 1924, p. 189, Sir Herbert Maxwell invited *Formakin* to give him a visit in May, when he would "show him myriads of swollen green capsules." It would be interesting to know whether the capsules did contain seeds in any quantity, or were, as Mr. Harrison's proved to be, without seeds; or, like the most of *Formakin's* "only contained a little damp, pulpy sort of stuff, like cotton wool."

In *Gard. Chron.*, April 12, 1924, p. 211, Mr. A. T. Johnson wrote: "Snowdrops always set seed here, and I have little doubt but what they spread by that means."

If they do really produce much seed with him in north Wales, with a rainfall of about forty-two inches, that is against my theory, and I hope he will make some further observations to test the point. If he and the other growers who have interested themselves in this question will do so, it may be possible to get new light on the behaviour of the Snowdrop in different localities. Hitherto, we all seem to have been recording our own ideas without considering that there might in truth be another point or view and experience. *P. Murray Thomson, Hereford.*

FORESTRY.

THE INFLUENCE OF PROLONGED DAYLIGHT IN THE VEGETATIVE SEASON ON THE QUALITY OF CONIFEROUS TIMBER GROWN AT HIGH LATITUDES.

(*Continued from p.* 67).

A COMPARISON of the Coniferous timbers from high latitudes with similar samples from lower latitudes seems to bring out the fact that, although it has an undoubtedly great influence upon it, its superior quality cannot be accounted for on the assumption that it is entirely due to its being of natural growth. Naturally regenerated Coniferous forests, although they are of comparatively rare occurrence now, are not unknown in this country, and there are records of such in the past. One well-authenticated case from Scotland is recorded in Evelyn's *Silva,** in a communication from James Farquharson, Esq., of Invercauld, in South-west Aberdeenshire, on June 22, 1775. The particulars as given by Mr. Farquharson are as follow:—"The finest Fir-trees appear in the most mountainous parts of the Highlands of Scotland, in glens, or on sides of hills generally lying to a northerly aspect, and the soil of a hard, gravelly consistence, being the natural produce of these places. The winged seeds are scattered in quantities by the winds from the cones to the adjacent trees, which expand in April and May with the heat of the sun; these seedlings, when young, rise extremely close together, this makes them grow straight and free from side-branches of any size, to the height of fifty or sixty feet, before they acquire the diameter of a foot: even in this progress to height they are very slow, occasioned by the poorness of the soil and the numbers on a small surface, which I may say makes them in a constant state of war for their scanty nourishment, the stronger and tallest by degrees overtopping the weaker, and when the winds blow they lash against one another: this assists in beating off any horizontal branches that might damage the timber with knots, as well as by degrees crushes the overtopped trees. In such a state of hostility they continue struggling until the master trees acquire some space around them; then they begin to shoot out in a more bushy manner at the top, gradually losing their spiral form, increasing afterwards more in size of body than height, some acquiring four feet diameter, and above sixty feet of height to the branches, fit for the finest deal board. The growth is still extremely slow, as is plainly proved by the smallness of the grain of the wood, which appears distinctly in circles from the centre to the bark. Upon cutting a tree over close to the root, I can venture to point out the exact age, which, in these old Firs, comes to an amazing number of years. I lately pitched upon a tree of two-feet-and-a-half diameter, which is near the size of a planted Fir of fifty years of age and I counted exactly two-hundred-and-fourteen circles or coats, which makes this natural Fir above four times the age of the planted one."

Allowing one inch as the thickness of the bark, the radial measurement of this naturally-grown Fir gives an average of approximately fifteen annual layers of wood to the inch, and it is interesting to compare this rate of growth with some particulars which Professor Fraser Story gives in the *Quarterly Journal of Forestry* for 1921* of Scots Pine in the primeval forest of Bialowieska, in the Province of Grodno, in Eastern Poland, which he visited in 1920.

The forest of Bialowieska, which covers 470 square miles, is situated on a plateau at an elevation of 500 feet to 600 feet above sea level, at approximately the 53rd parallel of latitude. It is mixed, but sixty per cent. of the crop consists of Scots Pine, which ranges in age from eighty to 200 years, with here and there a veteran 300, 400, or 500 years old. "The high quality of its timber," Professor Story remarks, "is partly due, no doubt, to the age of the trees. The annual rings are very regular, and the heart wood broad and resinous, although one does not find the extremely narrow-ringed timber obtainable from trees grown in the Archangel district . . . . One Pine taken at random as it lay on the ground measured 110 feet in length to a point where the top was broken off; at the middle it had a girth of seven feet nine inches, and at four feet three inches from the butt the circumference was nine feet nine inches." From these measurements it is impossible to make an accurate comparison, but as the centre girth given here is practically the same as the basal girth of the naturally-grown Invercauld tree measured by Mr. Farquharson, assuming it to be approximately the same age at that point, it shows that the rate of growth in girth is very similar for these two latitudes, the one with a continental climate, at the latitude of 53°, and the other (Aberdeenshire) with an insular climate, at the latitude of 57°. But Professor Story's statement that there "one does not find the extremely narrow-ringed timber obtainable from trees grown in the Archangel district," makes it quite clear that the wood rings of this timber are broader than those of the North Russian timber, the best of which gives over thirty wood rings to the inch, and which may be considered to be among the finest-grained Scots Pine timber grown. *A. D. Richardson.*

ORIGIN, EARLY HISTORY AND DEVELOPMENT OF THE POTATO.

(*Continued from page* 49).

Introduction into Spain.

Loudon,[*] quoting Sir J. Banks, states that the Potato came to Spain in the early sixteenth century. From Spain, where Potatos were called "Battatas," they appear to have found their way to Italy, in which country they received the name "Taratoufle." Authorities differ, however, with regard to the actual date, which Krichauff[†] and De Candolle place between 1580 to 1585. Hieronymus Carden, a monk, is supposed to have been the first to introduce the Potato into Spain from Peru.[‡] Although there is no actual record, so far as the writer is aware, of a direct introduction into Spain from South America, the probabilities are so strong as to amount almost to a certainty. It would have been a very exceptional human occurrence if the Spaniards, coming in contact so much with the tuber, had not taken specimens back to their native land. Snell[§] states that the Potato was first cultivated in Spain in the Province of Galicia.

Introduction into England.

Apart from the presumed introduction into Spain, the Potato is supposed to have found its way into Europe from another and entirely different source. It has been stated very frequently that the Potato was brought to England in 1586 by one of Sir Walter Raleigh's ships on its return journey from the colony which Sir Walter established in Virginia in 1584. This statement has been subjected to a very thorough examination by Mitchell.[||] In 1584, under Royal patent granted by Queen Elizabeth to Raleigh, there sailed on April 27, a contingent of colonists who landed in July on an island, called Wokoton. Subsequently, they removed to another island, Roanoak, twenty-one miles distant. They took possession of this latter island on July 13, and named the district Virginia. The following year, Raleigh reinforced these colonists by sending seven ships to Virginia under Sir Richard Grenville. This flotilla reached Wokoton on June 26, and Roanoak immediately afterwards. Grenville remained until August 25, when he returned to England, leaving one-hundred-and-seven persons behind him. These settlers remained on the island for a year, under the government of Ralph Lane. Ships were sent to deliver provisions to the colonists, but in some way they were delayed. In the meantime, however, Admiral Drake, returning from an expedition against the Spaniards at Carthagena, and the West Indies, called to see how his fellow-countrymen fared, and took them on board his ships. They left Roanoak on June 18, 1586, and arrived in Portsmouth on July 27 of the same year. Sir R. Grenville, with three ships, arrived at Roanoak later, to find the colonists gone. A fourth voyage was made in 1587, and a fifth during 1590, but no subsequent attempt at colonising was made until 1606.

Raleigh gave up his patent on March 7, 1590.

It is reasonable to assume that if the Potato came to England from Virginia in Raleigh's ships some reference would be made to it in the writings of the returned colonists. However, the only record of a plant, which in any way approached the Potato, is that given in the report of Thomas Heriot[*] dated February, 1587, published in Dr. Bry's *Collection of Voyages*. Heriot described a plant called "Openauk." However, his description is written from memory, as when the settlers left Roanoak, the difficulties of embarkation were such that writings, etc., were left behind or thrown away. Heriot was a mathematician, and his observations would probably be fairly accurate. He states :—

> "Openauk are a kind of roots of round forme, some of the bignesse of Walnuts, some farre bigger, which are found in moist and marsh grounds, growing many together, one by another in ropes, as though they were fastened with a string. Being boiled or sodden, they are good meat."

However, he does not say that his "Openauk" was introduced to England, not is any reference to it contained in contemporaneous literature. Some authorities have assumed that the Potato was intended, but many others suggest that the description more aptly fits the Jerusalem Artichoke, which is indigenous to some parts of North America. The inference has also been drawn that the English botanist, Gerarde, who described the Potato in his catalogue in 1596, and in his *Herball*, in 1597, drew the "Openauk." It is worthy of notice, however, that, although Gerarde mentions that he obtained Potatos from Virginia—indeed, he gives them the name "Potatos of Virginia,"[†] —he does not use the word "Openauk," nor does he state from whom or in what year he received the Potatos. There is no proof of any connection between the "Openauk" of Heriot and Gerarde's Potato. The only facts about which one can be certain concerning Gerarde, according to Mitchell, are (1) he learned from Clusius that the Potato grew naturally in America, and (2) that he obtained roots from Virginia which he grew in his garden. In considering the question, moreover, the possibility of some mistake by mixing in Gerarde's garden must not be overlooked. *J. P. McIntosh.*

(*To be continued.*)

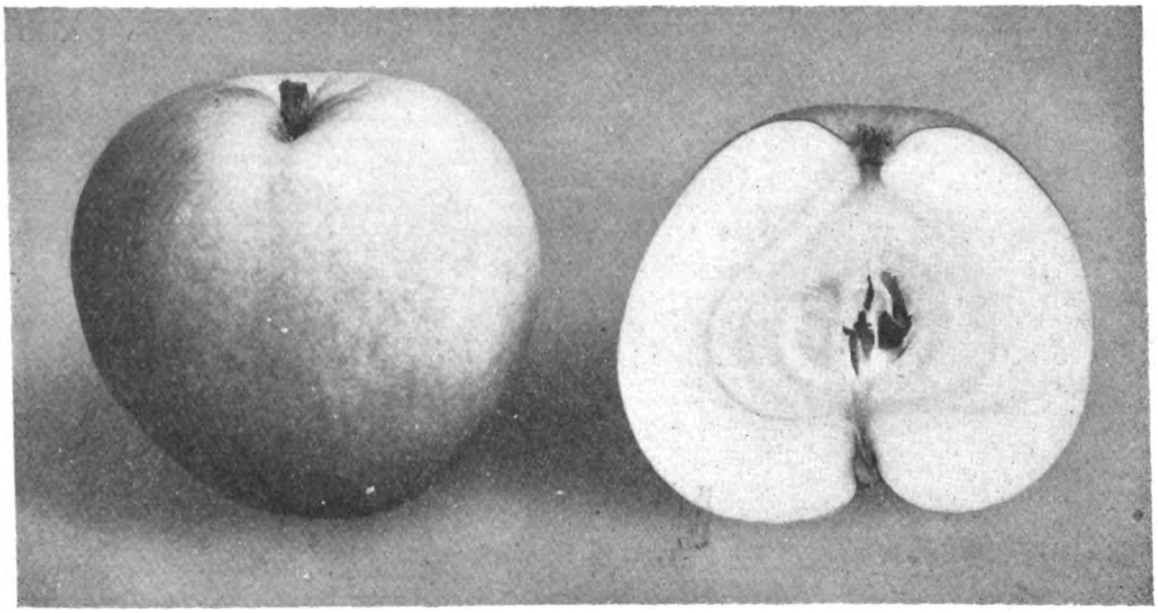

FIG. 45.—APPLE MOTHER.

FRUIT REGISTER.

APPLE MOTHER.

Of the numerous varieties of Apples which have originated in America none succeeds better in this country than Mother (Fig. 45), or as it is very frequently known—American Mother. It is of the Pearmain type and originated at Bolton, Massachusetts, but the year is uncertain, although it was recorded in U.S.A. before 1848.

This Apple stands high in the list of dessert varieties for quality, indeed, it is one of the best sorts in its season—October. The skin is yellow, covered with crimson on the side exposed to the sun and strewed with russet dots.

The flesh is yellowish-white, tender, juicy, sweet and richly flavoured. The fruits are of a size suitable for dessert purposes, and a dish of this choice Apple is often included in a collection of dessert fruits at autumn exhibitions.

The tree is a moderate grower and crops fairly well; it gives excellent results trained as cordons and fruits from cordon trees are of exceptionally fine quality.

FOREIGN CORRESPONDENCE.

BUCAREST FLOWER SHOW.

THE third annual exhibition of flowers, fruits and vegetables, which was held in Parcul Carol, Bucarest, Roumania, on November 7 to 11, 1925, was a great success. Their Majesties, the King and Queen of Roumania, who again opened the show, were accompanied by the Crown Prince and Princess, the ex-King George of Greece, The Princess Bibesco, also the Prime Minister, Mr. V. Bratianu, and Madame Bratianu, who takes a great interest in the show.

The King made a short speech on the lovely flowers and fruits which were exhibited, wished the society great progress, and complimented all who had helped to make the show a success. The President, Mr. C. Farando, responded to the King's speech, and thanked him on behalf of the society for coming to open the show. He stated that the weather had been unfavourable to gardeners at different periods of the year, and hailstorms had done much damage in different parts; the intense heat in August had also affected their gardens adversely.

The chief competitors were Messrs. C. Farando and Sons, Bucarest, who showed very large blooms of Chrysanthemums in perfect condition, the varieties including William Turner, Yellow Turner, and Daily Mail (*Hors Concours*); M. Jean Lacroix, Bucarest, who had a mixed group of Palms, Chrysanthemums, Begonias, etc., also a fine collection of fruit trees arranged in the open (Gold Medal of Premier); M. Theobald Scheidegger, Bucarest, who staged a finely-arranged group of mixed Palms, Ferns, Begonias, Chrysanthemums, etc. (Premier Gold Medal); M. F. Wilk, Codlea, Brasov, a specialist in Cyclamens and American Carnations, who had a group of very fine specimens of these plants (Gold Medal): H.M. The King (gr. Mr. F. Rebhuhn), who showed a decorated table a grand display of Cyclamens, etc. (*Hors Concours*); Prince Bibesco, Mojosoca (gr. J. W. Funge), who put up a magnificent mixed group of Single Chrysanthemums, Mary Richardson, Sylvia Slade, etc; Streptocarpus, Violets Princess of Wales and Lady Hume Campbell; Cypripedium insigne, and Geraniums, the colours of which were greatly admired, also a vase of English Carnations, including Saffron, Minerva, Topsy, Red Ensign, and White Pearl (Premier Gold Medal); M. Bratianu, Prime Minister, who showed a fine collection of fruits including Apples, Pears, Grapes, etc., all grown outside. The Muscat of Alexandria Grapes were well coloured and equal to those grown under glass (Premier Gold Medal); many more small exhibits were shown from different parts of the country.. *J. W. Funge, Palatul Mojosoca, Gara Buftea, Jud. Ilfov, Roumania.*

HOME CORRESPONDENCE.

Gardening in France.—Having just returned from a twelve months' sojourn in France, the differences in the gardening conditions existing in the two countries are worthy of note in the horticultural Press. Garden staffs have been reduced there but not to the extent in this country, and, generally speaking, the condition of most estates, from a horticultural point of view, in France, is not nearly so bad as in England. The trim tidiness of the English garden with its smooth grass lawns and efficiency of pre-war days was never equalled in France, in my opinion; the necessary preparation and after-care not having been given to grass areas, and the mowing, rolling, edging and general upkeep were not attended to with that meticulous care and thought which were given to them in this country. The mowing to-day is in a very backward state, and is done, even in the public parks and gardens of Paris, with a side-gear machine without grass-box, the grass being raked and swept up after cutting. The machines are mostly of American manufacture, and I found it impossible to obtain a roller and chain-driven machine with grass-box at short notice in May, in any of the large Paris stores, and was compelled to order in England. While the import duty was high, the saving of time and labour, to say nothing of the superior quality of the work done, quickly repayed the extra outlay. Unlike his confrère here, the French head gardener has great difficulty in finding enough men to complete his staff. Statistics recently published give the number of foreigners employed in France as nearly 3,000,000. Many men who were formerly employed in gardens have entered other industries where the call was more insistent, or the remuneration higher, leaving the gardening ranks depleted. The general prosperity of the country is very great. Kitchen gardening plays a very important part in France, and great care is given to providing an ample supply of saladings and *primeurs*, or early vegetables, fruits, etc., mostly by the hot-bed system of frames and lights, the French people eating raw salad of some kind with the mid-day and evening meals all the year round, if obtainable at a reasonable price. Their strains of Cauliflowers, Broccoli, Peas and Broad Beans, are not considered so good as ours, but their Lettuces, French Beans, Asparagus, Artichokes and others probably excel ours. The practice of covering all glass structures with Rye-straw mats in winter, in the place of the summer sun blinds, could be followed with advantage here, as I have recently seen 12° Centigrade of frost kept out by that means, thus economising in the matter of fuel—a question of vital importance here as in France. There is also a great revival in landscape gardening in France, and here again the difference of style is very marked. The prevailing style is that of the period of Louis XIV, with its long, straight avenues of trees, walled terraces, right angle bedding and rectangular sheets of water, similar to those at the Château de Versailles, and where the area is sufficiently large something of the majestic effect there obtained may be reproduced. In smaller places, however, the grandeur is lost without any compensating advantages, neatness, notwithstanding, never being entirely absent. The beautiful curves and undulations of our English landscapes, with their harmonious blending of natural shaped sheets of water and ornamental, bedding designs are more appealing to English taste. The French, in the past, have not been so thorough with their landscape work as in this country, and the magnificent ornamental trees which distinguish the grounds of our older English mansions have no counterpart in the demesnes of the châteaux of central France although the climate is no bar to their successful growth, as witness the rows of Paulownia imperialis which have been planted as avenue trees in the streets of Paris and the smaller French towns; these trees flower well most seasons. The noble Lebanon Cedars, so common here, are seldom seen, and an avenue of Sequoia gigantea, such as can be seen at Savernake, does not exist, while the Tulip Tree (Liriodendron) and Gingko biloba are not met with, except as quite small specimens. *Ben H. Martin.*

Perpetual-flowering Carnations.—I unfortunately overlooked Mr. Roy's letter, but my note was mainly written to growers who produce nothing but poor Carnation blooms, which are an undoubted danger to all interested in Carnations. As Mr. Roy follows out the wise method of propagating only from the best selected cuttings, consigns weak plants to the rubbish heap, and grows his plants with an abundance of ventilation and a minimum of fire-heat, my observations do not apply to him. Nevertheless, he is wrong in surmising that our nurseries are so close together as Haywards Heath and Wivelsfield; our wholesale, cut-flower nurseries are at Clayton, just off the South Downs, where the soil is totally different to our heavy clay at Wivelsfield; further, the climatic conditions are different to those in the Weald of Sussex, so there is a considerable change for the stock from one nursery to the other. We also periodically import fresh stocks of American varieties solely with the object of maintaining a sound constitution in our plants. I am obliged to Mr. Roy for his letter, because all discussions on the cultivation of Carnations are useful. A Carnation specialist regards those who produce good Carnations as his best friends, realising that the future prosperity of the flower rests upon its good reputation and a high standard of quality among private growers. *Montagu C. Allwood.*

Onions.—I have been interested in Onion growing for many years, and was surprised to read an article in *The Gardeners' Chronicle*, by Mr. George H. Copley, (p. 34, vol. LXXIX), advising growers to pot off Onions seedlings into thumb pots. Such a proceeding entails a lot of labour and is quite unnecessary to the production of a good crop of Onions. The seeds may be sown thinly in boxes four inches deep, with a layer of fresh horse droppings in the bottom; and the seedlings may be hardened off and planted in the open without further preparation. The plants root into the droppings and may be lifted with good balls of roots, but I have noted that the little plants always make fresh roots from the base after planting. It is not necessary to wait for a particular time to feed the crop; there is no critical time, and one may feed the plants so soon as they are established in their permanent quarters, and continue to do so up to the time they show signs of ripening. Premier and Ailsa Craig are, to my mind, only other names for Cranston's Excelsior. *Grigor Roy, Stoke d'Abernon Manor Gardens, Cobham.*

The Destruction of White Fly.—I have followed with interest the notes by your various correspondents on white fly. As one who has had experience with cyaniding for over twenty years, I wonder it is not more commonly resorted to by growers as I have found it a sure destroyer of white fly, and there is no need to do any spraying as advised by Mr. Meyer. All foliage should be absolutely dry, and the roots as dry as possible without allowing the plants to flag. Chrysanthemums in full bloom, and the delicate young fronds of Adiantum cuneatum will be uninjured if the instructions of the makers are carried out. I have found October or November the best season to use the cyanide, after the plants are housed for the winter, and before forcing has commenced. Then it is easy to keep all plants on the dry side without injury to them. From my experience with white fly, I do not think it survives our winters out-of-doors, therefore, every precaution should be taken to see that the pest is cleared from all frames as well as houses at this time. I have got rid of it with two cyanidings, but to be safe, three are advisable at an interval of a week to ten days. *A. W. Kidley, Aelybryn Gardens, Llanelly.*

——It does not seem to be generally known that "Abol" will kill white fly, used a little stronger than is recommended by the manufacturers for green fly. Either dip the plants in or spray them with the Abol. I have known white fly since 1888.. *Alfred Simeson, Everlands Gardens, Sevenoaks.*

——The observations by Mr. Meyer (page 35), are extremely interesting. His experience with tetrachlorethane, or one of its preparations, has indeed been remarkable. I should have thought that any substance capable of injuring any species of Crassula would have killed such a frail creature as the white fly. In the instance recorded in my note no serious damage was done. It is only fair to state, however, that flowers of the lighter shades of Pelargonium were injured, but no foliage was adversely affected. Of the efficacy of the treatment I have no doubt whatever. The house is now free from the pest and no other treatment has been given. Only a close and systematic investigation could expose the reason why three fumigations with tetrachlorethane usually destroys white fly. It would settle the question of whether the eggs are vulnerable at certain stages and whether the nymphs are destroyed. After I had read Mr. Meyer's letter, I wondered whether the house was quite dry when the chemical was liberated. This I believe to be quite as important when using tetrachlorethane as it is when using a nicotine fumigant. *George H. Copley, N.D.H.*

SOCIETIES.

BRITISH CARNATION.

THE annual general meeting of this Society, which was held at the R.H.S. Hall, Westminster, on January 12 last, under the presidency of Mr. J. S. Brunton, was rather poorly attended. Those present included Mr. W. E. Wallace, Mr. C. Engelmann, Mr. G. Allwood, Mr. M. Allwood, Mr. W. H. Page, Mr. H. T. Mason, Mr. E. F. Hawes, Mr. T. Stevenson, Mr. R. F. Felton and Mr. E. T. Willis.

The committee's report for the year ending December 31, 1925, recorded a membership of 356, and made special reference to the exhibitions which had been held during the year. Besides a gratifying increase in membership, there have been twenty-five new varieties of Carnations registered—the largest number in one year for a considerable period. During the past year the Witwatersrand Carnation Society of Johannesburg has become affiliated to the British Carnation Society, and it was stated that there is a fast increasing interest shown in Carnations in the colonies.

With the view to obtaining as full a record as possible of Carnations registered throughout the world, and to prevent duplication of names, it was agreed to ask affiliated societies to communicate the names of varieties registered by them. Mr. W. E. Wallace, the retiring chairman of committee, stated that he had written to the American Carnation Society asking for a list of their registered varieties, and the secretary of the B.C.S. was instructed to supply the American Society in return with a list of British registered varieties. The committee's report was unanimously adopted.

In presenting the financial statement, Mr. E. F. Hawes expressed great satisfaction with the Society's condition, and said he was particularly pleased to find that subscriptions generally had been paid very promptly. He was of the opinion that the two shows had been managed as economically as circumstances permitted. He reported a balance in hand of £57 17s. 11d., which, added to the previous balance, made a total balance of £107 3s. 5d On the proposal of Mr. H. T. Mason, seconded by Mr. T. Stevenson, it was agreed in future to show a profit and loss statement concerning the Society's *Bulletins*.

Mr. W. E. Wallace was enthusiastically elected president for the ensuing year, and in taking the chair, Mr. Wallace paid a tribute to the good work done for the Society by the retiring president. Mr. H. T. Mason was re-elected chairman of committee, with Mr. C. Engelmann as vice-chairman, and the hon. secretary and treasurer were re-elected. The following were elected to fill vacancies on the general committee :—Messrs. F. W. Aylesworth, D. Campbell, C. Engelmann, junr., —Hyde, F. Jordan, Jack Page, T. Paterson, T. Pinches, —Pulbrook, S. Salway and W. A. Sherwood. The hon. auditors, Messrs. E. F. Hawes and T. Pinches were re-elected.

THE ORCHID CLUB.

THE meeting held on the 15th ult., was rendered interesting and important by the extensive displays of Cypripediums staged by G. F. MOORE, Esq., Sir GEORGE HOLFORD and other members, illustrating the progress which has been achieved in the hybridisation of this genus.

PREMIER DIPLOMA.

Odontioda Gardenia (Oda. Colinge × Odm hybrid); a large well-formed flower, three-and-a-quarter inches in diameter. The sepals and petals are marked with a large central blotch of Indian-red, and have a broad, white margin in which there is a radiating violet flare; the lip is large, flat, with a small Indian red blotch. Shown by Dr. CRAVEN MOORE.

DIPLOMA OF MERIT.

Odontoglossum crispum var. Caronia. A large, rosy-coloured flower, three-and-a-quarter inches in diameter and of exceedingly fine round form. The sepals have central clusters of small red spots, which also mark the centre of the well-formed lip. Shown by Dr. CRAVEN MOORE.

Cypripedium Lawrebel, Paul's var. (Lawrenceanum × bellatulum). A particularly fine and well-coloured form of this old hybrid. Shown by F. T. PAUL, Esq.

GROUPS.

G. F. MOORE, Esq., V.M.H. (gr. Mr. W. H. Page), exhibited more than 200 cut flowers of Cypripedium hybrids raised at Chardwar, illustrating the great progress which had been made in the evolution of this genus by progressive hybridisation enduring over thirty years.

The collection contained typical examples of the finest forms of the many hybrids which have been raised, and the interest of the remarkable results attained was emphasised by the presence of some of the original parents. The Gold Medal of the Royal Botanical and Horticultural Society of Manchester and the Northern Counties was awarded to Mr. MOORE as a record of appreciation of the advance which he had achieved by hybridisation in the genus Cypripedium. The more noteworthy varieties shown were :—Crysostom vars. Amy Moore, Chardwar var., Blanch Moore, Rover and Heroine: C. Memoria vars. H. J. Elwes, Rex, The Queen and Premier: C. Doris Stanton and C. Gwen Hannen.

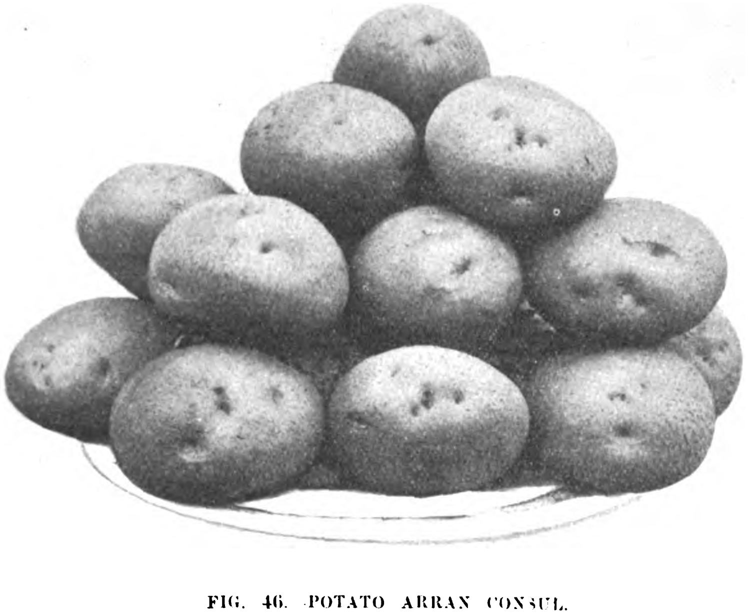

FIG. 46. POTATO ARRAN CONSUL.

Awarded the Lord Derby Gold Medal at the Ormskirk Trials, 1925 (see p. 74).

Sir GEORGE HOLFORD, K.C.V.O. (gr. Mr. H. G. Alexander), staged a small and elegant display of cut Cypripediums illustrating the lines on which this genus has been evolved at Westonbirt, the brilliantly coloured progeny of C. Fairrieanum being greatly admired. In addition to C. Reindeer, C. Baldur, Holford's var., C. Swallow, Westonbirt var., C. Marion Holford's var., C. Golden Fleece, C. Roundhead, C. Goldilocks, C. Minotaur, C. Ballet Girl, C. Lucifer, Holford's var.,C. Redwing and others; the exhibit included a brilliant form of Laelio-Cattleya Queen Mary, Sophro-Laelio-Cattleya Cynthia and the wonderfully coloured S.-L.-C. Falcon.

Sir WILLIAM THOM (gr. Mr. R. Williams), showed a fine collection of Cypripediums, including well-grown plants of C. Cappa Magna, C. Hermes, C. Maudiae, Westonbirt var., C. Briton's King, C. Elise var. Grand Monarch, C. Hestia, and a seedling of merit.

B. J. BECKTON, Esq. (gr. Mr. W. A. Stewart), staged an attractive display of Calanthes, Cypripediums and botanical Orchids, among which mention may be made of Calanthe Angela, Cypripedium J. M. Black, Beckton's variety, C. Ballyhandy, C. Roundhead, Westonbirt var., and a fine pan of Haemaria discolor.

Dr. CRAVEN MOORE (gr. Mr. W. Gilden), had an effective group of Odontoglossums and Odontiodas carrying full spikes, among which were strong plants of Odontioda Henryi, Oda. Joiceyi Odontoglossum amabile splendens, and several fine varieties of O. crispum.

A. T. CUSSONS, Esq. (gr. Mr. A. Daegleish), exhibited a mixed group of Cymbidiums, Calanthes and Cypripediums.

F. T. PAUL, Esq., F.R.C.S., showed Cypripedium Charlesworthii, Merle Dene variety, and C. Lawrebel, Paul's var.

GLASGOW AND WEST OF SCOTLAND.

THE opening meeting of the new season was held on Wednesday the 13th inst., when Professor J. Montagu F. Drummond, M.A., Glasgow University, delivered a lecture on "Mendel's Theory and its Practical Application." Mr. Charles Young, President, occupied the chair, and there was a large attendance of members, including several ladies.

After some preliminary remarks on the relations between pure science, and applied science in general, the lecturer gave a short account of the life and work of Gregor Mendel. The famous experiments with Peas were shown on the screen and described in detail and the importance of the central point of Mendel's theory purity of the reproductive cells (gametes) explained. Some of the later developments of Mendelism were afterwards considered, with special reference to their value to the practical plant-breeder, and it was pointed out that, while the employment of the Mendelian method in practice is subject to many restrictions, it nevertheless provides the breeder with a means of improving his stocks along pre-determined lines such as he never possessed before. Incidentally, Professor Drummond referred to the inheritance of perfume, quoting Sweet Peas as an illustration, and in the interesting discussion which followed mention was made of the correspondence in *The Gardeners' Chronicle* (vol. LXXV, 1924) on the loss of scent in Musk. One member suggested that fragrance was influenced by the temperature of the atmosphere.

The lecturer replied that while the atmosphere had something to do with the problem there was more in it than that, as the complaints about the loss of scent were not confined to Scotland Mr. John Cairns raised the question of colour variation in Ten-week Stocks, and Mr. Alexander McAlpine explained the difficulties he had experienced in applying Mendel's law to the breeding of Chrysanthemums. In reply to question, Professor Drummond expressed the opinion that although the Aster and the Chrysanthemum were members of the same family, they would not cross, as they were too distantly related.

ROYAL HORTICULTURAL

January 26.—A very bright exhibition was held at Vincent Square on this date, and there was a fairly good attendance. Spring flowers, Orchids, Roses, and Cyclamens all contributed to the display.

Orchid Committee.

Present: Mr. C. J. Lucas (in the Chair), Mr. Gurney Wilson (Hon. Sec.), Sir George Holford, Mr. F. J. Hanbury, Mr. H. T. Pitt, Mr. A. Dye, Mr. H. Alexander, Mr. Charles H. Curtis, Mr. J. E. Shill, Mr. J. C. Cowan, Mr. S. W. Flory, Mr. H. H. Smith, Mr. Stuart Low, and Mr. T. Armstrong.

Orchids were shown extensively on this occasion, but not so freely as at the previous meeting. Numerous interesting novelties were shown, and a Cultural Commendation was awarded to Messrs. Charlesworth and Co. for their splendid plant of Odontoglossum Dora, and a similar award to G. W. Bird, Esq. (gr. Mr. H. W. Reddens), Manor House, West Wickham, for a freely flowered specimen of Laelio-Cattleya Pioneer, Manor House var. Mr. W. Van de Weyer, Corf Castle, submitted a delightful little plant of Ophrys bombifera carrying two spikes of its bee-like flowers.

First Class Certificates.

Cypripedium Sir Trevor (*Ansuto var. Sallieri × aureum, × Christopher var. Grand Duke Nicholas*).—A superb Cypripedium and one of the very finest of the Chardwar hybrids. The flower is of perfect form, the big, rounded dorsal sepal being white with a pale green base. The petals and lip are light green, with a little yellow, a very pleasing shade. The Orchid Committee recommended the award of a Silver Lindley Medal in addition to the F.C.C. Shown by G. F. Moore, Esq. (gr. Mr. Page), Chardwar, Bourton-on-the-Water.

Miltonia Lycaena (*Princess Margaret × Lord Lambourne*).—This lovely hybrid has crimson petals shading to purple and with a white apex; the petals are white with rosy markings, and the big, rounded lip is white with a central and beautifully shaded area of bright rose, tinged with purple, and a pale cream mask with radiating rose lines. Shown by Messrs. Charlesworth and Co.

Odontioda Gwendoline, Stamperland var. (*Odm. eximium × Oda. Madeline*).—A showy and large-flowered hybrid, with rich reddish crimson sepals and petals, sparingly and daintily flecked with mauve. Lip cream-coloured, with red-crimson blotch and markings and yellow disc. Shown by R. Paterson, Esq., Stamperland, Cathcart, Glasgow.

Odontioda Colinge var. Rosemary (*Odm. crispum var. The Baron × Oda. Coronation*).—A very beautiful hybrid of rich and intense rose-red colouring. It has previously received an Award of Merit and now gained the higher award. Shown by J. J. Bolton, Esq. (gr. Mr. Lyne), Claygate Lodge, Claygate.

Awards of Merit.

Sophro-Laelio-Cattleya Vulcan var. Picotee (*L-C. Dominiana × S.-L.-C. Anzac*).—In this strong-growing hybrid the influence of Sophronitis grandiflora is not very evident, but the large flowers are very handsome. The broad petals are mauve with purple tinting and the petals are of rosier hue. The fine lip is deep Tyrian purple, with yellow in the throat and an edging of mauve. Shown by Messrs. Black and Flory.

Cypripedium Peerless (*Curtisii var. Sanderae × Holdenii*).—A chaste, albino hybrid of the C. Maudiae type. The white ground colour is finely veined with bright green and the lip is wholly of the latter colour. The foliage is dull light green with variegations of deeper green. Shown by Messrs. Armstrong and Brown.

Preliminary Commendation.

Odontoglossum Regium var. Britannia.—A handsome variety with light spottings on a deep chocolate coloured ground colour. Shown by Messrs. Charlesworth and Co.

Botanical Certificate.

Bulbophyllum Penicillium.—An interesting species with an elongated spike that rises a few inches and then bends in a horizontal direction. The spike is almost terete, with conspicuous bracts of a dull purplish colour as are the small flowers. The latter have a small, feathery lip which is curiously motile, moving in a jerking fashion with every movement of the air. Shown by J. Joicey, Esq., The Hill, Witley.

Groups.

Messrs. Charlesworth and Co.'s pleasing group contained splendid spikes of Odontoglossum Dora (eighty-nine flowers); O. Zula, deep hued and branching; O. crispum in fine form; O. Beau Brummel, very heavily branched, the old O. Wilckeanum, and other good things; there were also excellent examples of Miltonia Princess with crimson shading on the petals; M. Lycaena, with big, rounded flowers; Odontonia Nubia and O. Merops; and the big Cypripedium Senator var. Columbia; of botanical interest were Eria hyacinthoides, Cynorchis Lowii, Oncidium cheirophorum, and Coelogyne lentiginosa.

The contribution from Messrs. Stuart Low and Co. included graceful and bright hybrid Cymbidiums, Odontoglossums and Odontiodas, in addition to Cypripediums of the yellow insigne group, Bulbophyllum flavidum, Brassavola glauca, Platychinis Cobbiana, the rare Chysis aurea, Cypripedium Chamberlainianum and the sweetly-scented Odontoglossum aspidorhinum. Messrs. Sanders exhibited Odontioda Freda Sander of lovely rich rose colouring; Cymbidium Gottianum album, Odontioda Latona var. Enchantress, almost scarlet; Lycaste lanipes and a few other interesting plants.

Messrs. Cowan and Co. had a goodly group of well-grown plants which included Cypripedium J. M. Black, with finely marked flowers; C. Perseus (F.C.C. variety), C. Fantasia, C. Thompsoniana, the handsome Brasso-Cattleya British Queen which the firm seems to have in bloom always; Oncidium splendidum and Odontoglossum Theodora, a pretty O. Rossii cross.

Messrs. Armstrong and Brown showed two grand spikes of Laelio-Cattleya Schröderae, one with seven and the other with five beautiful blooms; their little group also included Cypripedium Peerless (Curtisii Sanderae × Holdensii), the brilliant little Laelia cinnabarina, L. harpophylla and Masdevallia tovarensis. Messrs. A. J. Keeling and Sons sent a few Cypripediums, including a pretty plant of C. Sunrise.

Some choice Odontoglossums were exhibited by Messrs. J. and A. McBean, these including O. crispum in variety, O. ardentissimum in variety, O. Theo, O. Pyraeus and O. Lilian. Cymbidium rosefieldense, Laelio-Cattleya Eunice alba, L-C. Sunbelle, of fine form, and the bright L.-C. Arcturus—an anceps cross—were also exhibited in this group.

Messrs. Black and Flory had some fine Cypripediums on view and a large plant of Sophro-Laelio-Cattleya Vulcan var. Picotee, with a mauve edging to the frilled purple lip. Mr. H. Dixon exhibited a few Orchids, notably Sophro-Laelio Marriottiana, Cypripedium quarryensis, and C. Winifred Hollington.

Floral Committee.

Present: Section A.—Mr. H. B. May (in the chair), Mr. Chas. E. Pearson, Mr. H. R. Darlington, Mr. D. B. Crane, Mr. J. T. West, Mr. D. Ingamells, Mr. A. Vasey, Mr. Jas. B. Riding, Mr. F. G. Cousins, Lady Beatrix Stanley, Mr. F. Streeter, Mr. Hugh Dickson, Mr. E. R. Janes, Mr. W. H. Page, Mr. J. M. Bridgeford, Mr. Donald Allen, Mrs. Helen Lindsay-Smith, Mrs. Ethel M. Wrightman, Mr. J. F. McLeod, Mr. T. Hay, Mr. G. W. Leak, Mr. W. B. Gingell and Mr. W. P. Thomson.

Section B.—Mr. Gerald Loder (in the chair). Mr. James Hudson, Mr. G. Reuthe, Mr. F. G. Preston, Mr. E. A. Bowles, Mr. L. R. Russell, Mr. A. Bedford, Mr. Clarence Elliott and Mr. R. W. Wallace.

Award of Merit.

Strelitzia kewensis.—This is a hybrid of S. Reginae and S. augusta which has been grown in the large Temperate House at Kew. In habit it partakes of S. augusta in being a tall plant nearly twenty feet in height and in having a branched stem. The flower spike is large, but the spathe is not so intensely purple as in S. augusta, while the flowers themselves are of pale primrose colour and lack the gorgeous colouring of S. Reginae. It would be a noble plant for the large stove house or warm conservatory. Shown by the Director, Royal Gardens, Kew.

Groups.

An admirable collection of forced bulbs in ornamental bowls was arranged by Messrs. Sutton and Sons. This occupied the whole of the tabling from the entrance to the Tea Annexe, and splendidly illustrated bulbs of high quality combined with first-class cultivation. The many Hyacinths, in distinct colours, demanded first attention. These were from prepared bulbs and largely of the graceful Cynthella type. The colours, particularly the blues and reds, were very clear, but the very best Hyacinths were the beautiful white spikes The many Tulips included both double and single varieties, which, as with the Hyacinths, were shown under colour names. Daffodils and Narcissi were of great merit and the beautifully arranged group also included Iris tingitana, particularly good Lily-of-the-Valley, and Freesias of considerable fragrance.

Large baskets of excellent plants of Iris tingitana, Iris reticulata, and Primula stellata in lovely shades of colour were staged by Messrs. Carter and Co., and these made an excellent display.

A full length tabling across the Hall was filled by Messrs. Blackmore and Langdon with a large collection of their admirable strain of Cyclamen latifolium varieties. These were set out in large baskets of distinct colours. Of the very many on view Salmon-Scarlet, Scarlet King, Giant White, Giant Crimson, and Grandiflora were especially admired, while many were fascinated by the frilled flowers of the variety Mrs. Buckston.

Carnations were shown in their usual high quality. Mr. C. Engelmann set up lovely vases of Mrs. Hamilton Fellowes, Rouge, Red Peerless, Topsy, Cupid, and many other valuable sorts. Messrs. Allwood Bros. showed vases of mixed varieties, and also Edward Allwood, Laddie, Maine Sunshine and Topsy. In a very good collection arranged by Messrs. Stuart Low and Co., White Pearl, Sheila Greer, Lady Hindlip and Philip Sassoon were prominent. At one end of the Carnations they staged Cyclamen latifolium varieties and Azaleas.

For so early in the year the forced Roses shown by Mr. Elisha J. Hicks were of great merit. The varieties were Madame Butterfly, Madame Edouard Herriott, Charles E. Shea, Mrs. H. Stevens, Coral Cluster and Double Orleans. Messrs. L. R. Russell, Ltd., staged a few plants of the blue-flowered Pycnostachys Dawei, with forced shrubs, amongst which the Wistaria and Azaleas were very well flowered.

Several plants of the brilliant Hippeastrum aulicum were shown by Messrs. R. Gill and Son with an extensive collection of their Poppy Anemones. They also exhibited trusses of Rhododendron Nobleanum, R. Cornubia and R. argentea.

A very attractive sandstone rock garden was built by Messrs. W. Cutbush and Son and planted with Rhododendron praecox, Hamamelis arborea, Iris reticulata, Crocus Sieberi, Saxifrages and other plants. The Messrs. Hopkins had a bright little rock garden and

Messrs. Skelton and Kirby planted their rock garden with Heaths, small Conifers and other shrubs.

With a background of profusely flowered Forsythias, chiefly F. intermedia and F. i. spectabilis, Messrs. Barr and Sons displayed splendid pans of Crocus Sieberi, Iris reticulata, Primula denticulata superba and the dainty little Narcissus minimum. Messrs. J. Cheal and Sons showed a few pans of Iris, Crocus, Adonis amurensis and Snowdrops. Saxifrages in small pots and Primula capitata were contributed by Mr. G. G. Whitelegg, while Mr. F. G. Wood staged a pleasant rock garden set out with various Primulas, Christmas Roses, Crocuses and dwarf Conifers.

Saxifraga Burseriana varieties, particularly dentata and crenata, were well displayed by Messrs. R. Tucker and Sons, who also showed drifts of S. Kellererii with various Primulas and hardy Cyclamens. Messrs. Waterer, Sons and Crisp staged a good batch of Pieris (Andromeda) floribunda, Rhododendron Nobleanum, Forsythia spectabilis, Crocus Cloth of Gold, Iris reticulata and Iris histrioides. Mr. J. Klinkert again exhibited good topiary specimens.

A large collection of their excellent photographs was exhibited by Messrs. Reginald Malby and Son, who also showed enlargements and several series of most fascinating colour slides.

Messrs. Wm. Wood and Son again showed an extensive selection of garden tools and sundries, and in a corner space there was set out one of Walker's Fruit Tree Protectors.

Fruit and Vegetable Committee.

Present: Mr. C. G. A. Nix (Chairman), Mr. W. Poupart, Mr. J. Cheal Mr. P. C. M. Veitch, M. Geo. F. Tinley, Mr. A. Metcalfe, Mr. H. Markham, Mr. W. Giles, Mr. A. E. Newby, Mr. A. Bullock, Mr. P. D. Tuckett, Mr. E. Beckett, Mr. H. Prince, Mr. A. C. Smith, Mr. W. H. Divers, Mr. E. A. Bunyard and Mr. A. N. Rawes.

There were only two exhibits in this section; the largest was a collection of forty-four varieties of Apples shown by Messrs. J. Cheal and Sons, Crawley. Most of the fruits were as sound and plump as when gathered from the trees; they were exceptionally clean skinned and the coloured varieties carried high tinting. The following is a selection of the varieties: Bowhill Pippin, Ontario, Crawley Beauty, Wagener, Hector MacDonald, Beauty of Kent, Sandringham, Arthur Turner, Buxted Favourite, Hormead Pearman, Prince Albert and Encore.

Messrs. G. Bunyard and Co., Ltd., Maidstone, exhibited a collection of Apples representing some of the best sorts in season. They showed the following fourteen varieties: Cox's Orange Pippin, Christmas Pearmain, Heusgen's Golden Reinette, Jonathan, High Green Blenheim, Lord Hindlip, Claygate Pearmain, Rival, Blenheim Pippin, Adams's Pearmain, Baumann's Red Winter Reinette, Ballinora, Belle de Boskoop and Norman's Pippin.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

Thursday, January 7.—Committee present: A. Hanmer, Esq. (in the chair), Messrs. R. Ashworth, C. Branch, A. Burns, A. Coningsby, J. Cypher, J. Evans, W. Giles, A. Keeling, E. W. Thompson and H. Arthur (secretary).

First-Class Certificates.

Cypripedium Mildred var. Margaret (Christopher Grand Duke Nicholas × bourtonense).—A fine flower with a broad, round, white dorsal segment, with deep rose-coloured markings; the petals are broad and the lip of even contour. From J. B. Adamson, Esq.

Cypripedium Eley, John Cypher's variety (parentage unknown).—A magnificent flower; the dorsal sepal is four inches across, white with a green base delicately spotted. The broad, wavy petals measure two inches in width; they are bronze-green, veined and spotted. From S. Gratrix, Esq.

Odontoglossum Pegasus var. Stanley Baldwin.—A well-shaped flower of deep maroon colour, paler at the tips; the broad, flat lip is tipped with white. From Mr. J. Evans.

Awards of Merit.

Cypripedium Woodhouse (villosum Beeckmanii × Alcibiades illustris) and *Odontoglossum crispum rotundum.* From Mrs. P. Smith.

Odontoglossum crispum Diadem and *Cypripedium Leeanum Adamson's variety (Leeanum Clinkaberryanum × bourtonense).* From J. B. Adamson, Esq.

Cypripedium Cappa Magna, West Point Variety (Cardinal Mercier × Nubian). From S. Gratrix, Esq.

Odontioda Priscilla var. Purple Shade.—From Capt. W. Horridge.

Cypripedium Elise, Wallhouse variety.—From James Wood, Esq.

Groups.

J. B. Adamson, Esq., Blackpool (gr. Mr. R. Taylor), staged a group to which a Gold Medal was awarded.

A Gold Medal was also awarded to S. Gratrix, Esq., West Point (gr. Mr. C. Branch), for a group of Cypripediums.

Mrs. Bruce and Miss Wrigley, Bury (gr. Mr. A. Burns), were awarded a Large Silver-gilt Medal for their collection of Orchids.

A Large Silver Medal was awarded to Messrs. J. Cypher and Sons, Cheltenham, for their exhibit.

HORTICULTURAL ORGANISERS' CONFERENCE.

A well-attended conference was held at the Midland Agricultural and Dairy College, recently, when Dr. Hatton, Director of the East Malling Research Station, opened a discussion on "Some Aspects of Black Currant Growing." Dr. Hatton stated that some years ago the East Malling Research Station obtained specimens of all so-called varieties of Black Currants available, and after careful study of them, they came to the conclusion that the naming of Black Currants was hopelessly involved, and that in reality there are only four distinct types, which fall in two main groups, as follow:—(1) Red Budded types: (*a*) French Group; (*b*) Boskoop Giant. (2) White Budded types: (*a*) Baldwin Group with long, ragged and protruding buds; (*b*) Goliath Group, with small, often crowded, adpressed buds.

He stated that it was only recently that any crossing had been done, and it was found that Black Currants breed true to type; the variety Baldwin tends to sport. He gave results of cropping trials carried out under uniform conditions for four years; the varieties were planted 1,200 bushes to the acre, as yearlings, and gave an average yield for the four years as follows:—Baldwin, 32 cwts.; Goliath, 25 cwts.; Boskoop Giant, 25 cwts.; Seabrook's Black, 23 cwts.; French (Black), 21 cwts.

They found that the variety Baldwin cropped earlier after planting than the other varieties, and in addition to the increased yield made double the price of Boskoop Giant, which clashes with the continental supply. Individual bush weights of fruit varied from fourteen ounces to thirty-five ounces, which indicates the necessity in carrying out any trials, of having a large number of bushes. He next dealt with some of the causes of non-cropping. He considered that some varieties cropped badly owing to the difficulty of pollination; in Baldwin, pollination is easy as the stigma and the anthers are of equal length, whereas in some others, the length varies very much. Dealing with the question of reversion, he mentioned that it could now be definitely stated that it is transmittable by grafting or inarching, and it has been suggested that the pruning knife may convey the complaint; proof of this, however is lacking. Reversion is clearly indicated about the middle period of growth. Bushes may look perfectly healthy during the summer, but still show distinct signs of reversion the following spring. Cutting out infected branches is considered ineffective. He pointed out that besides true reversion artificial reversion may occur if the terminal bud is removed and the axillary buds grow out prematurely; in such cases the plant later will grow naturally. Dealing with big bud at East Malling, they found that the most successful treatment was lime-sulphur wash (one in ten) which should be applied when the leaves are small, before the blossoms open; untreated bushes, after four years, had 6,000 big buds per 100 bushes, whereas lime-sulphur treated bushes had only 280 big buds per 100 bushes.

They found that reversion is increasing greatly in orchards where there is no treatment, but where growers are in the habit of spraying with lime-sulphur to destroy the big bud mite, it is found to have a beneficial effect in regard to both troubles, as the mite of big bud is evidently a carrier of reversion.

Obituary.

Frederick Bedford.—The very old friend with whom the writer had been more or less in touch with since first calling on him at Straffan Gardens, Co. Kildare, in 1878, passed peacefully away at his residence, the Bungalow, Leixlip, Co. Kildare, on the 19th inst. During his régime of forty years at Straffan Gardens they became noted, not only in our Irish gardening world but far beyond, for his skilled work as a plantsman and fruit grower. Retiring ten years ago to the quaint, old-fashioned house, perched high on the river's "brim" (the Liffey), he converted what was a wilderness into a charming little garden, thoroughly enjoying his labours of love, until a year since when an attack of illness rather severely handicapped him, physically, but not mentally, for his heart was in it right up to the end, the day before he died being spent in relabelling his beloved Roses. Mr. Bedford's first work in Ireland was at Kenmare House, Killarney, from whence, after a few years, he went to Straffan, and there got in touch with his friend the late Mr. F. W. Burbidge, then appointed as Curator to Trinity College Botanic Gardens, Dublin, who very frequently visited Straffan, and there are few more pleasant places, so quiet, restful and satisfying. Many happy memories by the writer go with him who was laid to rest in Straffan churchyard on the 22nd inst. with those he had loved long since and lost awhile, and was followed to the grave by his widow, daughter and three sons—the eldest of whom succeeded Mr. Hudson as gardener to Mr. Lionel de Rothschild, at Gunnersbury—and many friends. *E. K. Dublin.*

Edward Bull.—We learn with deep regret of the death of Mr. Edward Bull, proprietor of Bull's Food for Plants, and younger son of the late Mr. William Bull of Chelsea. Mr. E. Bull died on the 24th inst. at his residence, 41, Brunswick Terrace, Hove.

Hermann Fischer.—The death is recorded in our contemporary, *Möllers Deutsche Gartner-Zeitung*, of Herr Hermann Fischer, partner in the famous Stuttgart florist's firm of Julius Fischer, who passed away on December 18, 1925, aged 64. He was a splendid gardener, and the nurseries which supplied the shop were noted for the fine cultivation. Herr Fischer was very popular in Stuttgart, and took a very active part in founding and maintaining the local horticultural society. The business will be carried on as before by his brother, who has for some time been a partner in the business.

Rudolf Schlechter.—We greatly regret to learn of the death, on the 15th of November last, of Dr. Rudolf Schlechter, the celebrated German botanist and Orchidophile. Born in 1872, Dr. Schlechter showed early a great love of nature and of botany, and was sent out as a member of an expedition which visited West Africa in 1899 and 1900 to report upon the possibilities of developing Rubber cultivation in the German colonies there. In these and other journeys he found time for exhaustive records of the flora, and especially of the native Orchids, his last journey, still under the auspices of the Colonial Rubber Committee, to Malay and New Guinea, being in 1906-9. On returning home, he became assistant, and finally curator, at the Dahlem Botanic Garden. He wrote a number of very important works, chiefly of a systematic nature, on the subject of Orchids, his descriptions of new sorts alone running to over a thousand; his work *Die Orchideen*, was published in 1915, and contains over 830 pages. Schlechter was a painstaking observer and systematist of whom there are but too few, and will be sadly missed in scientific circles. It is probable that his knowledge of the flora of the eastern hemisphere was unsurpassed by that of any other botanist.

ANSWERS TO CORRESPONDENTS.

Acacia Baileyana. *G. J.* Acacia Baileyana is not very suitable for pot cultivation as it is apt to become bare and leggy and loses much of its older foliage. Your treatment is quite correct, but this species is seen at its best when planted out in a bed or border and trained up a pillar or rafter, cutting the branches hard back after it has finished flowering. When planted out it requires a run of at least ten to twenty feet, and on this account is not suited to a small house. Some of the best species for growing in pots are A. Riceana, A. pulchella, A. platyptera, A. armata, A. Drummondii, A. hastulata, A. longifolia var. mucronata and A. juniperina. You might try your plant in a larger pot, cutting back the branches after it has finished flowering, and repotting it when it is starting into fresh growth.

Chrysanthemums for December. *J. P. O'Dwyer.* Varieties to bloom in December and January are W. H. Lincoln, Winter Cheer, Tuxedo, Niveus, The Favourite, Pink Favourite, Miss Wilcox, Madame R. Oberthur, Heston White, Framfield Pink, Golden Butterfly, Dr. Enguehard, December Pink, December Gold, December Bronze, Cream Favourite, Baldock's Crimson, Burton Avalanche, (incurving form), Nagoya, Christmas White, Balcombe Beauty, Terra Cotta, Ruby Jones, and Pride of Ryecroft. The above include all the colours you mention. In case you have difficulty in getting them all, a few additional ones are Winter Glow, Winter Gem, White Queen of the Exe, Salmon Cheer, Western King, Mayfield Sunrise, Madame E. Roger (green), and Mrs. J. Thompson.

Edging for Path. *O. D.* Good evergreen edgings for paths are Armeria maritima (Thrift), a single or double line of crowns of London Pride, and Cerastium tomentosum. The last may be prevented from flowering, if you wish, by clipping the stems short in April with the garden shears. The edge may also be cut straight by laying the garden line and using the edging iron. An uncommon edging may be had by planting bulbs of Zephyranthes candida in autumn. It flowers freely in early autumn, the blooms being white.

Flowering Plants for a North Wall. *J. P.* The most suitable flowering shrubs to train against a north wall are the white-flowered Jasminum officinale, the yellow J. nudiflorum, and the double yellow Kerria japonica flore pleno. Crataegus Pyracantha Lalandei is the best evergreen for a north wall, but it does not fruit well there, though it grows well. Roses for that aspect are Felicité-et-Perpétue, Gloire de Dijon, Bouquet d'Or, and Alberic Barbier.

Paint for Vine Rods.—*J. D.* It was an old custom to paint vine rods with something after they had been washed or cleansed; but the best growers came to see that the paint was of doubtful value, and even made hiding places for insects during summer as the paint began to flake off. We have known vine rods to be painted over with tar, but those vines had to be replaced by young ones a few years afterwards. The common and less drastic paint of olden times was made by stirring strong clay or brick earth into a pail of water till it acquired the consistency of paint. Some lime and soot were also stirred into the mixture with a handful or two of flowers of sulphur. Two or more ounces of Gishurst Compound or soft soap were dissolved in boiling water, added to the mixture and stirred. A better plan is to rely upon the washing, and in summer when tying down the vines, thinning the berries, etc., to have handy a bottle of methylated spirit and a brush to treat each mealy bug with the spirit. The pest may be exterminated by this method if a close watch is kept on the vines for a summer or two.

Vines and Mealy Bug. *J. D.* The vines should first be pruned and the prunings burnt. Next, wash thoroughly the interior of the glass and woodwork with strong, soapy water. The back wall of the vinery should then be whitewashed or limewashed. In the latter case, the wash should be made with quick lime (builder's lime), which is stirred into a pail of water till it becomes thick enough. The loose bark of the vine rods should be rubbed off by grasping them tightly in the palm of the hand, and working them round, first one way and then the other. Next, dissolve three or four ounces of Gishurst Compound or soft soap to the gallon of boiling water. If the soap is used, the specific is improved by adding a handful of flowers of sulphur to the gallon. With a half-worn or stiff painter's brush, rub the solution well into the bark of the rods, especially about the spurs, taking care not to injure the buds.

Wash for Fruit Trees.—*P. D.* Common salt at the rate of half-a-pound to the gallon of water has been used for destroying moss and lichens on fruit trees, by spraying them with the solution in January or February. Milk of lime has also been used for the purpose. Quick-lime is first slaked with a little water by laying it in a heap on some boards, or any hard surface. Any lumps remaining may be gathered in a heap and wetted again. Stir the powdered lime into a pail of water till it forms a thick cream, which should be filtered into another vessel, and then applied to the trees with a syringe. The caustic spray is a very efficient one, however, and if you select a still day and walk on the side of the trees from which the wind is blowing, it should be possible to carry out the spraying without injury to the operator.

Weedkillers and Grass. *J. P. O'D.* Weeds in the pavements of courtyards may be destroyed by dusting them well with common or table salt in dry weather, from March to May inclusive. The point is to select a dry period, so that the salt may not be diluted and carried away by rain before it has had time to act. Agricultural salt would be cheaper, but would require to be pounded up rather finely before use. Finely powdered sulphate of ammonia would answer the same purpose.

Pigeons and Spring Cabbage. *J.* We have only been troubled with wood pigeons in one garden, and had recourse to shooting them. They were troublesome to Gooseberries, Cauliflowers, and Peas, in the quiet and less frequented parts of a large garden. The Peas were staked and that protected them considerably. The pigeons were very wild, so the best marksman went round the outside of the garden walls while another proceeded to rouse the pigeons from inside. At the present time, as there are less facilities for shooting, it would be well to dissolve some soft soap in boiling water and stir some soot and lime in to make it distasteful to the pigeons. Young Cabbages, Broccoli, etc., could be sprayed with the mixture. This should not be applied to hearted Cabbages or Broccoli coming into use, but we have never known pigeons to attack such plants in summer, except when the latter were quite young.

242,371. Swingler, E.—Lawn (or the like) rollers.

242,360.—Healy, J.—Garden shears.

Printed copies of the full published specifications may be obtained from the Patent Office, 25, Southampton Buildings, W.C.2., at the uniform price of 1/- each.

Abstract Published.

New Lawn Mower. *Patent No.* 240,915.

A new grass cutter having oscillating cutting blades working similar to a reaping machine, has been invented by Mr. H. A. T. Stoakes, of Brendon Cottage, Pinley, Claverdon, near Warwick. The oscillating blades co-act with a fixed horizontal blade having a front cutting edge. The blades are double-acting and are curved so as to have a cutting action like shears and scythes: a scraper keeps clear the gap between the rollers. Rotary vanes are provided to sweep the cut grass into a collecting box. The machine is provided with propelling or guiding handles and provision is made for the attachment of a driving motor.

THE LATEST TRADE MARKS.

This list of Trade marks of interest to readers has been selected from the *Official Trade Marks Journal* and is published by permission of the Controller of His Majesty's Stationery Office.

460,583.—Seal device bearing monogram of of letters P Q and headed with the words PEDIGREE--QUALITY, for seeds for agricultural and horticultural purposes.—Sutton & Sons, 10, Market Place, Reading, Berkshire. November 25, 1925.

LABRISOL.

463,243.—Chemical substances used for agricultural and horticultural purposes.—Brisbane Laboratories, Ltd., 15a, Brisbane Street, Camberwell Green, London, S.E. 5. December 2, 1925.

APPETONIC.

463,319.—Chemical substances used for agricultural and horticultural purposes.—W. G. Kelynack, 5, Station Road, Heathfield, Sussex. November 25, 1925.

Readers requiring information and advice respecting Patents, Trade Marks or Designs should apply to Messrs. Rayner and Co., Patent Agents, of 5, Chancery Lane, London, W.C. 2, who will give free advice to readers mentioning this paper.

REMARKS. Daffodils have been fairly plentiful during the past week; in addition to larger supplies from home growers, small consignments have been received from Guernsey. Narcissus Grand Primo and N. Soliel d'Or are to be had in excellent condition. The Tulips are excellent, including a good selection of single varieties, such as La Reine, Yellow Prince, Thomas Moore, Camoise Brilliant, Gris de Lin, Wm. Copland and Rosina. The double varieties, Couronne d'Or, Murillo and Double White are also fine; large supplies of these blooms are also being received from Holland. More Snowdrops are available, and the first consignment of Primroses has been on sale. Lilium longiflorum, L. speciosum (lancifolium) rubrum and Richardias (Arum) are becoming more plentiful again: the severe weather checked the supply of Arums during last week, and the small consignments were sold very quickly. Camellias, Freesias, Hyacinths and single Violet Princess of Wales are arriving in large quantities. Supplies from the south of France have been checked by the severe weather. Anemones, Marguerites, Ranunculus and Violets have been most affected but they are gradually reappearing, and prices are more normal. Flowering plants are receiving most attention from buyers. These include Daffodils, Cinerarias, Hyacinths, Genistas, Azaleas, Cyclamens, a few Ericas and Chrysanthemums. A few Paul Crampel and West Brighton Gem Pelargoniums in forty-eight pots were on sale last week. Ferns and Palms are somewhat limited in quantity as growers are sending small supplies.

REMARKS. Business has been fairly active for the time of year, and a steady volume of produce has been handled. Shipments of fruits from South Africa are more numerous each succeeding week, and consist mainly of Peaches, Nectarines, Pears and Plums. The demand for these fruits is moderately good. The enquiry for Apples is, on the whole, quiet. The comparatively few first-grade English Apples are selling better than imported Apples. Hothouse Grapes are meeting a good demand; both English and Belgian Grapes are not plentiful. Some good Grape Fruits are available and seem to be in better request, with the result that quotations are a shade firmer. The Banana trade remains unchanged, the prices showing little or no fluctuation. Oranges are a quiet market with no alteration in prices. French Beans are scarce and costly. Asparagus has recovered from its recent period of slumpy prices, and both English forced and imported Asparagus are a much better trade. New Potatos are meeting a fair demand, and new Potatos from the Azores are also a little more popular, but those from the Canary Islands and Algeria have shown no such relative improvement. French Beans from Madeira reached the market in variable condition, but they sold moderately well. The growers in the Worthing district are sending a larger number of Cucumbers, and the recent high prices have receded somewhat. Cauliflowers, mainly from France and Cornwall have sold well and should continue to be in demand at prices satisfactory to the producers. Lettuces and other salads from France are selling at comparatively high prices, in spite of the fact that quantities seem larger than usual. Mushrooms are meeting a good market, and although fancy prices are not being realised the demand is steady and regular. Paris has recommenced sending and this may have the effect of slightly easing the market. Tomatos from the Canary Islands are on the short side and their prices have risen. The trade in forced Rhubarb has been very poor at anything like good prices. Green vegetables continue to sell well, Brussels Sprouts in particular. The trade in old Potatos remains stable, with good sorts in demand.

GLASGOW.

There were fewer cut flowers in the market during the past week, and as the daily supplies approximated to the demand, prices remained steady with a firming tendency in places. Tulips dominated the sales, and the wider range of varieties included several Darwins. Bartagon was worth from 2/3 to 2/6 per bunch of 6; William Pitt, 2/- to 2/6; W. Copland, 1/- to 1/5; Rosina and Rose Tendre, 1/3 to 1/8; Couronne d'or, 1/2 to 1/8; seconds realised 1/-; Flamingo and Murillo, 1/2 to 1/6; Prince of Austria, 1/- to 1/4; Vermilion Brilliant, 1/- to 1/3; Thomas Moore, 9d. to 1/-; and La Reine, 8d. to 1/-. The few Chrysanthemums offered consisted of Western King and Heston White, the former making 1/- to 1/6, and the latter 6d. to 10d. per bunch. Narcissus made 18/- to 20/- per pad; Lilac, 5/- to 7/- per doz; Lily-of-the-Valley was cheaper at 1/3 to 1/6 per bunch; White Hyacinths, 7d. to 8d.; specials, 1/- to 1/3; blue and pink, 10d. to 1/-; Carnations were dearer at 6/- to 8/- per doz. There was a glut of Mimosa which realised 3/- to 5/- per pad until Friday, when the price recovered to 6/- and 8/-. Daffodils sold at 8d. to 1/- for Scotch Golden Spur; Spalding-grown blooms, 10d. to 1/1; and Ornatus, 10d. to 1/-.

In the fruit market a good business was done in bitter Oranges at 13/3 for Seville brands, and 10/6 for Palermo. Jaffa Oranges advanced 1/6 per case to 13/6, but Valencia fruit continued in favour of buyers. Counts of 300, 360, and 504 ranged from 6/- to 10/6; 420 and 714, 10/- to 15/-; and extra large, 16/- to 20/-. Mandarins made 9d. to 1/- per tray. Palermo Lemons, 12/- to 13/6. Grape Fruit, 22/- to 30/-. American Apples were in steady demand at the following quotations: British Columbia — Delicious 13/6 to 16/6 per case; Spitzbergen, 11/6 to 13/-; Jonathan, 10/- to 12/-; Grime's Golden, 9/- to 11/6; Oregon — Newtowns, 16/- to 19/-; Spitzbergen, 12/6 to 14/-; Canadian Baldwin, 22/- to 25/- per barrel; Greenings, 28/- to 32/-; Virginia York Imperial, 32/- to 34/-; Gano, 16/- to 19/-; Ben Davis, 12/6 to 15/-; New York State Greenings, 26/- to 30/-; Ben Davis, 12/- to 15/-. Nova Scotia Baldwin, 10/- to 15/- and Golden Russet, 16/- to 32/-; Winter Nelis Pears, Californian, 22/- to 25/- per case; Oregon, 14/- to 18/-; Washington, 8/- to 12/-. South African Peaches, 7/- to 8/- per tray; Clapp's Favourite Pears and Plums, 6/- to 7/-. Rhubarb made 40/- to 42/- per cwt.

Case Onions were the feature of the vegetable section, 5's being worth 11/- per case, and 4's, 8/6. Seakale fluctuated between 2/6 and 2/9; Spruce, 1/6; Endive, 3/- to 4/-; Lettuce, 1/3 to 1/6; French out-door Lettuces, 2/6 to 3/-; French Beans, 6/- to 7/-; Artichokes, 3/-; Flagelettes, 1/6, and Teneriffe Tomatos, 24/- to 30/-.

GARDENING APPOINTMENT.

Mr. W. Stephenson, for twenty-one years Gardener to the late SIR EDWARD PEARSON, Brickendonbury, Hertford, as Gardener to SIR WALTER LAWRENCE, Hyde Hall Garden, Sawbridgeworth, Hertfordshire. (Thanks for 2/- for R.G.O.F. Box. EDS.).

SOME INTERESTING POTATO FACTS.

AMONG the many well-known varieties of Potatoes, including Majestic and Up-to-Date, raised by the late Mr. Archibald Findlay, of Auchtermuchty, is one which is well worth a trial. This is CATRIONA, an immune variety with a distinctive purple patch at the rose end of the tubers around the eyes. In season it is about the same time as Eclipse, and has the same habit of continuing growth, should it not be needed as soon as it is first ready for lifting. If well-sprouted, it will come in nearly as early as Sharpe's Express, and the quality, especially when lifted as soon as ready, is of the finest. It is also an excellent cropper, and one of the finest varieties for exhibition.

At the same time as he raised this, Mr. Findlay raised a number of other purple-eyed varieties and, unfortunately, after his death there was some confusion as to exactly which was the true Catriona. Our stocks won most of the leading prizes at the National Potato Show in 1925, and first prize at York Potato Show in 1926, among numerous others. We have supplied this stock to many merchants up and down the country, and those wishing to obtain the stock should make enquiries from their local seedsman, and failing being able to obtain it from them, we shall be pleased to supply direct. — KENT & BRYDON, LTD., DARLINGTON.

My Garden Book

By John Weathers

The title expresses in three words what this book is intended to be—a work dealing with the Science and Practice of Gardening, which you can consult on *any* gardening question that may arise. Within its handsome covers will be found over 800 pages in which the author imparts to you all the practical advice, information and knowledge he has accumulated in more than FORTY YEARS EXPERIENCE. The glimpse of contents given hereunder will prove that the desired information will be *found* every time "MY GARDEN BOOK" is consulted.

Divided into six principal parts, "MY GARDEN BOOK" contains a calendar of operations showing exactly what you ought to do in flower, fruit, and vegetable garden during every month of the year, and a complete index directing you straight to the information you need to carry out the work.

CONTENTS OF "MY GARDEN BOOK."
INTRODUCTION. Where to Make a Garden—Walls, Fences, Shelters, Hedges—Clearing the Site for a Garden—Lawns, Bowling Greens, Tennis Courts—Garden Buildings and Appliances—Garden Implements—Garden Soils—Cultivation and Improvement of the Soil—Manures and their Uses—Plants and their Composition—How Plants Eat, Drink, and Sleep—Leaves and their work—Flowers and their Uses to Plants—Propagation of Plants—The Hardy Flower Garden—Introductory. The Mixed Herbaceous Border—Hardy Herbaceous Perennials—Hardy and Half-Hardy Annuals and Biennials—Hardy Bulbous Plants—Climbing and Trailing Plants—The Rock Garden—Water and Bog Gardening—Hardy Ferns—Ornamental Flowering Trees and Shrubs—Roses—Greenhouse and Conservatory—Plants suitable for Cultivation in the Green house, Conservatory, etc. The Hardy Fruit Garden—Pruning Fruit Trees—The Training of Fruit Trees—Spraying Fruit Trees—The Best Kinds of Fruits for British Gardens. The Vegetable or Kitchen Garden—Propagation of Vegetable Crops—Descriptions, Culture and Propagation of the Best Vegetables for British and Irish Gardens—The Herb Garden—Calendar of Work from January to December.

OVER 400 ILLUSTRATIONS; 24 IN FULL COLOUR.

"The Garden" says, "may be looked upon as an encyclopaedia of gardening confined within the limits of a single volume" and "The Field" is of opinion "should prove of the greatest value to the gardener whose aim is to make gardening profitable as well as ornamental". Even in private gardens to-day profit-making is all important, and the author of this work lays great stress upon it.

Mr. T. Lear, of Newcastle-on-Tyne, writes:—
"It is a glorious book, and fine value for money. Every page is fascinating, and every sentence beneficial. It is surely the acme of works of its kind."

NOW is the time to get the book! Not only will it give great aid in PLANTING but during the winter months you have the time to study how to improve next season's work.

Take the initiative NOW. Fill in this form. It commits you to nothing—and accept the book

The Royal Horticultural Society.

The Annual Report of the Council, summarising the activities of the Royal Horticultural Society during the past year, and setting forth the principal matters which the Council proposes to deal with in the present year, is before us, and will be presented to the Fellows at the Annual Meeting on Tuesday next at 3.30 p.m. in the Lecture Room. The Report makes the pleasing announcement that since the last annual general meeting the number of Fellows and Associates has increased by over one thousand. On November 18th, 1925, the membership was 21,878, which is, we believe, the largest in the history of the Society. The total income for the year amounted to £51,896 2s. 6d., and a balance of £27,517 19s. 11d. is shown on the general account; from this balance, however, has to be deducted the expenses of Wisley, amounting to nearly £10,000, and a sum of £16,000 placed to the reserve fund. Finally the balance sheet shows a balance carried forward of £1,105 9s. 7d. The Council very truly states that the Society has out-grown its home as a natural consequence of its continued prosperity; when the hall in Vincent Square was opened in 1904 the membership was only 8,360. The new hall, about which there has been so much speculation, is to be erected in Elverton Street, Westminster, almost adjoining the present building. The Council has obtained a lease of the site for a term of 999 years at a ground rental of £1,300, and the area available will accommodate an exhibition hall nearly twice as large as the existing one. During the present year the Council proposes to enter into contracts for the excavation of the site and the erection of the building. So far no estimate has been obtained as to its cost, but a design prepared by Messrs. Easton and Robertson, of 36, Bedford Square, W.C., has been accepted, subject to certain modifications. Mr. J. Murray Easton, A.R.I.B.A., a member of the firm of Messrs. Easton and Robertson, has arranged to deliver a lecture on the proposed new building on Wednesday, April 7, at which Mr. C. T. Musgrave, the Chairman of the Housing Committee, will preside, when we shall, doubtless, know some of the details. No further information on the new hall is given in the Report, but several particulars were published recently in one of the daily papers, although the information was not sent to the horticultural press, and, apparently, is not at present forthcoming for the Fellows. A full programme of shows was held during 1925, the least successful being the special Amateurs' Show, which is somewhat surprising and is excused on the grounds that hot, dry weather prevailed immediately preceding the show, and many who had entered found themselves unable to exhibit. The Society proposes to hold a similar show for amateurs on July 22, and it is to be hoped that this will be advertised better than the last. The special Vegetable Show held in conjunction with the fortnightly exhibition on September 8th last, was also not so good as usual, but in this connection we think some of the failure may be attributed to the inadequate prizes offered in the various classes, compared with the big provincial shows; exhibiting is now a very expensive matter, and unless rewards commensurate with the trouble and outlay are offered the response will always be poor. No reference is made to the shows of the special floricultural societies which were held in the Horticultural Hall last year, but these, even more than the Society's own exhibitions, proved the inadequacy of the building for the purposes of holding important horticultural shows in the metropolis. Although the proposed new building will, as stated, have double the floor space of the old hall, the exhibitions of such Societies as the National Rose Society, the National Chrysanthemum Society and the National Sweet Pea Society, will, judging by those of recent years, be of sufficient size to fill all the available space. The R.H.S. has in these separate organisations valuable allies in the advancement of horticulture, and as Fellows are admitted free to the exhibitions provided by these several societies, some recognition of the Council's indebtedness would not have been out of place, especially as the Council receives payment for the use of the hall on those occasions. The reference to Wisley states that the Gardens are visited by Fellows in increasing numbers every year. The Sunday opening has not proved such a success as many expected, but the experiment will be repeated this year, when the Gardens will be open each Sunday from May 2 to October 10, between the hours of 2 p.m. and 6 p.m. The appointment of Mr. R. Findlay as Keeper of the Wisley Gardens is a step in the right direction, and it is hoped to appoint a principal officer as Keeper of the Laboratory in the near future. Further land has been prepared in Seven Acres and planted with shrubs and flowering trees, and amongst other alterations and improvements the collection of Rose species has been augmented; parts of the garden have been replanted, three acres to form a shelter belt along the whole west end of the garden having been purchased, fenced, and for the most part planted with trees. Amongst the experimental work carried out at Wisley the experiments on green manuring have been continued by Dr. Darbishire, who has also made investigations into the composition of varieties of Potatos and, in connection with Mr. Buxton, in the colours of flowers, especially Primroses. The experiments of pollinating in orchards and certain aspects of summer pruning have been continued by Mr. Rawes, while Mr. Dowson has in hand investigations on the Stem Rot of Carnations; sclerotial diseases of bulbs, of Antirrhinums, etc., the Die-back disease of Roses and Rubi, and a Core-rot disease of Apples. The Society has established four scholarships for young men from private gardens and nurseries, carrying a maintenance allowance of 35s. a week and tenable at the Society gardens. Two of these scholarships are available for 1926. An important appointment has been made during the past year, that of Mr. Walter M. Epps, F.R.I.B.A., as Surveyor to the Society, who will regularly inspect all buildings in which the Society has an interest and supervise all repairs. Amongst the more interesting of the awards made last year are those of the Veitch Memorial Trust Gold Medal to Mr. E. H. Wilson, V.M.H., for his introductions to gardens and his books; and to Mr. W. P. Thomson, for his journalistic work in connection with horticulture. Mr. Thomson has been a prominent figure in horticulture for a large number of years and the award is well merited; we offer him on behalf of ourselves and our colleagues of the horticultural press sincere congratulations. A Gold Medal will be offered to the amateur who stages the best exhibit of alpines in pots at the fortnightly meeting of March 23. It is a sad circumstance that two of the gentlemen elected to vacancies in the list of holders of the Victoria Medal of Honour, Mr. S. B. Dicks and Mr. W. R. Dykes, have passed away before the actual presentations of the medals were made. An appreciation of the late secretary is included in the *Book of Arrangements*, where it is stated that he devoted his remarkable abilities to the maintenance of the Society. The concluding paragraph of the Report voices the thanks of the Council to the members of the Society's staff, and we also tender our thanks to Mr. Frank Reader and his colleagues for the courtesy and help given, not only during 1925, but over very many years.

Royal Gardeners' Orphan Fund.—We would remind subscribers to the above horticultural charity that the Annual General Meeting will be held at "Simpson's" 101, Strand, London, W.C., on Wednesday next at 2 p.m. We learn with great pleasure that Her Majesty the Queen has graciously consented to become Patron of the Fund in succession to the late Queen Alexandra.

The Conservation of the Nation's Vegetation.—This is the title of a brochure by Mr. R. W. Ascroft, for some time Assistant Secretary of the Royal Horticultural Society. The purpose of the book is, obviously, to show the damage done to vegetation by smoke and to advocate the use of gas for heating, lighting and cooking purposes instead of coal. Mr. Ascroft states that the greatest amount of damage is done to vegetation through the sulphurous acids which enter the leaves through the stomata, and he gives figures showing the increase in the amount of this acid present in the atmosphere during a fog. Incidentally, he remarks that the cost of washing the glasshouses at Kew Gardens after a fog amounts to approximately £100. Dr. W. J. Russell computed that in Manchester so much as one-and-a-half hundredweight of sulphuric acid was deposited per square mile of surface during dense fogs. Almost equally injurious are deposits of tarry matter from domestic smoke, for in this tarry matter are such substances as pyridine and phenol, both of which are of an exceedingly poisonous nature in so far as plants are concerned. It is stated that the former substance is possibly responsible for the yellow discoloration which takes place in many flowers which have been exposed to fog.

Moscow Botanic Garden.—Mr. George Trespe, Curator of the Botanic Garden, Moscow, celebrated last month the twenty-fifth anniversary of his appointment. He was born in Riga in 1868. He was formerly for twelve years with a nursery firm in Moscow, where he finally became head of the seed control department before obtaining the Curatorship of the Botanic Garden.

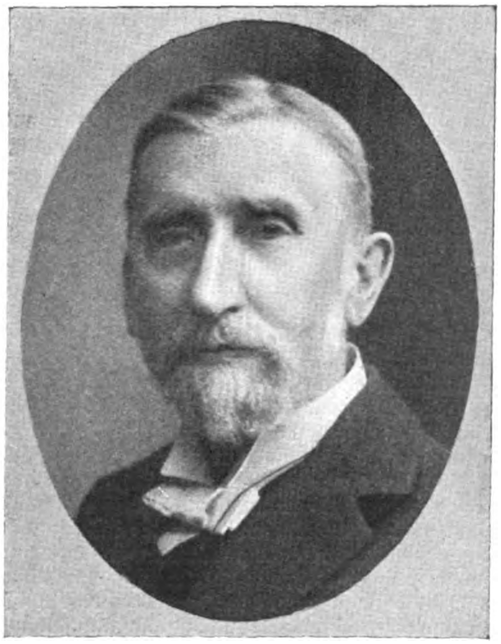
Plants in Flower in the Public Gardens, Nice.—Mr. S. J. Mackenzie informs us that at present Cyclamens, Cinerarias, Violas, Primula sinensis and Carnations are the chief flowering plants in bloom in the public gardens at Nice. Cyclamens are used extensively, 16,000 to 17,000 plants being raised annually to meet the requirements of the gardens and open spaces. Seeds are sown in August to produce flowering plants sixteen or eighteen months later. Primula sinensis and Cineraria grandiflora are also employed extensively as bedding plants. In the Jardin Albert Ivy-leaved Pelargoniums clothe the trunks of the Palms and are now in bloom in sheltered places. Palms are well represented by both pinnate and palmate leaved types, and there are some fine specimens to be seen in the Jardin Albert. Having a natural protection from the north, Nice enjoys a very mild climate; the mean winter temperature is 50°.

Forthcoming French Congresses.—The Féderation Horticole Professionelle Internationale is holding a reunion in Paris on February 13, beginning at 9 a.m. The proceedings, which will take place at the offices of the French National Horticultural Society, Rue de Grenelle, will include discussions on the American prohibition of bulb imports, the general question of customs duties and other relevant matters. It is almost decided that the eighteenth annual congress of the Federation of French Horticultural Societies shall be held at Rheims during the first fortnight of July, probably from the 5th to the 7th inclusive. The twenty-sixth Congress of the Société Française de Chrysanthémistés has been arranged to take place at Blois, from the 4th to the 7th of November, 1926. The proceedings will include an exhibition and several excursions to places of local interest, besides the usual discussions.

National Rose Society's Show at Southport.—The National Rose Society will hold its Jubilee Provincial Show at Southport in conjunction with the Southport Floral Fête, on August 25th, 26th and 27th. The Society's Schedule for this exhibition contains twenty-two classes, and the cash prizes offered amount to £260 10s. 0d. A novel arrangement in connection with the trade classes is provided by the division of the country into two geographical districts, *i.e.*, north and south of an imaginary line drawn from Spalding to Aberystwyth. The nurserymen north of this line, or in Ireland, will compete together, and those south of the line will compete with each other.

Sugar Beet Cultivation in Scotland.—According to the annual crop returns issued by the Board of Agriculture, Sugar Beet was grown on approximately 1,500 acres in 1925, as compared with 200 acres in the previous year. The crop, generally, is reported to have done well, except in parts of Bute and Stirling, where the sowings were failures, and the land was afterwards resown with other crops. In the eastern and northern districts, the yield ranged from six to twelve tons per acre, while on one farm in Forfarshire the weight is estimated at fifteen tons per acre. Snowstorms at first delayed the lifting of some of the crops, and while the condition of the crops is uncertain, the consignments sent to the factory have given from sixteen to nineteen per cent. of sugar. The handsome Silver Cup given by Mr. John McNiel, Glasgow, through the Kintyre Agricultural Society, for Sugar Beet grown in Kintyre containing the greatest weight of sugar, has been won by Mr. Alex Mitchell, Aros Farm, Campbeltown.

Rev. F. Page-Roberts.—It is with great pleasure we publish the portrait of the doyen of Rose growers, the Rev. F. Page-Roberts, whose genial wit, warm-heartedness and wide knowledge of Roses and rosarians have endeared him to all. Many rosarians have been such "from their youth up," but the Rev. Page-Roberts did not commence Rose growing until he went to Scole, in 1875, when he had as garden helper a village woman who "smoked a honest clay pipe, but not in public, to be seen of men." Although he did not know one variety by name when he began to cultivate Roses, he made good use of his opportunities and became successful, continuing his successes over a long period of years. In years long past, he and the Rev. Foster-Melliar were keen rivals, and on one occasion he set up his own and his rival's Tea Roses and equal first prizes were awarded! As a rule, the Rev. Page-Roberts was the better exhibitor—though not always the better grower—as he had a peculiarly happy and clever way of setting-up his blooms. For some time he lived at Halstead in Kent, and then moved to Strathfieldsaye Rectory, where he made a charming garden in which Roses became a fine feature. In recognition of his services to the National Rose Society that body elected the Rev. Page-Roberts as its President in 1909, an office he also held in the succeeding year, to the great delight of all who worked with him. For many years he was chairman of the Society's New Seedling Rose Committee, and in 1919 he was awarded the Dean Hole Memorial Medal. Nor must we forget his able services as a florist on the Floral Committee of the Royal Horticultural Society, and his remarkable ability as a judge of Roses, but he is probably best known for his "loving kindness" to all, and his "tender mercy" to novices. After a long life of usefulness, the Rev. Page-Roberts has retired from the living at Strathfieldsaye, and is now residing at Stratfield Sturgis, Basingstoke, where his many friends hope he will enjoy rest and health and strength—and Roses—for many years to come.



REV. F. PAGE-ROBERTS.

Gift to West of Scotland Agricultural College.—Some time ago, Mr. John Hannah, Girvan Mains, a prominent Ayrshire farmer and a successful raiser of early Potatos, purchased the estate of Auchencruive, situated a few miles inland from Ayr, and he has now offered, under certain conditions, to present the mansion house, policies and 400 acres of arable land to the West of Scotland Agricultural College for the purposes of a dairy school and experimental farm. It is understood that one of the conditions provides that a college shall be built at Auchencruive, and the various departments centralised in that building. This would involve the transference of the headquarters from Glasgow, and the Directors are considering this munificent offer as it affects the dairy school at Kilmarnock, for the lease of the Holms farm has expired, and they have been unable to come to terms respecting its purchase.

Presentation to Mr. R. F. Felton.—On the occasion of Messrs. Felton and Sons' (Hanover Square) Staff Ball, Mr. R. Forester Felton was presented with a handsome gold cigarette case inscribed, "To the dear old chief, from all at Hanover Square, some who have left and a few Covent Garden friends." Many relations and friends of the staff were present at the function, at the Adelphi Rooms, Edgware Road, A very pleasant evening was spent, and Mr. Felton, in acknowledging the presentation, spoke very highly of the loyalty of his staff.

A New Hybrid Cupressus.—In a communication to the Linnean Society, Mr. A. Bruce Jackson discusses a new hybrid Conifer, Cupressus macrocarpa × C. nootkatensis. It appears that a branch of a Cypress was received at Kew from Capt. Naylor, Leighton Hall, near Welshpool, and this excited considerable attention because it combined the characters of the two species named. The tree was raised in 1911 from seeds of a cone taken from a tree of C. macrocarpa growing about twenty yards from a specimen of C. nootkatensis which was evidently the pollinating plant. Capt. Naylor stated that a much earlier mating of these species occurred at Leighton in 1888, when his uncle, Mr. Leyland, raised the same hybrid from a tree of C. nootkatensis, the male parent being in this case the same tree of C. macrocarpa which took part in the reciprocal cross twenty-three years later. There appears to be no previous record of a hybrid in the genus Cupressus.

Daphne Laureola.—Miss K. M. Hinchliffe, Instow, who sends a few flowering branches of Daphne Laureola, reminds us that the present is a good time for readers to examine their plants of this early-flowering shrub with a view to ascertaining the fragrance and periodicity of fragrance of its green flowers. Readers will remember that a great deal of correspondence on this subject appeared in our pages during the spring of 1925, and it was suggested that correspondents should begin to examine their plants of this species in January, write down the dates of examination, time of day, weather, scent (or not) out-of-doors, fragrance when gathered and brought indoors, and do this every week or ten days for so long as the plant is in bloom, and finally send us their observations. We may add that the specimens from Instow arrived just as we were going to press, and when the box was opened certain members of our staff could detect a very little fragrance, while others failed to do so.

What are Flowering Plants?—The Linnaean Society, on Thursday, January 21st, was the scene of an interesting discussion which would have greatly puzzled earlier generations of botanists. At a big meeting most of the senior professors of the day were present to discuss the question as to whether a certain family of plants possessed carpels or not, and even diverged into a discussion as to what carpels are. Needless to say, the basis of this discussion was not a living family of plants, but an extinct group—that discovered and worked out in such careful detail from such unpromising fragments by Dr. H. H. Thomas and christened by him the Caytoniales. The plants are Jurassic in age and appear to have borne branches on which were placed small structures, each of which can be compared to some extent with a carpel containing several seeds. To some extent the plants seem to have been like the Pteridosperms, the Bennettitales, and even to have had foliage which had hitherto been considered that of Ferns. The origin of the flowering plants—now the dominant group of vegetation—has always been, since Darwin's time when people began to think about it, "an abominable mystery." As Angiospermic timbers have been discovered in the latest Cretaceous strata, it is reasonable to suppose that some form of Angiosperms existed in the Jurassic period. But, though the greatest minds were devoted to the discussion the other evening whether the Caytoniales could claim the distinction of being primitive Angiosperms or not, was left undecided. To the modern gardener who deals with plants about which there can be no doubt as to the group to which they belong, such a discussion gives a peep into a world of mystery and romance, and indicates that, although living plants are so established in their major differences, there was a time when the groups now dominating gardens had not differentiated even the main organs we know.

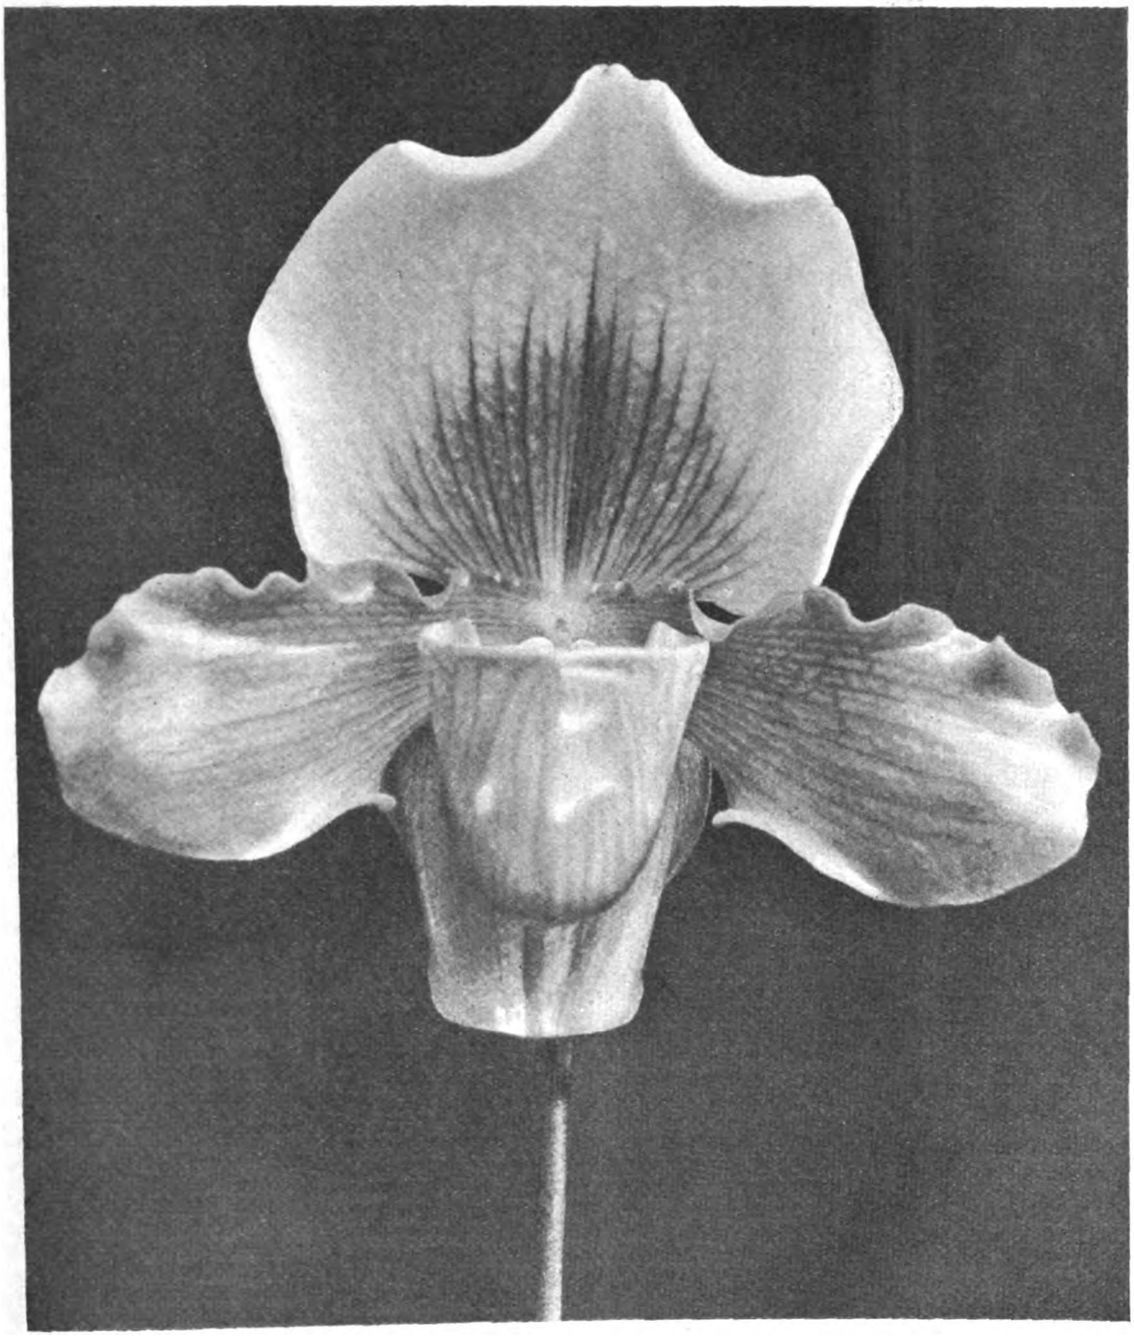


FIG. 47.—CYPRIPEDIUM SIR TREVOR.

R.H.S. First Class Certificate, January 26. Flowers green, yellow-green and white. Shown by G. F. Moore, Esq., Chardwar, Bourton-on-the-Water (see p. 88).

Appointments for the Ensuing Week.—Sunday, February 7: Wakefield and North of England Tulip Society's Meeting. Monday, February 8: United Horticultural Benefit and Provident Society's meeting. Tuesday, February 9: Royal Horticultural Society's Committees meet and annual meeting; Jersey Gardeners' Society's meeting. Wednesday, February 10: Royal Gardeners' Orphan Fund annual meeting and election at Simpson's, Strand; Glasgow and West of Scotland Horticultural Society's lecture; Wimbledon Gardeners' Society's meeting. Friday, February 12: Royal Horticultural Society of Ireland Council meeting; Orchid Club meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Timber Preserving.*—At the back of the house, No. 22, Essex Street, Strand, a rail of Oak was, in the year 1771, placed round a flat roof of lead, at a height of perhaps ninety feet above high water in the Thames. The rail was composed of an upper and an under bar, each of them might have been about four inches in the square, the upper bar rounded off as a handrail; into these bars were morticed uprights of about two-and-a-half inches square. Robert Mylne (the architect of Blackfriars Bridge) directed that the whole rail should be left without paint or any other coating for two or three years, to season; it, however, never was either painted or coated in any way between that time and the year 1800, a period of nearly thirty years, and yet it was as sound at the end of it as when first put up. How long afterwards the rail lasted is not known. *M.* The remarks which have lately appeared on this subject, remind me of the following conversation. Walking one day with the late Mr. Atkinson, of Silvermere, in his grounds near a lake, where he had recently built a summerhouse of home-grown wood, I asked him whether he did not mean to give it a coating of something to preserve the timber? He said, "No." Would not brushing it over with linseed oil be a good precaution, without altering its appearance? "No; I think all such applications more calculated to induce decay," or words to that effect. He did not enter into the *modus operandi* of the application, nor did I ask him, but such was his opinion. When on this subject, I may mention an instance of durability in naked wood that, some years ago, fell under my own observation. Being engaged in alterations in a garden of which I had charge, it became necessary to remove an old frame-ground, surrounded by a Reed-fence, six feet high. The rails of the old frame were of Cherry tree, cut triangularly and fixed to Oak posts. These rails were never either pitched, tarred, nor painted. When taken down, they were crusted over with a brittle crust about one-sixteenth of-an-inch deep, and all besides was sound and hard as bone; an old man who had worked in the garden between forty and fifty years told me that these rails had been there ever since he had been, and to his knowledge had worn out two sets of Oak posts. Again, I have frequently known green poles of Willow, peeled and used as fencing rails, to last many years, and attain a sort of toughness and durability from exposure, that any one at first thought would hardly expect; and even Ash poles, split and peeled, will last many years; the action of the weather on the outer surface raises a sort of short woolly covering that wards off the rain. So far, my observation coincides with some of the remarks of your correspondents on this subject. *Quercus, Gard. Chron., February* 8, 1851.

The Week's Work.

THE ORCHID HOUSES.

By J. Collier, Gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

Coelogyne Mooreana.—This Orchid blooms at this season and is deserving of inclusion in every Orchid collection. It is quite easy to cultivate, and grows well when suspended from the roof-rafters in a light position in the cool Odontoglossum house. Its upright spikes of white and yellow flowers are very lovely, and they last a long time in good condition. The best time for re-potting is soon after the flowers have faded. This Orchid should be afforded plenty of water at the roots during its growing season, but at all other times should be kept only moderately moist. Plants of Coelogyne cristata that have their flower spikes well advanced should not be allowed to suffer from want of water at the roots; moisture, however, should not be allowed to accumulate in the young growths or the flower scapes will probably decay.

Mexican Laelias.—These Orchids, which embrace Laelia anceps, L. autumnalis, L. Gouldiana and L. furfuracea, have been blooming for some time past, and as the flowers fade and the flower scapes are removed, the plants should be given attention in respect of re-potting or re-surfacing so soon as new roots are observed to be pushing from the bases of the last made pseudo-bulbs. Any plants occupying receptacles sufficiently large to accommodate another season's growth need not be disturbed, but where the old compost has become decayed it should be picked away by means of a pointed stick, the dusty particles washed out so that the drainage may be cleaned and made perfect, and fresh materials added. Coarse Osmunda-fibre, broken up rather roughly, with the dusty particles shaken away, forms a suitable medium. This should be pressed firmly around the base of the rhizomes of the plants. Specimens that have outgrown their receptacles may, if they have numerous pseudo-bulbs behind the leading growth, be broken up and made up afresh into shapely plants; retain two or three pseudo-bulbs behind each lead, and, in re-potting, keep the base of the plants just level with the rim of the receptacle. A few pieces of crocks inserted here and there in the compost will assist the free passage of water, which is always necessary for these plants. After root disturbance, water should be afforded very sparingly but the plant's surroundings should be kept moist in order to encourage root activity. The plants will grow equally well either in shallow Orchid pans or Teak-wood baskets.

FRUITS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Strawberries.—The plants of the earliest batch of Strawberries are growing freely and show every promise of producing good crops. The flowers will soon be expanded and at this stage the atmosphere of the house may be kept slightly drier, with a liberal supply of fresh air whenever the weather is favourable for ventilating the house. Although plenty of fresh air is recommended care should be exercised against cold draughts. I never pollinate the flowers of Strawberries growing indoors, neither do I think it necessary to do so, for in my experience the fruits grow to a better shape than those that have been pollinated with the softest brush. As the plants pass out of flower they may be afforded a slightly higher temperature if ripe berries are required at the earliest possible date, otherwise I recommend a temperature of 50° to 55° by night with a rise of 10° by day by solar heat. Far finer fruits and of better flavour are to be obtained by moderate forcing. The plants should receive some aid in the form of an approved fertiliser, which may be given in a diluted state on frequent occasions. Further batches of plants may be introduced into warmth as required, care being taken not to start them into growth in a high temperature.

Early Pot Peaches.—The earliest Peach trees in pots will now be in flower, and at this stage the atmosphere of the house may be kept slightly drier during the early part of the day, with a liberal supply of fresh air so that the pollen may become quite dry by noon, when the flowers should be gone over with a feather brush or rabbit's tail to distribute the pollen. When it is found that the fruits are swelling it will be wise to attend to the watering of the trees several times daily, especially on bright, sunny days, when a liberal supply of air is admitted to the house. Trees in pots should never suffer through lack of moisture at the roots, and if by chance the soil has been allowed to dry to such an extent as to come away from the receptacles, apply a top-dressing of fine soil and water the same thoroughly so that it fills up the space caused by over-evaporation. The work of disbudding will necessitate close attention; remove carefully all badly-placed growths, taking care to preserve the basal growths for future bearing. This operation is best performed at intervals to obviate causing a check to root action. Fumigate the house to keep the trees free from aphis and close the ventilators early in the day to make the fullest use of solar heat.

Orchard House.—Where all kinds of hardy fruits are grown under glass it is a wise plan to have trees in reserve in the open to replenish any that may have deteriorated. There is still time to arrange for planting reserve trees against outside walls, where they may be allowed to grow into good fruiting specimens. These, lifted carefully, will scarcely feel the effects of replanting; moreover, a certain amount of fruit may be taken from them the first season, thus insuring against failure of the crop caused by taking out unprofitable trees.

THE KITCHEN GARDEN.

By F. Streeter, late Gardener to Major Albert Pam, Wormley Bury, Broxbourne.

Herbs.—It is advisable to grow all herbs together on a west border, if possible. Trench the ground deeply, manure it freely, and slope it well to the front. If the soil is of a heavy texture use plenty of road scrapings and leaf-mould to lighten it. So soon as the ground has settled and is in good condition for planting, mark out the beds for each subject according to the demand. Another interesting method of planting is to arrange the border similar to the herbaceous border, and plant in groups, obviating a formal appearance by planting Lavender, Rosemary, etc. In the case of established borders, a good top-dressing of rich, sifted soil should be applied when pricking over and cleaning it for the coming season. Be careful not to bury Mint roots too deeply or this may cause the whole crop to rot off. Label the plants carefully and keep the border smart and clean thoroughut the summer.

Shallots.—So soon as the ground is in a suitable condition, plant Shallots. Rake the surface as level as possible and press the bulbs into the ground about two-thirds their depth, ten inches apart in rows made twelve inches asunder.

Leeks.—To obtain perfect specimens of Leeks, a long season of growth is necessary and a longer period of blanching. Therefore, an early start should be made with sowing the seeds. Prepare a number of clean, well-drained, sixty-sized pots and fill them to within an inch of the top with a compost of two-parts turfy loam, one-part well-decayed leaf-mould, and one-part coarse sand. Make the soil firm with the fingers, place three selected seeds near the centre of the pot, and cover them with similar compost. Place the seed-pots in a fruit house having a temperature of 55° at night. Keep the pots shaded with pieces of paper until the seeds germinate, when the seedlings should be exposed fully to the light to ensure sturdy, stiff growth. Water the seed pans with tepid water about forty-eight hours after sowing the seeds. Prizetaker and Improved Lyon are excellent varieties for present sowing.

Peas.—Make another sowing, in boxes, of an early maturing varity as advised in an earlier calendar. Keep the first sowing just germinated in cold frames protected from frost, but admit plenty of air on all suitable occasions.

PLANTS UNDER GLASS.

By John Coutts, Assistant Curator, Royal Botanic Gardens, Kew.

Asparagus.—Asparagus Sprengeri, A. plumosus and its varieties are indispensable for decorative work, either in the cut state or grown for mixing with floral arrangements. The seeds should be sown in a warm house; their germination will be hastened if they are soaked for twelve hours in warm water, and the seed pots plunged in a warm case provided with plenty of bottom heat. Asparagus Sprengeri is invaluable for filling hanging baskets, while for the same purpose the lighter and more graceful A. decumbens is even better suited. The young plants should be pricked off singly into small pots, and when large enough, may be transferred to baskets, or grown on in pots, according to requirements. A. medeoloides (syn. Myrsiphyllum asparagoides) generally known as Smilax, is largely used in the cut state for decorative work, and where required in quantity for this purpose, the young plants are best grown in a bed or border, training the long, slender shoots up thin string, care being taken to keep each one separate so that they may be cut readily as required. There is a small-leaved variety known as myrtifolius, which comes true from seed. A. Zutzii is an elegant new variety, which flowers very freely and should prove useful for decorative work. This variety is easily raised from seeds, as also is A. virigatus, which makes an elegant pot plant and is useful for the cool greenhouse. All the species and varieties of Asparagus are free-rooting subjects and enjoy an ample supply of water with liberal feeding at the roots.

Exacum affine.—Although a biennial this Exacum may be successfully treated as an annual and the seeds should be sown in a warm house at the present time. If exceptionally fine plants are required it is best to sow the seeds the previous September. Unlike E. macranthum, the successful cultivation of this species presents no difficulty. It naturally makes a neat, free-branching plant, and produces its small sweetly scented flowers with great freedom. It succeeds, generally, in a somewhat lower temperature than the other species.

Saintpaulia ionantha.—This beautiful Gesnerad, with its Violet-like flowers, is easily propagated at this time by means of seeds, or leaf-cuttings. The seeds should be sown in a temperature of 60°, while the leaf-cuttings will root in an open bed of fibre and sand. The plants are best grown in forty-eight-sized pots, or several may be placed together in a shallow pan.

HARDY FRUIT GARDEN.

By W. Auton, Gardener to Viscount Elveden, Pyrford Court, Woking, Surrey.

Morello Cherries.—This fruit is very serviceable during the late summer for use in tarts and confectionery, is excellent for bottling and highly valued for preserving in brandy. Although trees succeed as standards, they are generally trained on walls with a northern aspect, where they yield excellent crops. Owing to this position the buds are not excited into growth early in the season, and the pruning and training of the trees may be deferred until such work is completed with trees in sunny aspects. Morello Cherries are not so susceptible to the attacks of various pests as many other fruit trees, but it is a good practice to liberate all the branches annually, thoroughly cleanse them, spray the walls with a good insecticide, and, after removing all unnecessary wood, relay them at regular distances and make them secure by tying or nailing. When the work is completed, apply a good sprinkling of bone-meal and prick it into the surface of the border.

Figs.—Although the Fig grows freely in almost any good soil, it does not always fruit freely in rich ground, indeed, generally, the shoots are too soft and luxuriant to mature fruit unless the roots are given a decidedly restricted area. It is always wise to ensure this by building concrete receptacles for the trees when planting, as even if a hard road or path is in front of the border, the roots travel under it in course of time, and control is then impossible. Given a warm, airy position, exposed to sunshine and this restricted rooting area, their fruiting presents no great difficulty, and regular cropping may be relied on. Any necessary pruning and nailing should now receive attention, and, as the fruits, which in our climate attains maturity in the open air, are generally produced on the extremities of the previous year's growth, it is obvious that these must be retained in pruning. The present work thus consists in thinning the shoots where overcrowding is likely to occur, and securing the main branches to the wall. Where a large wall space has to be covered, a system of training should be established which enables alternate branches to be cut out each year, to allow room for the new wood to be laid in for subsequent fruiting. The Fig tree, grown as a standard, or bush, needs little pruning beyond the thinning of the wood to allow air and light to reach every part of the tree. When planting in positions away from a wall it is less easy to enclose a rooting area, and where concrete receptacles are not practicable, precautions should be taken to prevent the roots growing downwards. To ensure this, a good plan is to put a good layer of chalk at the bottom of the prepared positions. If this is well consolidated the roots will not go through it; moreover, in periods of drought, they are able to extract considerable moisture from it.

THE FLOWER GARDEN.

By F. C. PUDDLE, Gardener to LORD ABERCONWAY, Bodnant, Taly-Cafn, North Wales.

Alpines from Seeds.—The raising of alpine plants from seeds is not only one of the most interesting phases of rock gardening, but a ready means of increasing stocks, as many species may be raised with comparative ease. Seeds of Saxifraga, Sempervivum, Campanula, Wahlenbergia, Primula, Dianthus, etc., may be sown on a compost composed of loam, leaf-mould and coarse silver sand in equal parts. Gentiana verna, G. acaulis and the stronger-growing species require a slightly more loamy compost. No attempt should be made to hasten germination with heat; the pots may be placed in a cool frame, with a piece of glass over each pot to conserve the moisture. So soon as the seedlings are visible the covering should be removed and free ventilation given. If the seeds have been kept for any great length of time, germination may not take place for some months, therefore the pots should not be discarded too readily. Sooner or later, every enthusiastic grower of alpines feels that insatiable desire to grow the more difficult species of the higher altitudes, such as Androsace glacialis, A. helvetica, A. pyrenaica, A. imbricata and A. cylindrica, and the most difficult of all, Eritrichium nanum. These plants are very impatient of moisture round their crowns, or extremes of either drought or wet at the roots; they also resent a humid atmosphere. The seeds may be sown five or six in a well-drained three-inch pot, containing a mixture of one-part loam, one-part leaf-soil, and three parts coarse granite dust or silver sand. When the seedlings have formed small tufts, the pots should be plunged to the rim in larger ones containing sand, so that a circle of sand half-an-inch wide remains between the rims of the two pots. If this sand is kept moist it is rarely necessary to water the inner pot in which the plant is growing. The outer pot should be as well drained as the inner one, for the plants will eventually root into this, consequently the inner pot should not be moved or these roots will be broken. Span frames are best in which to grow these plants of the high Alps, as they may be more freely ventilated than those of the lean-to type; if these latter are used, it will be found a good plan to remove a board, or a few bricks at each end of the frame, level with the plants, so that a direct current of air passes immediately over them. A few plants may be tried in special places in the rock garden, but it will be found the safer plan to keep the majority of these difficult subjects always in frames.

Bedding Plants.—Standard and bush Fuchsias and Heliotropes intended for bedding should be pruned forthwith. The green tips of the Heliotropes may be used as cuttings; they will root readily if inserted in sandy soil in a warm, close case. If a further supply of cuttings is required, a few plants of both Heliotropes and Fuchsias may be introduced into a moderately warm house; but the main batch of plants should be grown gently on in a temperature of about 50°. Bedding Pelargoniums may now be potted and placed in a recently started vinery or Peach house. If the plants have not been stopped, it will be better to do this now and defer the potting for another fortnight; fairly hard stopping will secure a better break than mere pinching.

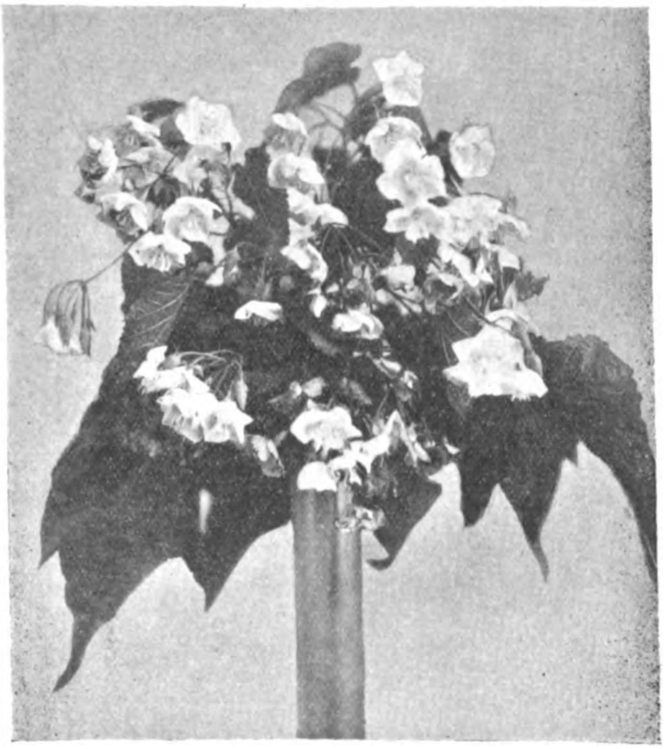

FIG. 48. DOMBEYA DAVAEI.

(see p. 99).

FOR NORTHERN GARDENERS.

By A. T. HARRISON, Gardener to the MARQUIS OF AILSA, Culzean Castle, Maybole, Ayrshire.

Bedding Plants.—Autumn-rooted cuttings of the various bedding plants including Pelargoniums (Geraniums) and Heliotropes should now be potted singly. Any deficiency in numbers may now be made good by inserting the required number of cuttings from stock plants. Cuttings of Pelargoniums root readily at this season if inserted around the edges of suitable sized pots, and do not damp off so freely as they do in autumn. They will provide useful small plants for setting out in June. The stock of Lobelia cardinalis, if wintered in a cool house, should now have the old flower stumps carefully removed, as these sometimes develop a fungus which decays the roots, and renders them useless. L. cardinalis may be increased readily now by division of the clumps, putting the divided portions into boxes filled with a compost containing plenty of leaf-mould.

Potato Planting.—A well-sheltered border, manured and dug some time previously, should be chosen for the earliest crop of Potatos. Fork the soil lightly, and when dry enough, open out the drills with a hoe or spade, allowing them to remain open for an hour or two if the day is warm. Place the sprouted sets carefully in the bottom of the drills, cover them and leave a ridge above the Potato sets. The extra covering will protect the growths from damage by frost, and keep the ground warm and dry. Some means of protecting the shoots from damage when they are showing through the ground should be at hand, and for this purpose Spruce branches on a light framework answer very well. This protection should be put in position every night when there is indication of frost and removed next morning. In this way it is possible to produce young Potatos early in May in our mild-weather districts, but for those inland, and in the eastern counties, at least a month later will be time enough to plant.

Pruning and Nailing of Fruit Trees.—Every favourable opportunity should be taken of proceeding with this work, as the sap is rising, but it is no economy or advantage to attempt it during cold or inclement weather, when some other operation such as digging or trenching should be undertaken. Young, vigorous fruit trees increase in thickness rapidly, and if not attended to in time the material by which they are tied will be found imbedded in the bark. The ties should all be removed annually and looser ones substituted, just sufficiently tight to ensure the branch or tree being kept in its proper position.

TREES AND SHRUBS.

RHODODENDRON SULPHUREUM.

RHODODENDRON "SULPHUREUM" as applied to the illustration in your issue of January 30 and referred to in the letterpress, is a misnomer. The plant is probably Cunningham's Sulphur; and if this be the case it is very doubtful if the parentage is R. caucasicum × R. arboreum album, since, although this is the pedigree given by Messrs. Cunningham and Fraser, there is no trace at all of the pollen parent. Mistakes sometimes occur in the records, as those of us who raise seedlings know; and I agree with Mr. Millais that this plant may be merely a good seedling from R. caucasicum var. stramineum. I am told, moreover, that it comes true from seed.

Seedlings raised from R. caucasicum var. stramineum × R. arboreum album show strong traces of R. arboreum in the leaf and closely resemble, even if they are not identical with, R. nobleanum album, which is supposed to be the reverse cross.

An altogether different plant has come to me also under the name of R. sulphureum, and is most likely a variety of R. campylocarpum. It has smaller leaves than the type, and smaller, more tubular flowers. For this the right name would appear to be campylocarpum var. sulphureum.

Now the name "sulfureum"—for this is the correct Latin spelling—rightly belongs to a Chinese species, which was discovered by Abbé Delavay and recorded by Franchet (*Bull. Soc. Bot. France*, XXXIV, p. 283), and its introduction we owe to Forrest. It is a small, rather straggling shrub, two to three feet high, with leathery, ovate leaves three to four inches long, glaucous beneath and covered with scales. The flowers are in fives, of a clear butter-yellow colour, two inches by one-and-a-half inch, with a curved style and a dense sprinkling of red-brown glands on the exterior, which enhance the beauty of the flower. As a garden plant it is almost if not quite hardy, and belongs to the Boothii phylum of the campylogynum series. *Peter the Hermit.*

COTONEASTER HUMIFUSA.

MR. GARDNER's note on Cotoneaster humifusa, on page 44, induces me to ask readers in northern gardens if they have found it fruit well with them. I had a large plant covering a rockwork mound, about twelve feet by six feet, and, although it flowered very freely, it never fruited, although most other Cotoneasters did, such as C. horizontalis, C. thymaefolia and several others in the same garden.

The non-fruiting was a source of much disappointment, yet C. humifusa is worth growing for its other merits, such as freedom of growth, freedom of flowering, its neat, low-growing habit, and the perfect cover it affords, where this is wanted, by its small, neat, deep green foliage.

All that Mr. Gardner states in its favour can be thoroughly endorsed, although his mention of its fruiting causes a feeling of regret that this little Cotoneaster has refused to fruit with me. I grew it where part of it had a good deal of sun, but part was in shade.

It is one of the easiest shrubs to propagate that I know, for its branches develop roots as they spread, and these shoots may be cut off and planted without any difficulty in establishing them. *S. Arnott.*

EVERGREEN CEANOTHUSES.

THE hardiness of these beautiful shrubs has been put to a somewhat severe test this winter, but they have come through 20° of frost without any protection. C. thyrsiflorus, the "Californian Lilac," and C. divaricatus of many lists, is one of the most robust and an excellent species for massing in open woodland, dry, hot banks and similar places. Though it will attain the stature of a small tree, it is, I think, better treated as a shrub, and a good group, planted rather thickly against a stretch of double-flowered Gorse, Cytisus praecox or C. scoparius Moonlight, can be singularly beautiful. The flowers are a pale azure, but so abundantly produced that they give the effect of a soft bluish haze which is always delightful against yellow. There is, however, much diversity in the colour of these blooms, and on their native hills this is often very apparent

C. papillosus is also a notable evergreen species, but it, too, is apt to vary considerably. Of this I have only one form, and it came under the name of C. floribundus. It is in every respect an excellent shrub, the small, narrow, bright green leaves (without the bluish metallic sheen, often seen on the foliage of the foregoing and others) being decurved at the edges and furnished with papillae. The flowers are borne in almost spherical corymbs of a clear, vivid blue; the branches are slender and whippy, and the habit dense, yet extremely elegant. This very charming species or variety is not quite so hardy as C. thyrsiflorus, but it has so far suffered very little injury here.

C. rigidus is a species of singular attraction, but it is said to be one of the most tender at Kew. Here, against a west wall, it has been perfectly satisfactory, and the deep, glossy green, close-set foliage of little leathery-toothed leaves is quite distinct. The stiff, straight branches do well against a wall and under such conditions this shrub should go up to at least a dozen feet and cover a wide area. In blossom, C. rigidus is not less distinctive than it is in other respects, the rich, violet-purple flowers being borne in the greatest profusion on the older wood in axillary umbels nearly an inch across. A well-grown specimen of C. rigidus in spring is thus a very beautiful object, and so unique that it never fails to arrest attention.

There is stilll a great deal of confusion in the nomenclature of the members of this genus, and the problem of identification is not rendered any simpler by the great variability of the plants in nature. *J. N., Wales.*

ALPINE GARDEN.

PRIMULA MARGINATA LINDA POPE.

I READ with intense interest the article on Primula marginata and its hybrids by Mr. Clarence Elliott, on page 61. He gives an excellent account of the several interesting hybrids he refers to.

Mr. Elliott places Linda Pope above the others in point of beauty, and few, if any, who know the respective hybrids he names will be disposed to cavil at his choice. It is a most beautiful plant, and the only pity is that it is so scarce and expensive. It is difficult to secure plants from nurserymen, as few traders stock it; doubtless the slowness of its propagation has a great deal to do with this.

At various times I have been asked where this Primula could be procured from the trade and have found it difficult to give a reply to this question; and frequently where Linda Pope was catalogued it was not in stock, and not forthcoming. *S. Arnott.*

ERICA VAGANS ALBA.

IN reply to Mr. S. Arnott's enquiry regarding the new white E. vagans called Lyonesse. I can assure him that while this fine variety is not free from what he considers a "defect," *i.e.*, the protruding dark-coloured anthers, the latter are much lighter in colour than they are in the old white form. But the main improvement, to my mind, in Lyonesse, is the greater size of the individual corollas (this tending to neutralise the effect of the anthers alluded to), the purity of the whiteness and the much longer and fatter racemes. Then, as in E. v. var. St. Keverne, the foliage of this new white is of a deeper green, and this also helps to accentuate the colour of the flowers. The raisers of E. v. var. Lyonesse are Messrs. Maxwell and Beale of the Dorset nurseries, and I believe it was first put on the market last year.

SAXIFRAGA GRANULATA.

THIS beautiful plant is one of the earliest to put forth a fresh spring green, its masses of little bulbils already being covered with the short-stalked, fleshy, kidney-shaped leaves. That there are various forms of S. granulata is well-known, but one rarely, if ever, sees more than one in gardens or the nurserymen's lists. I have a variety of much greater height and larger flowers than the type species usually seen, its stems sometimes rising to fifteen inches and the lovely blossoms being over one inch across. The leaves are hairy, but not so much as those of the average native species. Where this plant came from I do not know, having lost trace of its origin, but it is distinctive enough to arrest the attention of most people who see it.

S. granulata is a most adaptable species, doing well almost anywhere. But here it undoubtedly prefers a rather cool place, the foliage often withering up before midsummer where it is at all dry. As for the double-flowered variety, this doubtless lasts longer in bloom, but, to my mind, it cannot compare with the single type in elegance and refinement. *J., N. Wales.*

HARDY FLOWER BORDER.

PLATYCODON.

THE cultivated members of the genus Platycodon are remarkably effective tuberous-rooted perennials, flowering from June onwards. They are admirably adapted for either the herbaceous border or rockery. As rockery plants they are extremely effective if allowed to hang down over the rockery stones. The solitary flowers are produced on branching stems, from one-and-a-half foot to two feet tall. When established, the plants form densely branched bushes that give a profusion of blooms. The buds, before expanding, closely resemble inflated balloons and are exceedingly effective whilst in this stage; when fully expanded they are reminiscent of those of the Ostrowskia.

The plants grow best in a deep, well-drained, rich soil in a sunny situation. They should be planted from six inches to nine inches apart.

The rich, blue, prettily-netted flowers of P. grandiflorum are extremely showy, as also are those of the china white P. grandiflorum album.

P. autumnale is a late-flowering species. It has stout stems, two feet or more tall, surmounted with large, open, violet-purple flowers. It makes a grand border plant. P. Mariesii is a very rare Japanese plant of dwarf habit, not exceeding one foot in height, with large, rich blue flowers. This species is a good rockery plant. All the Platycodons are perfectly hardy, even in cold, clayey soils. They may be readily propagated from seeds or by division in spring. *W. Logan.*

LOBELIA CARDINALIS QUEEN VICTORIA.

WITH reference to the note on this plant in your issue of January 23 (p. 60), I may remark that in some northern gardens a cold frame or pit will not be found sufficient if the plants are to be in good condition in spring.

A slightly heated pit or frame is found necessary in some places, and with a little warmth the plants are much more vigorous and do much better than if wintered in a cold pit or frame. *A.*

EUPHORBIA WULFENII.

THIS handsome Spurge is always an ornament in the mixed border, woodland or foreground of the shrubbery, but it is never quite so striking as it is at this season.

Throughout the winter the narrow leaves of its ample foliage are a curious bluish green which deepens in colour as February approaches. Then the leaves nearest the apex of the flowering shoots develop a striking central line of red, the enormous flower heads almost immediately appear, and these, with their bold trusses of yellow blossom, will be conspicuous objects until spring is advancing into summer.

E. Wulfenii is a stout perennial, perfectly hardy, and it makes a dense, shapely bush up to three feet, possibly more, in height. It appears to do well in any average well-drained soil, and it is one of those plants which never seem to need any attention, yet which always look contented and healthy. *J.*

INDOOR PLANTS.

PRIMULA SINENSIS.

The indifferent manner in which the Chinese Primrose is grown in many gardens affords ample testimony that details of management in its cultivation are not always as well understood as they might be, hence a few hints and suggestions prior to the commencement of another season may be of use to growers who are not over successful with the plant.

It is yet too early to sow the seeds, but the importance of obtaining seeds of the highest quality makes it desirable not to unduly delay purchasing them

It is well-known that there is just as much trouble and expense entailed in cultivating a given number of plants, the flowers of which may not be worth looking at as there is in growing the same number that will produce flowers of the highest quality and be a source of much pleasure and joy. When it is considered that the difference in price between first- and second-rate seeds is so trifling it hardly seems possible that anyone can be so indifferent of his reputation as to buy that of an inferior strain. It should be borne in mind also that the finest strains of Primula do not produce seeds so abundantly as the inferior strains, hence it is not possible to buy seeds of a good strain at a low price.

The time of sowing must naturally be regulated to some extent by the period it is desired to have the plants at their best. To secure a stock of plants for flowering in autumn it is necessary to sow in late February or early March; for winter flowering, April is a good time to sow, while if a successional batch of plants is needed for late spring work a sowing may be made at the end of May. In all cases considerable care should be exercised in the manner of sowing the seeds, as Primulas generally are inclined to be erratic in germination. P. sinensis is no exception, and while moisture-loving to a high degree, it cannot bear anything approaching stagnancy at any stage from the seed pan to maturity.

Shallow pans are preferable to pots for sowing, but if more convenient, the latter may be used, and in either case they should be perfectly clean. To secure efficient drainage the pans should be well-crocked, using a layer of small crocks over the large ones and covering the whole with a layer of leafy material or rougher portion of the compost.

The compost that can be most highly recommended is prepared by thoroughly mixing three parts of friable, turfy loam, one part old hot-bed manure, one part flaky leaf-soil and a good sprinkling of sharp sand. The loam should be chopped into fairly fine portions and the leaf-soil and hot-bed manure may be rubbed through a coarse sieve, but it is not desirable to have a very fine compost, except for the surface layer on which to sow the seeds.

Fill the pan or pot to within half-an-inch of the rim, press the soil moderately firmly and make it perfectly level on the surface. Water thoroughly, and when the soil has drained, sow the seeds evenly on the surface and cover them with a sprinkling of sand. The seeds will germinate most readily in a temperature of about 55°, and if the pans are covered with a sheet of glass to check evaporation, and shaded, no further watering should be needed till germination is effected. Should moisture be necessary, however, standing the pans in a bath of water to the required depth is preferable to overhead watering.

In about three weeks the young plants will begin to make their appearance, when the sheet of glass should be tilted to afford ventilation, and after a few days removed entirely.

So soon as large enough to handle the young plants should be pricked off into pans of similar compost, placed in a cool position, shaded from intense sunshine but exposed to light whenever practicable. When they have filled these pans place them singly in small sixty-sized pots, give them a position as near the roof-glass as possible, and endeavour to promote a stiff, robust habit of growth by means of light and ventilation.

Immediately they have filled these pots with roots they should be transferred to five-inch pots, and for this potting a rather stronger compost may be used, adding an additional part of loam and substituting dried cow manure for hot-bed manure, if this is obtainable. Most of the plants will flower in five-inch pots, but plants from early sowings may still be potted on if extra large specimens are desired.

After May a cold frame is the best place in which to grow the plants and they will need ample supplies of water during the summer when growth is active. When established they will derive considerable benefit from occasional applications of diluted liquid manure, and for this purpose nothing is better than that obtained from cow or sheep manure. Care should be taken that the stimulant is perfectly clear, however, as if used in a turbid state a layer of manure will be formed over the surface which will not only present an unsightly appearance but prevent the water applied subsequently reaching the roots. A sharp watch should be kept for green-fly which sometimes attacks the plants, and timely fumigations should be given. The plants should not be exposed to any great degree of cold, and so soon as there is any probability of frost, remove them to the greenhouse, and as they come into flower transfer them to the conservatory, where, with proper care, they will remain in perfection a long time.

Some growers complain of their plants damping off at the base when fully grown. This may be attributed to their being potted too low, and is thus preventable. In the final potting the soil should be left slightly higher in the centre of the pot than at the sides when the water will be prevented from collecting around the base. During the winter great care should be exercised in the application of water, giving only just sufficient to keep the soil moderately moist. *A. P. C.*

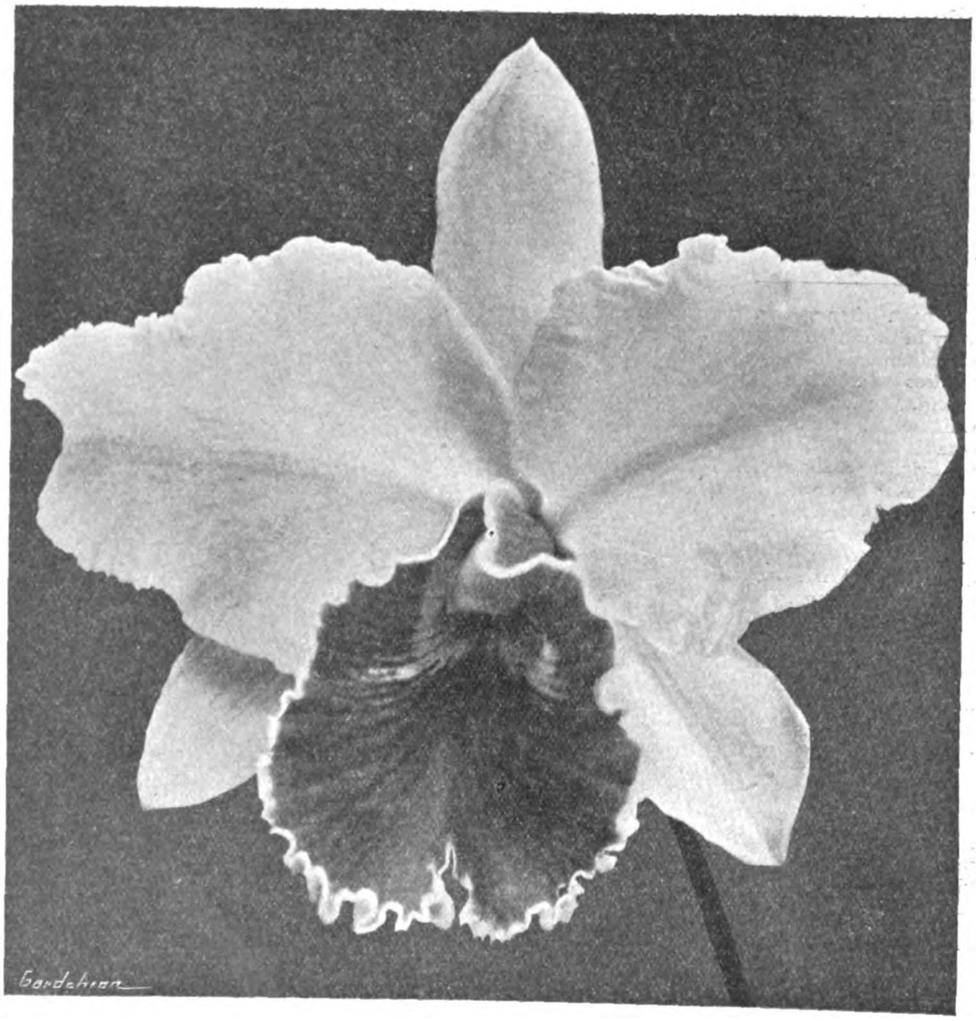

FIG. 49.—SOPHRO-LAELIO-CATTLEYA VULCAN VAR. PICOTEE.

R.H.S. Award of Merit, January 26. Flowers mauve, with rosy shading; lip purple, with mauve edge. Shown by Messrs. Black and Flory (see p. 88).

WALL GARDEN.

ANTIRRHINUM ASARINA.

Where this Antirrhinum succeeds it is a very useful plant. Though the flowers may be comparatively wanting in colour, the trailing habit and the large, Ivy-shaped, prettily scalloped leaves in a pale green, together create a singularly elegant effect. If the Snapdragon blossoms are of a somewhat watered yellow, with faint purple stripings on the "nose," one has to recognise the fact that they are large and yielded in extraordinary profusion from spring to the first frosts of autumn.

A. Asarina was introduced from Southern Italy so far back as 1699, but it has never become common in gardens, owing, probably, to it being somewhat tender and injured by excessive wet. I find that it does best between the stones of a very dry wall in full sun. In such a position a plant once established will prosper for years, making trailing shoots two to three feet long.

The whole of the plant is hairy, very sticky and brittle, and it produces seeds abundantly. This interesting plant is sometimes known as Asarina Lobelii. *A. T. J.*

GARDEN NOTES FROM SOUTH-WEST SCOTLAND.

It is somewhat interesting to note how a midwinter of unusual severity affects the date of early-flowering plants. Here it froze off and on practically from November 10 till Christmas. the temperature falling to 18°F. on three nights, and this has retarded the flowering of all except three species, namely Adonis amurensis, and the Witch Hazels—Hamamelis mollis and H. arborea—which never flinch from cold and carry their fragrant blossoms untarnished through frost and snow.

The following table shows the dates of flowering of several plants over four seasons.

	1922–3	1923–4	1924–5	1925–6
Adonis amurensis	5 Feb.	18 Jan.	...	8 Jan.
Eranthis hyemalis	23 Dec.	31 Dec.	26 Dec.	7 Jan.
Galanthus nivalis	5 Jan.	12 Jan.	20 Dec.	8 Jan.
Hamamelis japonica arborea	13 Jan.	31 Dec.	...	1 Jan.
Hamamelis mollis	26 Dec.	23 Dec.	19 Dec.	25 Dec.
Leucojum vernum Vagneri	25 Jan.	22 Jan.	5 Jan.	23 Jan.
Crocus vernus	14 Jan.	26 Jan.	20 Dec.	24 Jan.

Season after season the Witch Hazels never vary in profusion of bloom. Just as the advent of Hamamelis japonica var. arborea eclipsed the modest winter display of that old and tried friend, Cornus Mas, so did the coming of the Chinese H. mollis put us temporarily out of conceit with the Japanese species. It is certainly the brighter of the two, and the flowers are double the size of the other; but, after comparing old plants of each on this January afternoon, I incline to pronounce the colour effect of H. j. arborea to be richer than the other. At all events, it holds its own well as indispensable in these dark days.

The value of these fine shrubs is enhanced this winter by the almost total absence of Holly berries, the trees suffering reaction from the extravagant abundance of last year. Much as we unfeathered bipeds may miss the display, far more serious is the loss of provender entailed upon missel thrushes and their kin. Our old Scots proverb, "Many haws, many snaws" predicates special provision of bird food for hard winters; but whereas berries of many kinds were provided in extreme provision for the mild winter of 1924-5, the supply for the rigorous season of 1925-6 has been notably deficient.

The hybrid Escallonia langleyensis, so finely wreathed with carmine blossom at midsummer, also presents a pretty appearance in mid-winter. Inheriting an evergreen tendency from one of its parents—E. punctata—it retains its leaves into the New Year, when the foliage on the long, arching wands turns clear yellow.

Quercus Turneri, a reputed hybrid between Q. Ilex and Q. pedunculata, is another semi-evergreen, presenting a cheerful appearance at this season, and retaining its bright green foliage till it falls about the beginning of March. A tree of humble stature—I have never seen it more than thirty feet high, though it is said that it reaches fifty feet in some places—it should be planted clear of taller trees.

After the turn of the year it is well to take advantage of mild weather for setting out surplus herbaceous plants in open woodland. Many vigorous species require timely division and reduction in the border; among them, none is better worth attention than that fine American and Asiatic Wolfs-bane, Aconitum Fischeri. Its young growth is already above ground, but it will not be before September that it will crown its sturdy four-foot stems with dense spikes of lightish blue flowers.

Probably no royal manifesto ever fell more flat than the *Counterblaste to Tobacco* by King James VI and I. Doubtless, if that most economical of monarchs could have foreseen the amount of public revenue to be derived from that herb (£51,998,372 in 1925) his denunciation of smoking would have been less vehement. Many gardeners and amateurs agree with Edmund Spenser's estimate of tobacco as 'divine," but all of them may not have realised how materially the comfort of a fire-side may be increased by the provision of pipe-lighters three to five feet long. I learned this during the late war when lucifer matches were at a high premium and sometimes difficult to come by. I found that dry stems of Hemlock served well enough, but being of very light substance were soon consumed. The fallen dead branchlets of Araurcaria imbricata are more substantial and, when lighted, shoot forth a neat jet of flame from the tips; but they are awkwardly curved and will not stand properly upright beside the hearth. After trying a variety of plants, I find nothing equal to the dried stems of the Tiger Lily, which, being solid, yield a clear flame and last a long time. Considering the amount of useless and undesirable articles which are offered to philanthropic customers at bazaars, it might be worthy of the consideration of lady stall-holders whether Tiger Lily stems, done up in neat bundles and tied with gay ribbons, would not find a ready sale as pipe-lighters. One word of warning—beware of using the stems of the great Knot Weeds, Polygonum polystachyum, etc., for this purpose, because when the flame reaches a knot a sharp explosion takes place unpleasantly near the smoker's eyes. *Herbert Maxwell, Monreith, Wigtownshire.*

NOTES FROM GLASNEVIN.

Crocus laevigatus var, Fontenayi is one of the best and hardiest of the winter-flowering forms. A group in a sunny part of the rock garden is now in full flower and makes a pretty picture whether the flowers be closed or expanded. The ground colour is lilac, while the outside of the segments is heavily feathered with darker markings. Owing to the comparatively short tube and the presence of a certain number of leaves at flowering time, this variety suffers less from stormy weather than many of its kindred. In spite of the terrific gales and heavy rains the group in question shows no appreciable damage. C. vitellinus, rich yellow, but long and slender of flower, is also in bloom. The habit of this species renders it liable to damage by rough winds, and unless planted in a very sheltered position, the flowers are soon broken. With protection, however, from the overhanging branches of a dwarf shrub a proportion of the flowers escape and gladden the eyes of the visitor.

Galanthus cilicicus was the first Snowdrop of the season to bloom here. Less vigorous than G. Elwesii, it is nevertheless an attractive species producing glaucous leaves and true Snowdrop flowers on tall scapes. Mr. Bowles describes it in *My Garden in Spring* as a tall, slender form of G. nivalis, and records it as having opened several flowers with him on November 30, 1913. At Glasnevin, we expect to see the clump bursting through the soil before the Old Year is out, but so far as I can remember, we are usually into the New Year before the flowers appear.

Iris unguicularis, profiting by the warm days of last summer, is now in great beauty. The white variety was the first to open in mid-December, followed soon by the variety speciosa with lilac blooms; the distinct Imperatrice Elizabetta also calls for mention, the falls having a white ground margined and feathered blue purple. This form was acquired from Damman and Co., of Naples in 1891. Also in bloom is the variety marginata, with flowers inclined to blue rather than lilac.

Lithospermum rosmarinifolium is very freely covered with charming blue flowers showing well against the glossy dark green leaves. The plants have had no protection beyond being planted close to the wall of a greenhouse, and have experienced frosts varying from 7° to 15°, as well as violent winds and heavy rains. The reason for failure with this fine plant is, in my opinion, planting in too rich soil whereby the growth is rank and unripened on the approach of winter. I can imagine it doing well on the top of a dry wall.

Primula Winteri, planted in company with Ramondias and Haberleas, has been flowering for some time. A moist root-run but dry over-head conditions seem to meet its requirements. The position faces north and rarely gets any sun, and here, in early summer, the Ramondias and Haberleas flower profusely, while at present the grey, mealy leaves and pale lilac flowers of the Primula are conspicuous among the dark green leaves of its neighbours.

Moschosma riparium makes a fine group in the warm greenhouse, where the feathery panicles of small white flowers are reminiscent of those of a Spiraea or Astilbe. Although enjoying warm conditions during the growing season, the Moschosma does better in the greenhouse than the stove while in flower and during the subsequent resting period.

Agapetes Hosseana was introduced from Siam just over twenty years ago, and was first described by Professor Diels in *Fedde's Rep. sp. nov.*, vol. I, p. 16. The species has been in cultivation here for many years but is apparently of slow growth under cool greenhouse conditions. As growing here, it forms a dwarf shrub with somewhat stiff branches, leaves almost sessile, ovate, oblong and leathery, pale green below, darker above. The flowers, produced during summer, have red tubular corollas crowned by short lobes, and are usually solitary. The plant's chief interest at this season lies in the ornamental berry-like fruits, as large as small marbles, white, plentifully speckled with bright red dots. The genus, as a whole, is one of great interest and contains several handsome species.

Dombeya Wallichii (Fig. 50), a member of the family Sterculiaceae, is reputed to have been sent from the Mauritius to India, whence it was introduced to England by Dr. Wallich in 1820. The generic name has been changed more than once, and the plant in question has been known as Astrapaea and Pentapetes, according to the amount of importance attached to the bracts and other characters of the inflorescence by various botanists. In the *Botanical Magazine*, t. 2503, Astrapaea is used, as also in the *Botanical Register*, t. 691. There is an excellent figure in vol. I of *Sertum Botanicum*, a sumptuous work published in France nearly a hundred years ago. Dombeya Wallichii is the name now adopted in the *Index Kewensis*, and generally accepted by botanists. The specimen at Glasnevin grows in the Palm house, where it has reached a height of thirty feet, and has formed a considerable trunk which branches towards the top. The leaves are heart-shaped at the base, tapering abruptly to a sharp point: the blades are one-and-a-half feet wide, and the same in length, with petioles over a foot long. The inflorescence is in the form of a compact umbel hanging from a long, pendulous peduncle. The corolla is of a beautiful deep rose-pink colour, the styles far exceeding the staminal tube. From the figure and description of Dombeya Glaneliae (?) in *The Gardeners' Chronicle* of January 23, I should consider the plant is identical with D. Wallichii. I have no doubt our plant is identical with the figures quoted above, and I feel sure that D. Glaneliae is the same thing. D. Wallichii is by no means new to cultivation, although little known outside botanic gardens.

Jasminum Maingayi (*Bot. Mag.*, 7823) is a white-flowered Jasmine with entire leaves, and requires the temperature of the stove to develop satisfactorily. The opposite leaves are three to four inches long, dark green above, paler below. The flowers are produced in many-flowered umbels or cymes; they are pure white, but, unfortunately, scentless. The species is easy of cultivation and strikes readily from cuttings, forming a useful addition to the stove climbers at this season. *J. W. Besant, Glasnevin.*

DOMBEYAS.

In the issue of *The Gardeners' Chronicle* for January 16, I read with considerable interest the description of Dombeya Glaneliae (provisional name), to which the R.H.S. had given an Award of Merit on January 12.

According to the description, I felt almost sure that I had met with an old acquaintance, but it was not possible to feel certain, without having before me the plant itself or something definite to go upon. Now, however, on opening the copy of your paper received this morning (January 23), I have the pleasure of seeing a very accurate illustration which has fully confirmed my previous impressions. In a word, the illustration is that of Dombeya Cayeuxii, Ed. André, a description of which appeared in the *Revue Horticole*, 1897, p. 545, with a coloured plate which shows very well the colour of the flower. I raised this hybrid myself when Director of the Botanic Garden at Lisbon, by crossing Dombeya Mastersii with D. Wallichii. It is a magnificent plant, and hardy in places where the Orange tree grows. There are already some very fine specimens at Lisbon which have grown into veritable little trees, covered with large, pendant inflorescences beneath the foliage, and giving a very pleasing effect.

From the same cross I obtained, later, another variety which I named Dombeya Cayeuxii var. pallida. It differs from the first hybrid in colour, being pale pink, without the red centre which distinguishes D. Cayeuxii, type. This variety is at the moment flowering in the houses in the municipal nurseries at Le Havre.

The fact that the place of origin of D. Glaneliae is given as Madeira helps to confirm me in my certainty (Dombeyas being usually of African origin), as, on first obtaining this plant, I distributed it in quantity to horticulturists in Madeira, Funchal, etc., as well as in Algeria, Cap Vert and Egypt. I also sent some plants to your magnificent garden at Kew, where it probably still survives. See *Hand-List of Tender Dicotyledons Cultivated in the Royal Gardens, Kew*: p. 243. Dombeya Cayeuxii, Garden Hybrid (Mastersii × Wallichi).

While on the subject of the genus Dombeya, in which I am particularly interested, and of which I have cultivated numerous species, I should like to mention another hybrid, which I also obtained when in the Lisbon Botanic Garden, namely, Dombeya Davaei, H. Cayeux, which resulted from crossing D. spectabilis with D. natalensis, also described and figured in the *Revue Horticole*. This is also hardy in an Orange-growing climate, and is intermediate between the parents. It is literally covered with pink flowers in lax inflorescences produced in the axils of the leaves during springtime. I am enclosing a photograph (Fig. 48), which, unfortunately, is not very good, but which gives you some idea of the flowers. *H. Cayeux, Director of the Municipal Nurseries, Hotel de Ville, Le Havre, France.*

FLORISTS' FLOWERS.

NEW PERPETUAL-FLOWERING CARNATIONS.

The following new seedling varieties of Perpetual-flowering Carnations have been registered with the British Carnation Society. The descriptions are furnished by the Hon. Secretary, Mr. P. F. Bunyard.

Sybil.—A variety of purple-violet colour. The blooms measure three inches across and have a spicy fragrance. The plant is free-blooming and the stems are of medium substance. Registered by Messrs. Stuart Low and Co., Bush Hill Park, Enfield.

Sunrise.—A deep salmon variety with blooms three inches to three-and-a-half inches in diameter, and they are fragrant. Registered by Messrs. W. E. Wallace and Son, Eaton Bray, Dunstable.

The Favourite.—A flesh-pink variety with blooms three-and-a-half inches to four inches in diameter. Both the habit and stem are good. Registered by Messrs. W. E. Wallace and Son.

Moonbeam.—A white variety with blooms three-and-a-half to four inches in diameter. The flowers are fragrant and produced on good, stiff stems. Registered byMessrs. W. E. Wallace & Son.

Royalty.—This variety is deep mauve-coloured marked with cerise. The blooms measure three inches in diameter. The habit of the plant is good, and the flower stems are also good. It is said to be a free-grower. Registered by Messrs. W. E. Wallace and Son.

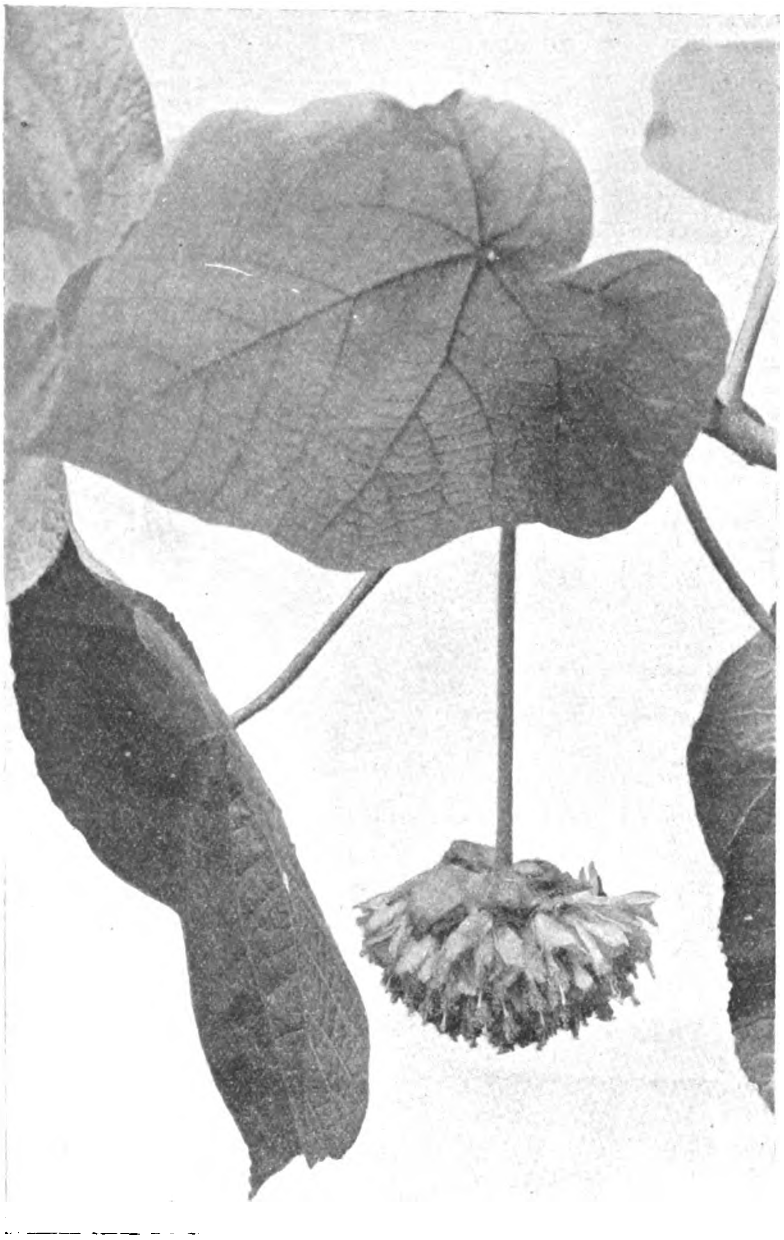

FIG. 50.—DOMBEYA WALLICHII.

(see p. 98).

Stephanie.—This variety has delicate mauve coloured petals resembling that of Peach blossom. The flowers are three inches to three-and-a-half inches in diameter. Both the habit and stem are good. Registered by Messrs. W. E. Wallace and Son.

Mrs. A. A. Viasto.—This variety has rosy-purple colouring on a white ground. The blooms measure three inches in diameter and have a fragrance similar to that of the Old Clove. The habit and stem are good; the stems are almost as strong as those of a Malmaison variety, some twenty-four inches to thirty inches long and self-supporting. The habit of growth and constitution of the plant are both excellent. Registered by Mr. J. C. Beck, The Nurseries, Henley-on-Thames.

SWEET PEAS.

Sweet Peas raised last autumn for conservatory decoration in pots should, if not already done, be placed in their flowering pots, those eight inches or nine inches in diameter being suitable.

The potting compost should consist of a good mellow loam, with sufficient sand to render the texture open and porous; a six-inch potful of bone meal may be added to every bushel of compost.

After re-potting them the plants should be carefully and neatly staked with slender canes. Cool treatment is essential at all times, and ventilation should be afforded, without causing cold draughts, on every favourable occasion. Water the roots very carefully until they are established in the fresh compost.

Where it is desired to grow Sweet Peas solely for a supply of cut flowers, the best results are obtained by planting them out in a cool house, which should be light and airy if the best results are to be expected. *C.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.

Urgent Communications.—*If sent by telegraph, these should be addressed "Gard. Chron.," Rand; or by telephone, to Gerrard,* 1543.

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

NOMOCHARIS.[*]

THOUGH doubtless as old as the hills, Nomocharis is a modern genus in a botanical and horticultural sense, for it was founded only thirty-six years ago. When Franchet[†] formed the genus he had only one species before him—N. pardanthina—which Delavay had found growing in pastures in the calcareous soil of Mount Koua-la-po, above Hokin, in the Tali country, in 1883.

In 1898, Franchet described a second species N. meleagrina,[‡] from a specimen found by R. P. Soulié on Mount Sela, on the banks of the Mekong River, but made no further additions to the genus. Franchet placed the genus "mid-way between Lilium and Fritillaria; truly related to Lilium by the nature of the bulb, dorsifixed anthers and the style; inclining to Fritillaria by the foveolate petals. From both genera it differs by the hollow inflated lower part of the staminal filaments; the much-cleft and half-free foveolae, which is seen in no other genus; the dissimilar outer and inner lobes of the perianth, which are all widely-spreading."

It is not unreasonable to assume that the genus was created as a solution of the difficulty Franchet experienced in the determination of the particular Chinese Liliaceous material before him, which he could neither relegate to Lilium nor Fritillaria. Except for the particular plant with which he was dealing, the difficulty was not altogether met by the creation of a new genus, for only one of the characters on which he relied has stood the test of time; moreover, if Franchet had lived to our day he would have been hard put to it to find more than one good and constant botanical character to separate Nomocharis from Lilium. Nor would he have found it any easier to define Fritillaria, a genus which, in his own words, "cannot be precisely defined at the present time (1898) unless one restricts it to species with a campanulate corolla of the type of that in F. meleagris, and especially to those in which the style is trifid."

Yet in the field or under cultivation Nomocharis is as distinct from both Lilium and Fritillaria as the latter are from each other. So far as is known there is no Nomocharis with flowers at all comparable to those of a Lily, the perianth in all but N. lophophora being always flat or slightly cupped; that may eventually prove an important character in the determination of the genus.

Once created, Nomocharis remained more or less in a backwater till the late Sir Isaac Bayley Balfour took in hand the enumeration of such Western Chinese material as had reached Edinburgh, especially from Forrest, and finding therein several specimens of Nomocharis, proceeded with characteristic energy to elucidate their synonymity along with that of some specimens from Kingdon Ward.

Balfour was careful to point out that his conclusions, which were embodied in a paper,[§] must not be regarded as a critical determination of Nomocharis. In his own words: "I am delving in a field I have not worked in before, and my paper is really a series of extracts from laboratory notebooks rather than a finished paper. That, however, is all that seems possible at the present time."

Under Balfour's initiative, the Edinburgh Botanic Garden became the scientific home of Nomocharis in Britain, and it is fitting that the work so ably begun on the genus by the eminent Regius Keeper should be continued under the direction of his successor.

With the arrival of ample material from Farrer, Ward and especially Forrest, Mr. Edgar Evans has recently been able to elucidate several points which for some time have been obscure in regard to Lilium and Fritillaria, and to make certain adjustments and reductions in the genus Nomocharis itself. He has also added to the genus so that it now numbers twelve species, including two new plants, N. euxantha—a deep, yellow-flowered Forrestian Ka-gwr-pu species—and N. basilissa, of which Farrer wrote so characteristically.[*] Apart from that, there has been a reshuffling of certain Fritillaria, Lilium and Nomocharis, with the result that Franchet's L. apertum (not to be confused with the variety thibeticum), and L. Henrici are transferred to Nomocharis, along with F. Gardneriana, an old Wallichian species, and F. Souliéi, a brilliant species with wine-coloured petals, which, thanks to Forrest's success in securing seeds, is in cultivation in more than one direction. Finally, that much disturbed Himalayan species, Lilium oxypetalum[†] has, as it may be hoped, reached its final resting place as Nomocharis nana, a change of genus suggested by E. H. Wilson,[‡] to whom also is due the proposal to transfer Lilium Henrici to Nomocharis. The admission of L. oxypetalun to the Nomocharis fold gives that genus a far wider distribution to the west than it has hitherto been known to have.

Three of the species originated by Bayley Balfour (in the paper already referred to) from the material then available, have been reduced, as the more ample material since received shows that the specific characters relied upon cannot be maintained; they are N. Wardii, N. leucantha and N. Forrestii. The first named now becomes a variety of N. lophophora—an old friend, Lilium lophophorum, in the new guise in which it was placed by Balfour[§]—and N. leucantha is now attached, as a variety, to N. Mairei. It has been grown in the Inverleith Garden for eleven years, and is an engaging plant.

In the main, Balfour's division of the genus into three groups—Oxypetala, Eunomocharis and Ecristata is retained in the revision: but it remains to be seen how far this grouping of what is apparantly a relatively small genus can be supported as fresh material arrives. The division sometimes turns on almost minute botanical features, such as the fan-like fringing of the glandular arras of the petals, as in Eunomocharis, or the cresting of the nectaries which is a character of the Oxypetala group, as it is of some Lilies, though incidentally it fails in Nomocharis Wardii.

A botanical discovery of interest is the fact noted by Mr. Evans that in some species the female organs of the flower of Nomocharis may frequently be entirely wanting, and the suggestion is advanced that the suppression of these parts is the result of malnutrition. The point should be easy of determination in plants under cultivation, and has, in fact, been partly cleared up by the behaviour of N. Mairei in the Edinburgh Garden over a series of years. Cultivation, too, should help to decide many of the differences noticeable in the wild plants, differences which have their origin in relative altitude, aspect, soil, rainfall, —geographical considerations, in fact—but none the less baffling in the case of herbarium specimens. In this genus, too, as in others, seminal propagation will doubtless show how far petal colour—often an elusive character—can be relied upon; and in this connection something has already been accomplished, for in his consideration of Nomocharis saluenensis (late Lilium apertum var. thibeticum, Franchet), Mr. Evans notes that certain colour forms of the species, namely typica, purpurascens and tricolor, cannot be relied upon to breed true.

How far Nomocharis will ever be a garden plant no one can say. Slowly, very slowly, it seems to be making its way in isolated positions but at present the cultivation is largely empirical. The success achieved by Mr. McDouall at Logan with N. pardanthina suggests certain cultural indications which others may follow, though they may not be blessed with the same beneficent climate and surroundings. Only continued experiment or some happy chance can show the way, as it has shown the way in the case of scores of difficult plants, and it is fortunate that seeds should have reached the hands of so many competent amateurs.

Meanwhile, as the plants figured in the Supplementary Plate show, Nomocharis lends itself readily to pot treatment, so readily, indeed, in this case, as to present a feature that must be all but unique in Liliaceous families—the presence of unopened bud, fully opened flowers and ripening capsule on the same plant.
A. Grove.

In an article on Nomocharis which appeared in *The Gardeners' Chronicle* on February 28, 1925, Mr. A. Grove—whose writings on Lilaceous plants are of such value and interest to plant lovers—made the following statements:—"The out-door cultivation of Nomocharis in this country has proved singularly difficult . . . On the other hand there seems to be no particular difficulty in cultivating Nomocharis in pots under glass without heat. The failure of the genus in the garden may be in some measure due to the difficulty of keeping the bulbs reasonably dry when they are dormant."

In view of these remarks, the photograph of Nomocharis pardanthina (var. Farreri) growing in the gardens of Mrs. Walter Jones of Aberuchill, Perthshire, may be of interest. These plants were pot-grown, in a cold frame, and had no artificial heat at any time. During the resting period the lights were placed over them to keep off the rain. As is the case with many other bulbous plants, although top growth is annual, the root-system is more or less perennial, and there seems to be no doubt that the cold rains of the average British winter, by damaging the root-system, prevent plants in the open ground from reaching their full development.

The Nomocharis make useful companions to choice Liliums and other bulbous plants which, while hardy, reach their greatest perfection in a cool house, and no lover of uncommon plants who has seen good pot-grown specimens would begrudge the small amount of care and attention demanded. The photograph (see Supplement Plate) was taken by E. Graham Stirling, Esq., Comrie.
Frederick Brooker, Aberuchill Gardens.

[*] "Upper Burma and Yunnan. Chawchi Pass, alt. 12,000-12,800 ft. This species occurs, not abundantly but occasionally, in the dwarf cane brakes of the upper alpine region, so densely impacted in the roots that I have not yet succeeded in getting bulbs; it also has one small point of occurrence only, on the crest of the Chawchi Pass, in open grass. I suspect it also is an undeveloped *Nomocharis* down on the Chinese side. The flower colour is of a pure and luminous salmon-scarlet, unspotted, like nothing so much as some wonderful strain of *Papaver orientale*. There is no 'eye' of pallor between the uniform fire-colour of the corolla and the pit of darkness at its base. The stigma and style are not green but maroon-purple, so are also the swollen parts of the filaments; their upper parts like the anthers, are bright yellow. Aberrant monoecious specimens are not of very rare occurrence, with style and ovary wanting, but with the sixth stamen sitting in the middle of the other five pretending to be of the style." In flower, July, 1920. R. Farrer 1738.

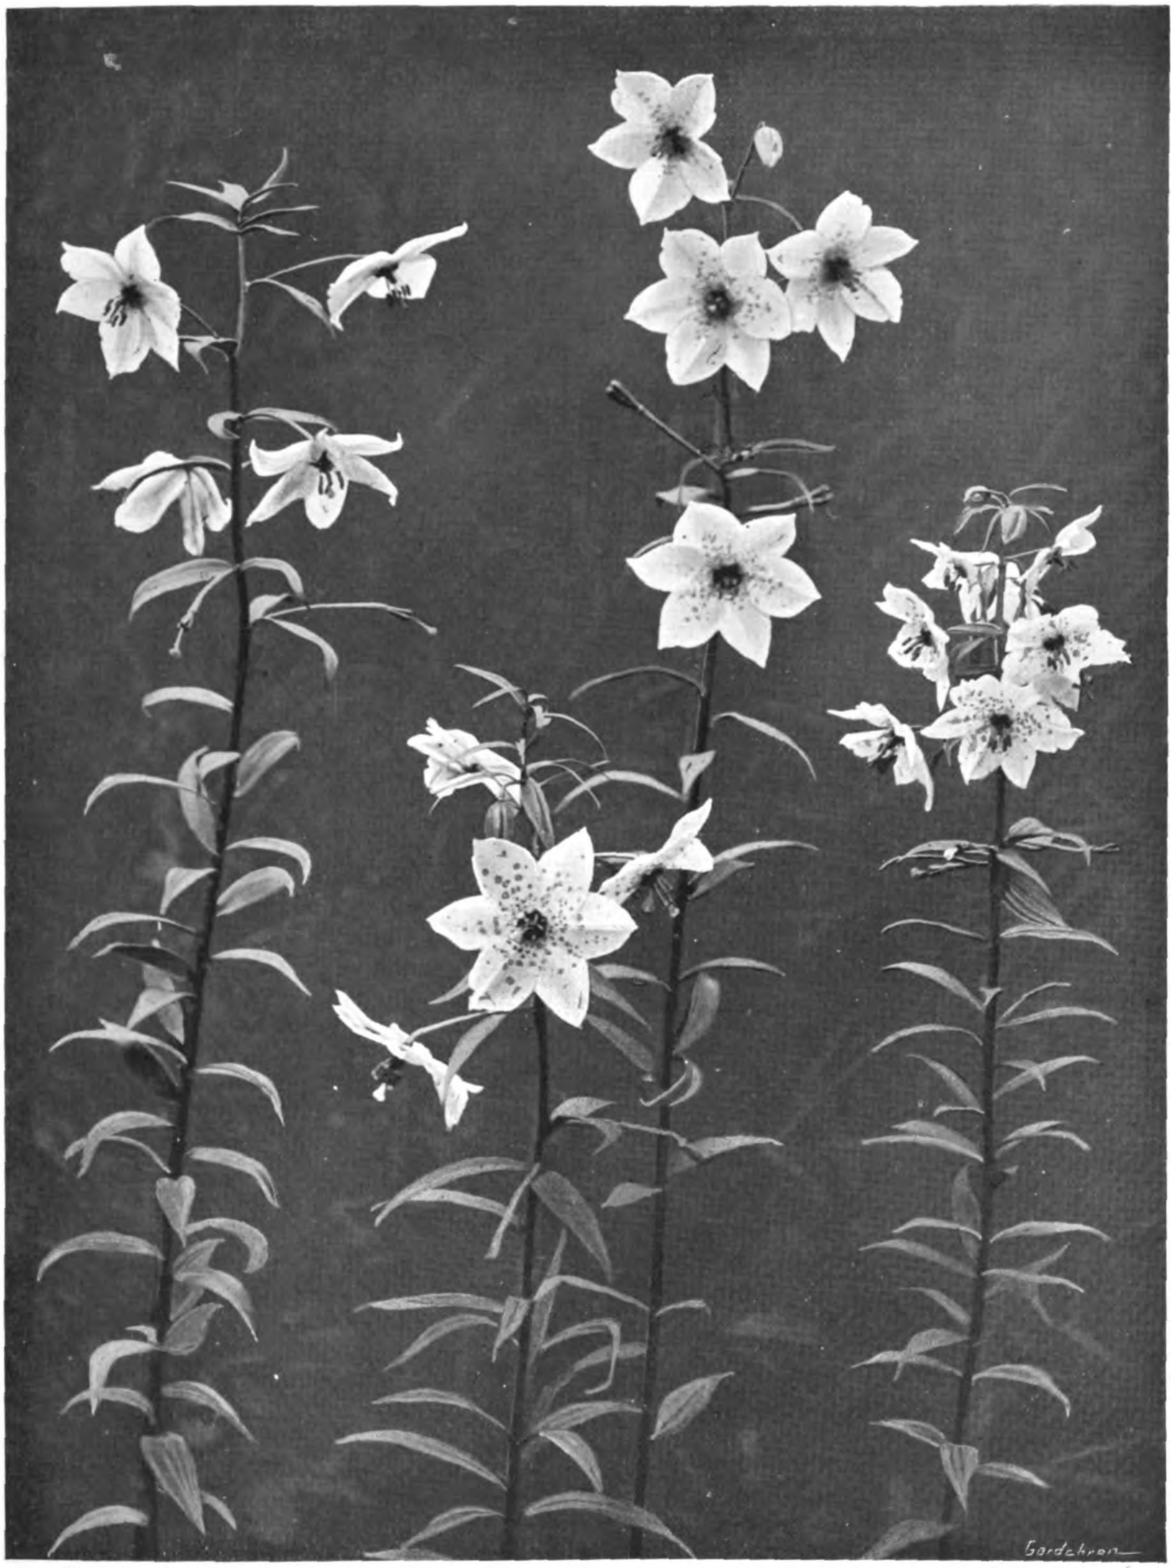
RIGHTS OF SUPPORT FOR CREEPERS.

IMPORTANT rights of support are secured by law under certain conditions to the owners of creepers. This was demonstrated in a recent case in which two judges of the High Court were required to adjudicate upon a Virginia Creeper, by way of appeal from a county court judge. The creeper had from time to time reached the gutter of a neighbouring house, the owner of which had been obliged to cut the creeper back to prevent choking of the gutter. Not content with that he went further, and sued the owner of the creeper for trespass. The county court judge held that the growth of creeper on the neighbour's wall was a trespass, but he refused to

Supplement to the GARDENERS' CHRONICLE.



NOMOCHARIS PARDANTHINA.

grant an injunction against its continuance. Instead, he ordered the owner of the creeper to pay £2 as compensation; partly for the damage it had done, and partly for the cost of cutting it back. He also made a declaration that the neighbour was entitled to enjoy his property free from interference, and that the owner of the creeper had no right to let it grow off his own premises.

The owner of the creeper appealed, as the important question as to his rights of support had been disregarded. The real question was: Could the growth of the creeper on the neighbour's house be justified by the existence of a right of support—what the law calls an easement? In the words of Mr. Justice Salter: "Was the county court judge right in holding that the defendant had no legal right of support against the plaintiff's wall for the creeper?" The two houses had originally belonged to one person, so that in those days there were no grounds for dispute. When the properties came into separate ownership, in 1918, the High Court judges held that an easement of support for the creeper was impliedly reserved. They held that this was the mutual intention of the parties. That being so, the easement justified the creeper being on the neighbour's wall. There was, however, a duty on the part of the owner to see that there was no undue interference with his neighbour's house, and therefore the award of £2 for damages was permitted to stand. The High Court held, however, that the county court judge was wrong in law in holding that the owner of the creeper had no right to the support of his neighbour's wall for the creeper. They accordingly struck out the declaration to that effect. The effect was that the owner of the creeper was entitled to let it grow on his neighbour's wall so long as it did not obstruct his neighbour's gutter.

In the event of an obstruction being caused, a neighbouring owner may cut a creeper away so far as is necessary, without notice to the owner of the creeper. If, however, the cutting can only be done by going on to the premises of the owner of the creeper, the latter's permission to enter must be asked. In that case he will probably prefer to clear the obstruction himself, to prevent any unnecessary damage to his creeper.

The right of support in the above case went back seven years. It must not be assumed that every seven years' growth gives such a right. Normally, a right of support can only be acquired under the Prescription Act, 1832, after twenty years uninterrupted enjoyment. The enjoyment of the right to an easement of support under the Act must be enjoyment "as of right." Therefore, if an easement is shown to have been enjoyed not openly, but by stealth, or if the person claiming the right has occasionally asked the permission of the neighbouring owner, no title is acquired under the Act, as the enjoyment has not been "as of right," but at the will and pleasure of the neighbour. It is only in special circumstances, as in the recent case quoted above, where one property was divided into two, that there is an implied reservation of easements. When that has happened, any period of enjoyment (however short) will enable an aggrieved person to take legal action to enforce his rights of support on his neighbour's wall, whether for Virginia Creeper, Roses, Ivy, Loganberries or any climbing plant. It is therefore possible that when a house is pulled down, the owner may be legally compelled to erect a hoarding or frame to support his neighbour's Ivy, whether the right of support has been acquired by very long usage or by implied grant on a recent partition of the premises. *R. W. Frazier.*

R.H.S. Award of Merit, January 26. Flowers pale primrose and purple. Shown by the Director, Royal Gardens, Kew. (see p. 88).

PLANS OF DRAINS.

I READ with sincere approval in *The Gardeners' Chronicle* of January 16 (p. 37), the suggestion that when new gardens are being made, etc., a plan showing the position of land drains would prove useful, and I hope the Earl of Chichester's proposal at the meeting of the Council of Agriculture will be acted on, viz., that legislation be introduced to make it compulsory in future for plans of drains on agricultural land to be attached to the deeds of the land, and also to any agreement for the letting of such land.

Some such legislation is surely needed, too, in connection with domestic drains. I am reminded of an experience I had a few years ago. I had been living in a cottage for a year or so, and in view of a lot of throat illness in my family during that time, my doctor advised me to have the drains tested. I wrote to the surveyor to the local powers asking him to test the drains. He replied that if I would expose the inspection chamber he would readily do so.

Exhaustive researches failed to reveal any trace or knowledge of an inspection chamber, and I could only find circumstantial evidence of the existence of drains at all. There were manholes in the road outside, suggesting a main sewer, and there were the customary above-ground gadgets about my premises to suggest drains beneath, but there was absolutely no evidence to show any connection between these and the sewer. Things passed down them, but what happened to them after was a matter of pure supposition. There was neither plan nor local lore nor legend to say whether we drained into the sewer, the gas main or the water main !

At the back of the cottage was a small asphalt yard, and in our part of the asphalt was a slight depression. A local labourer, wise in such matters, "felt it in his bones" that the inspection chamber was at this spot, so I engaged him to excavate and see. On returning a little later, I found an ugly gash in the asphalt, and my man standing by with a very scared face. He had put his pick through the asphalt and then stamped his foot, and had gone through up to the knee, and then, after an awful interval, he had heard a splash. It was a disused well, seventy feet deep and with fifteen feet of water at the bottom. Originally, it had been drained and boarded over, then gravelled over—and, later, forgotten—and lastly, someone had tarred the gravel. The beams and boards had entirely rotted away, and the only covering to that seventy-foot death trap was a slightly concaved skin of tarred gravel. It lay in the main thoroughfare from the road to the kitchen door. Every tradesman who came to the house walked over it ! I saw to it that this well was roofed over with enormously strong, re-inforced concrete, but I regret to say that I did not see to it that its existence and position were recorded in any local archive. There seemed to be nowhere to record it. Nor, bye-the-bye, did I ever discover the inspection chamber, nor the alleged drains. I left the cottage shortly after this adventure with the well.

I remember a rather similar thing happening, years ago, at a Chelsea flower show. Someone was excavating for a rock garden, when the wheel of a passing cart crashed through up to the axle into a disused and forgotten well. Memory of such incidents make me agree most heartily with the suggestion that the recording of drains, *all* drains, and wells, cesspools and underground tanks, too, should be compulsory. *Clarence Elliott, Stevenage.*

MESEMBRYANTHEMUM.

LITHOPS.

(*Continued from page* 80).

L. Francisci, N. E. Br.—Growths 9–18 lines high, 6–14 lines broad, and 4–9 lines thick, obconic, flat and elliptic in outline at the top, with a transverse fissure 3–7 lines deep ; surface smooth, glabrous, pale-greyish-white or dirty ivory-white, covered with dendritic green or grey-green markings and numerous darker or blackish dots, and sometimes flushed with reddish-yellow. Flowers not seen, described as being small, 5–8 lines in diameter ; petals about 30, linear-lanceolate, yellow. Anthers numerous, yellow. Capsule 5-celled.

Mesembryanthemum Francisci, Dinter in *Fedde Repert., Beihefte*, vol. XXIII, p. 62 (1923), and in *Zeitschr. f. Sukk.*, vol. I, p. 92 (December 1923), and vol. II, p. 19, with fig. (January, 1925).

Great Namaqualand : At Hahlenberg, Dinter 3743 ! and Kovis Mountains, Eberlanz and Stoeber.

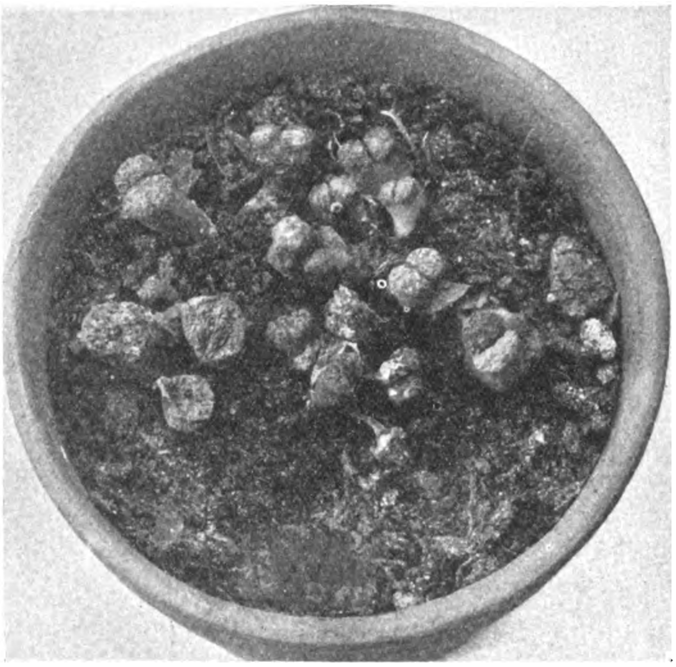

FIG. 52.—LITHOPS MARLOTHII, N. E. Br.
(Three-quarters natural size).

L. Friedrichiae, N. E. Br., in *The Gardeners' Chronicle*, 1922, vol. LXXI, p. 55. To this add the references :—Karsten in *Onze Tuinen*, July, 1924, pp. 42-43, with fig. Mesembryanthemum Friedrichiae, Schwantes in *Monatssch f. Kakt.*, September, 1920, p. 132.

Lithops Julii, N. E. Br.—Growth 9–14 lines high and 7–10 lines broad, obconic, elliptic in outline, with a transverse fissure 2–3 lines deep across the flat, wrinkled top, of a pale opaque greyish-opaline colour, marked with slightly depressed branching wrinkles that are somewhat semipellucid, and at the margins of the fissure with ochraceous-brown lines or dots. Corolla 12–14 lines in diameter ; petals numerous, 1 line broad, lanceolate (they are probably cuneately linear), obtuse, white.

Mesembryanthemum Julii, Dinter in *Zeitschr. f. Sukk.*, vol. I, p. 145 (June, 1924), and Dinter and Schwantes in *Zeitschr. f. Sukk.*, vol. II, p. 26, with fig. (March, 1925).

Great Namaqualand : Between Vahldoorn and Warmbad, and also near Warmbad, Dinter.

L. karasmontana, N. E. Br.—This name must take precedence of that of L. damarana as being the earlier, the synonymy being :—Mesemb. karasmontanum, Dinter and Schwantes in *Monatssch. f. Kakt.*, March, 1920, p. 36, with fig. M. damaranum, N. E. Br., in *Journ. Linn. Soc.*, vol. XLIV, p. 67 (July, 1920). Lithops damarana N. E. Br. in *The Gardeners' Chronicle*, 1922, vol. LXXI, p. 80 ; Karsten in *Onze Tuinen*, August, 1924, page 78, with fig.

This species occasionally produces 2 or 3 flowers from the same growth, which I have never observed to be the case with any other species of this genus.

L. Lericheana, Dinter and Schwantes in *Zeitschr. f. Sukk.*, vol. II, p. 25. Growths $\frac{2}{3}$-$1\frac{1}{2}$ inch high and 7–14 lines broad, obconic, more or less circular in outline at the top, with a transverse fissure $1\frac{1}{2}$-$2\frac{1}{2}$ lines deep, and the top of the lobes flat or very slightly convex, of a reddish-bluish-ochreous colour, with broad branched pellucid wrinkles. Petals white. Capsule 5-celled.

Mesembryanthemum Lericheanum, Dinter and Schwantes in *Zeitschr. f. Sukk.*, vol. II, p. 25 (March, 1925).

Great Namaqualand : Near Garub, Great Karas Mountains, Dinter.

L. Lesliei, N. E. Br., in *The Gardeners' Chronicle*, 1922, vol. LXXI, p. 65. To this add the following references :—Mesembryanthemum Lesliei, Schwantes in *Monatssch, f. Kakt.*, September, 1920, p. 129, and M. ferrugineum, Schwantes in *Monatssch. f. Kakt.*, June, 1922, p. 93.

The plant which Mr. Schwantes has named M. ferrugineum is merely a variety of the plant with the markings on the top, dense, and of a rust colour. For this plant, as do some other species of this genus, varies very much in colour, and in its markings ! I have about five variations in cultivation, one form being almost without markings on the top. The form named M. ferrugineum by Schwantes was found by Dr. R. Marloth in Griqualand West. I have the plant, and the same form also from the Transvaal and Bechuanaland ; it is densely covered with rust-coloured markings. Even in the same vicinity the colour and the density of the markings vary greatly, and under cultivation they vary somewhat from year to year. Their flowers also vary in size. This year two of my plants that are similar in colour and markings, differed greatly in the size of their flowers ; one had a flower 20-22 lines in diameter, with petals 8–9 lines long and stamens 5 lines long ; the other had a flower 30 lines in diameter, with petals 13 lines long and stamens 6 lines long.

L. Marlothii, N. E. Br. (Fig. 52).—Growths when first developed after importation 6 lines high ; 4–5 lines broad and 3–4 lines thick, probably becoming larger under cultivation, with a transverse fissure 1 line deep across the truncate top ; lobes equal or unequal sub-contiguous, flattish or very slightly convex on the top, rugose, from its surface being covered with small, glittering, bright, translucent green pimples intermingled with raised, irregular, branching lines, mostly directed inwards from the margin, and of a light creamy-ochreous opaque colour ; with age, the green pimples appear to become dull and brownish. Flowers not seen, probably small. Capsule when closed about $1\frac{1}{2}$ line in diameter, with a short conical point on the top, very pale brownish, 5- or occasionally 4-celled ; valves spreading, very acute, with the expanding-keels closely contiguous throughout into an acute pallid central keel, and with broad rounded membranous marginal wings that are more or less united in pairs between the valves. Seeds minute, about $\frac{1}{4}$ line long, ovoid, smooth, whitish.

Little Namaqualand : Near Ookiep, Marloth 6903 !

This very distinct species is small, but very charming, a real gem, especially when seen under a lens, quite unlike any other known to me, and I have very great pleasure in naming it after its discoverer, Dr. R. Marloth, who kindly sent it to me. *N. E. Brown.*

(*To be continued.*)

PLANTS IN FLOWER AT LA MORTOLA.

CECIL HANBURY, Esq., has forwarded us the following list of plants which were in flower in his famous garden at La Mortola, Ventimiglia, Italy, on January 1. The list enumerates four hundred plants, and those asterisked are species or varieties that were giving a good display of colour at the time.

Abelia chinensis, Abutilon Darwinii, A hybridum and A. striatum ; *Acacia Baileyana, A. brachybotrya, A. cultriformis, A. dealbata, A. glaucophylla, A. glaucoptera, *A. Hanburyana, A. lineata, A. Maidenii, A. microbotrya, A. neriifolia, *A. podalyriaefolia, A. pubescens, *A. retinodes, A. Sentis, A. Siebertiana, A. uncinella ; Agathaea coelestis and *A. hispida ; *Ageratum mexicanum, Albizzia lophantha ; Aloe abyssinica, A. affinis, A. arborescens var. Milleri, *A. arborescens var. natalensis, A. arborescens, var. Ueriae, A. caesia, *A. ciliaris, A. comosa, A. glauca, A. ferox, A. Johnstonii, A. laetecoccinea, A. laxiflora, A. longiflora, A. percrassa, A. Pienardii, A. pluridens, A. pretoriensis, A. Quihlii, A. rubrolutea, A. rubroviolacea, A. Salm-Dyckiana, A. smaragdina *A. speciosa, A. speciosa hybrida, A. spinosissima, A. succotrina, A. supralaevis, A. Wickensis and A. Winteri ; Alyssum maritimum, Anagyris foetida, Andropogon hirtus, Anemone coronaria, Antirrhinum majus, Aponogetum distachyum, Arbutus Unedo, Arum Arisarum, Asparagus aphyllus, Asphodelus acaulis, Azalea indica.

Banksia marcescens, Begonia miniata, B. macrophylla, B. Rex, and B. semperflorens ; Bellis sylvestris, Berberis glauca, Bergenia cordifolia, Bignonia australis and *B. venusta, Billbergia speciosa, Borago officinalis, Bougainvillea glabra, *B. glabra Sanderiana, B. spectabilis and *B. lateritia ; Bouvardia leinantha, *Buddleia asiatica, B. auriculata, *B. madagascariensis, and B. officinalis ; Brassica insularis.

Caesalpinia tinctoria, Calendula arvensis, *C. officinalis fl. pl., and C. stellata ; Camellia japonica, Campanula Trachelium, *Canarina Campanula, Cassia artemisioides and *C. tomentosa, Casuarina Cunninghamiana, C. equisetifolia, C. glauca, C. stricta, and C. torulosa, Caltha edulis, Ceanothus azureus, Centaurea aspera and C. Cyanus, Cepholataxus drupacea, Cestrum aurantiacum, C. Parquii and C. suberosum ; Cheiranthus Cheiri, *Chimonanthus fragrans, Chlorophtum elatum, Chrysanthemum anethifolium, C. frutescens, and C. hybridum ; Cineraria stellata, Cistus incanus, Citrus Aurantium and C. Medica, Centranthus ruber, Clematis cirrhosa, Clivia miniata, Colletia cruciata and C. spinosa, Correa Lawrenceana, Colquhounia vestita, Convolvulus floridus, Coriaria sinica, *Coronilla glauca, Cotoneaster divaricata, Cotyledon macrantha, Crassula lactea and C. portulacea, Crotolaria capensis, Cyclamen persicum, Cyperus alternifolius.

Dasylirion glaucophyllum and D. serratifolium, Dimorphotheca Ecklonis, *Diplopappus filifolius, Dodonea Thunbergiana, Dombeya Cayeuxii, Duvernoya adhatodoides.

Echeveria gibbiflora, ***E. multicaulis, and E. pachyphytioides ; Echium formosum and E. plantagineum, Eleagnus pungens var. reflexa, Ephedra altissima, Eriobotrya japonica, *Eriocephalus africanus, Escallonia floribunda, Eucalyptus coriacea, E. crebra, E. ficifolia, E. diversicolor, E. Globulus, E. melliodora, and E. sideroxylon*, Eupatorium calaminthifolium, *E. grandiflorum, E. micranthum and E. album ; Euphorbia dendroides, E. grandicornis and E. triangularis ; Euryops spathaceus, Farfugium grande, Felicia abyssinica, Forsythia intermedia, Fraxinus xanthoxyloides, Freylinia oppositifolia, Fuchsia arborescens, F. corymbiflora, F. hybrida, *F. triphylla, and F. splendens ; Fumaria officinalis.

Gaillardia picta, Garuleum viscosum, Gasteria Lauchei, *Gazania splendens, Genista ferox, and *G. monosperma, *Gerbera hybrida and G. Jamesonii, Globularia Alypum, Grevillea Preissei and G. Thelemanniana, Gynerium argenteum.

Hakea cristata, H. laurina and H. suaveolens ; Halleria lucida, Hedera canariensis and H. Helix ; Hardenbergia Comptoniana, H. monophylla rosea and H. monophylla violacea ; *Heliotropium peruvianum, Helleborus hybridus and H. foetidus, *Hexacentris coccinea, Hibiscus Rosa-sinensis, Hyacinthus romanus.

*Iberis semperflorens and I. sempervirens ; *Iochroma coccinea, I. grandiflora, I. lanceolata and I. tubulosa ; Iris germanica, *I. unguicularis, I. unguicularis var. alba.

Jacobinia magnifica, J. pauciflora, and J. penrhosiensis ; Jasminum nudiflorum and *J. primulinum, Juniperus Oxycedrus.

Kalanchoë Dyeri, K. marmorata and K. Schimperiana ; Kleinia ficoides, K. mandraliscae, K. neriifolia, K. nyikensis, K. odora, and K. repens.

Lantana Camara, *Lathyrus odoratus and L. sativus, Laurus nobilis, Lavandula abrotanoides and *L. dentata, Leonotis Leonurus, Leptodermis lanceolatus, Leptosyne gigantea, Linum grandiflorum, Lobelia speciosa, Loeselia coccinea, *Lonicera Standishii, Lopezia miniata.

Mahonia Bealei, Malvaviscus mollis, Mamillaria elegans and M. rhodantha, Matthiola hybrida, Mesembryanthemum aequilaterale, M. blandum, M. blandum atropurpureum, M. confertum, M. corniculatum, M. curviflorum, M. diversifolium, M. echinatum, M. Ecklonis, M. elegans, M. ficifolium, M. laeve, M. lepidum, M. linguiforme, M. megarhizum, M. productum, M. rubricaule, M. stelligerum, M. subincanum and M. tigrinum ; *Montanoa bipinnatifida and M. tomentosa ; Monstera deliciosa, Moricandia arvensis, Muehlenbeckia complexa and M. platyclada ; Myoporum acuminatum.

*Narcissus canariensis, N. Tazetta aureus, N. Tazetta pachybolbus, and N. Tazetta polyanthus ; Nardosmia fragrans, Nemesia strumosa, Nerine Bowdenii, Nicotiana glauca.

Odontospermum sericeum, Olearia Forsteri, Oreopanax dactylifolius, O. capitatus and O. palmatus ; Othonopsis cheirifolia, Orobanche ramosa, Osmanthus Aquifolium and O. fragrans, Othonna crassifolia and O. triplinervis, Oxalis cernua and *O. purpurea.

Paspalum dilatatum, Passiflora capsularis, *Pelargonium lateripes, P. peltatum and P. zonale ; Peumus Boldus, Photinia serrulata, Phylica rosmarinifolia, Pilocarpus pennatifolius, Pithecoctenium buccinatorium, *Plumbago capensis, Poinsettia pulcherrima, Polygala cordata, P. myrtifolia and P. apopetala ; Primula kewensis, *P. malacoides, *P. obconica, and *P. sinensis ; Psiadia glutinosa.

Rhaphiolepis indica, *Reinwardtia trigyna, Reseda Phyteuma and *R. odorata, Rhamnus Alaternus, Rhipsalis Cassytha and R. zanzibariensis, Rosa Banksiae, *R. bourbonia, *R. indica, R. indica major, R. sinica anemonaeflora, R. viridiflora and *R. Thea var. Safrano, *Rosmarinus officinalis and *R. humilis, Ruta graveolens, Ruscus Hypoglossum and R. Hypophyllum, Russelia juncea.

Salvia cacaliaefolia, S. chamaedryoides, S. discolor, S. Grahamii, S. gesneraefolia, S. elegans, S. amarissima, *S. Heeri, *S. involucrata, S. leucantha, *S. mentiens, S. mexicana, S. pulchella, S. paniculata, *S. semiatrata, and *S. Sessei ; Schinus dependens and S. Molle, Sarcococca pruniformis, Satureia viminea, Sempervivum arboreum and S. holochrysum, Senecio angulatus, S. deltoides, *S. grandiflorus, S. longiflorus, S. hadiensis, S. mikanioides, and S. Petasitis ; Sida mollis, Solanum auriculatum, S. Hartwegii, S. jasminoides, S. nigrum, and S. sisymbrifolium ; Sphaeralcea umbellata, *Statice brassicaefolia, S. macrophylla, S. macroptera, and S. Perezii ; Stenolobium stans, Streptosolen Jamesonii.

Tagetes lacera, Tecomaria capensis, *Templetonia retusa, Tetrapanax papyriferum, Teucrium fruticans and T. heterophyllum, Tournefortia Messerschmidia, Tropaeolum majus.

Ulex europaeus.

Verbena officinalis, Veronica Andersonii and V. salicifolia, Viburnum Tinus, *Vinca major and V. media, Viola odorata, Visnea Mocanera, Vittadina triloba.

Westringia rosmariniformis.

*Yucca elephantipes and Y. flexilis.

FORESTRY.

THE INFLUENCE OF PROLONGED DAYLIGHT IN THE VEGETATIVE SEASON ON THE QUALITY OF CONIFEROUS TIMBER GROWN AT HIGH LATITUDES.

(*Continued from p. 84*).

IN Finland, all of which lies to the north of the 60th parallel of latitude, and which produces "in the finest quality the timber trees most commonly used for architectural and building purposes," it is in the north that, according to M. Frederiksen, "we often meet with the long, healthy Pines, as straight as the most perfect columns, and such as are rarely seen in Central Europe."* From about the middle of Finland (approximately 64°) to the southern limits of the country we have a forest area which corresponds in latitude with that of the great forest region of Northern Russia. In the south, according to M. Frederiksen, in a moderately rich soil, the Scots Pine takes 82 years to attain a diameter of 7¾ inches (approximately 24 inches in girth) at 23 feet high; in Central Finland it takes 105 years, and in the north 130 years to reach the same diameter at this height. These girths give respectively 21, 27, and 33 wood rings to the inch. In the Lake Enare district (70° N.), where the longest "day" corresponds to two months, a Pine takes over 300 years to attain a diameter of 10 inches at 20 feet high, giving about 60 wood rings to the inch, but at this latitude useful tree growth has, of course, passed its northern limit, and there, just as at extreme elevations at lower latitudes, it is extremely slow.

In the northern hemisphere the timber of the Scots Pine, when grown under natural conditions, that is, as self-sown, untended forest, exhibits, as we have seen from statistics already published, a progressive diminution in the width of the annual wood rings as its habitat recedes farther and farther from the southern limit of the distribution of the species, and this is correlated with a progressive diminution in the chemical intensity of the sun's rays, direct and indirect, and of weaker and weaker illumination, owing to their increasing obliquity and the greater and greater depth of atmosphere which they have to penetrate, as we go northwards. Were the earth's axis perpendicular to the plane of the ecliptic, the production of this or, in fact, of any other kind of timber at these high latitudes would be impossible, for there would be no seasons, the daily duration of sunlight would be equal over the whole globe, and its intensity in these latitudes would be insufficient to produce it. All over the globe the sun would ascend daily to a position above the horizon corresponding to the co-latitude of the point of observation, and everywhere the climatic conditions which now obtain at the equinoxes would be constant throughout the year. The northern limits of the Scots Pine and Spruce, and of all other seed-bearing plants, would recede many degrees southwards, and in the temperate zone the geographical distribution of all flowering plants would be greatly restricted, for at their present northern limits they would be unable, owing to insufficient solar light and heat, to ripen their seeds and reproduce themselves. But owing to the inclination towards the sun of the north pole of the earth, the intensity of the solar heat is so greatly increased, and the duration of the daylight so enormously lengthened in the summer half of the year, that they are able to extend their distribution many degrees farther northwards than would be the case were the earth's axis not so inclined.

---

* Notes on Forestry in Finland, by John F. Annand, *Transactions* of the Royal Scottish Arboricultural Society, Vol. XVII, p. 243 (1904), compiled chiefly from *Finland*, by N. C. Frederiksen, formerly Professor of Political Economy in the University of Copenhagen.

As may be seen from the table, published on p. 49, at about the middle of the forest region of Northern Russia and the part of Finland lying between the same parallels of latitude—that is, at approximately 64° N.—at the spring equinox the chemical intensity of the sun's rays is considerably less than one-half of what it is at that time 23½° farther south—that is, at the centre of the Spanish Peninsula. Owing, however to the inclination of the earth's axis from the perpendicular to the ecliptic by this amount, at the summer solstice these forest regions are brought daily into a position in the sun's rays which corresponds to that of the centre of Spain at the equinox, so that at this time both the chemical intensity of the solar rays and the duration of the daylight at 64° N. are practically double what they were at the equinox; in fact, at this time (which is the winter solstice in the southern hemisphere) the equatorial regions receive but one-third more solar heat than these forest regions receive, but approximately one-half of the daylight. Put in another way, by the movement of the earth in its orbit from the vernal equinox to the summer solstice, in the northern hemisphere every point on its surface is carried southwards in space, and therefore in the sun's rays, daily by no less than 1,600 miles, and at the middle of the growing season therefore these forest regions enjoy sunlight of the same chemical intensity as that enjoyed by Spain at the vernal equinox, with practically double the duration of daylight received there at that time, while at the North Pole for some weeks at this time as much, or perhaps more, solar heat is received than at the terrestrial equator.[*] *A. D. Richardson.*

(*To be continued.*)

NURSERY NOTES.

MESSRS. SUTTON AND SONS, READING.

In winter, when flowers are more appreciated than at any other season, some of the brightest members of the floral community may be brought to perfection under glass, and our exhibitions and flower markets at this season prove the great variety obtainable when frost and storms are prevailing in the open.

Some exotics which can be forced into flower in winter require much skill on the part of the cultivator to bring them to perfection, but there are others that are available to all who care to take the little trouble their cultivation entails. For instance, few plants can be flowered with greater ease than the florists' Primula and the Cyclamen. These two flowers are popular with all gardeners,and their popularity is evidence of their worth. If proof were needed of the important place they occupy in indoor gardening, a visit should be made at this season to the nursery of Messrs. Sutton and Sons, at Reading, where the majority of the glasshouses in this large establishment are ablaze with the bright colours of the two plants we have just named. House after house is filled with Primulas and Cyclamens of the choicest varieties and finest strains in cultivation, and the inquisitive may note some plants placed apart or specially marked, in which some variation in the flowers, habit or colour is evident.

Both members of the same great family—the Primulaceae—they have but little resemblance to one another, and it would be hard to say which is the more beautiful or decorative, or which has been the more improved by raisers. Take the Cyclamen, for example; the change brought about in this flower is little short of marvellous. It was introduced to Europe nearly two hundred years ago—one hundred-and-ninety-five to be exact—yet this is not a long period judged by the ages during which the plant has existed in a wild state. The flowers of the introduced plant were white, with a darker ring around the throat, and they were fragrant. The old crimson and white form was described by Miller in 1768 as fragrant, an attribute which most of the modern varieties lack, but Messrs. Sutton and Sons have still in cultivation a fragrant form of this type which is known as "Persicum White"; they also list a large-flowered, sweet-scented strain of mixed colours.

With regard to the original Cyclamen, there appear to have been two forms. The one with pink flowers was the first to be introduced to Europe, in 1731, and was obtained from Syria; the other, a white-flowered form, found in Palestine, is very fragrant.[*] The ring of colour around the base of the corolla gave the opportunity for obtaining colour variation, and perhaps the most striking variety showing the intensification of colouring in the petals is Vulcan, the petals of which are wholly of a deep crimson shade.

The range of colours is now very great, and we have varieties of salmon, salmon-scarlet, salmon-pink, crimson, mauve, sealing-wax red and intermediate shades between these tones. Of all the numerous varieties in the collection none appeal to us more than the salmon types, such as Salmon Pink and Salmon Scarlet. Firefly is a variety of unique colouring, and may best be described as sealing-wax red. Whilst the colour has been intensified in these sorts, it has been entirely eliminated in others, such as in Giant White. In addition to the improvement in the colours, the flowers themselves have been greatly enlarged in size, and whilst probably the smaller-flowered types are of the most perfect form, the old C. latifolium itself being of beautiful symmetry with twisted petals, these giant forms are very imposing; a flower and bud of Giant Shell Pink is reproduced in Fig. 53.

Amongst other changes which the Cyclamen has undergone during the comparatively short period during which it has been in cultivation, is the cresting of the florets, giving rise to the crested varieties, and the fimbrication of the margins of the petals, as seen in the Butterfly types. A plate of these Butterfly Cyclamens, or, as they are sometimes known, Cyclamen Papilio, was published by Mr. Ernst Benary in 1899. Fringing has also developed in some cases on the leaves, and a remarkable example of this leaf fringing was illustrated in *Gard. Chron.*, April 7, 1900, Fig. 70. The flowers of Cyclamen sometimes open like an umbrella, and an example of this abnormal development may be seen in Messrs. Sutton and Sons' collection at the present time.

Apart from the beauty of the flowers, Cyclamens have most ornamental foliage, and these plants are good decorative subjects for the greenhouse and conservatory, even when not in bloom. That such wonderful development has been attained in the Cyclamen is the more remarkable in that it has never been crossed with any other species.

With regard to the Reading Primulas, similarly interesting facts might be told, but these must be deferred for another occasion, beyond stating that improvement is evident in all types of the flower.

HOME CORRESPONDENCE.

Does Frost Kill Insects?—In reply to Mr. G. C. Johnson (p. 68), I do not think that severe weather has any appreciable influence in reducing the insect pests of fruit trees. I can still find woolly aphis alive on my trees, also Apple blossom weevils; and the other day, whilst pruning, I found a caterpillar of the lappet moth extended on a shoot in a most exposed position, and alive. Most of the insects are, of course, in the egg stage, in which they are certainly immune from harm. Even when they are exposed to frost after hatching they do not succumb, unless they are starved. I have found aphides and young caterpillars alive in the blossom clusters of Plums after a blizzard which coated the trees with snow. More reliable evidence than mine was given by Mr. J. G. Blakey in *The Gardeners' Chronicle* of February 14, 1920, as this observer made most painstaking investigations in several seasons. He found that several species of aphides, including the Rose aphis and the leaf-curling aphis of the Apple (Anuraphis roseus), survived frost and snow, even up to 21° of frost. *Market Grower.*

Subsidies for Houses constructed of British or Imperial Timber.—The prospect that in the near future the State will come to the aid of the rural landlord—who at present is unable either to charge an economic rent or to carry out necessary structural alterations—leads me to ask you to give publicity to suggestions recently made by the Essex branch of the Incorporated Society of Auctioneers and Landed Property Agents. Put simply, these are to encourage the Government to grant further subsidies on houses constructed of British or Imperial timber. Doubtless, the same derisive critics who have dubbed the Weir house a "sardine tin," will now sing of "little wooden huts," but the fact remains that a very large number of dwellers in country areas will discuss the suggestion with interest. According to the Ministry of Health's letter to us, dated January 16, "The Minister is prepared to consider sympathetically any proposals from local authorities which seem likely to promote economy or speed of erection in the provision of houses, and in certain instances he has given approval to proposals for the erection of houses constructed mainly of wood." In this connection attention is specially drawn to Section 23 of the Ministry of Health Circular No. 520. In support of the suggestion for more such houses, I would state that there remain in sound, habitable condition a number which were built during a shortage at the time of the Crimean war, seventy years ago. Constructed of seasoned timber, lined internally with asbestos, and built upon concrete foundations, it is believed that a house, comparable in size with the brick or stone dwellings now being erected for the housing of the working classes, would cost approximately £230. Based on this sum, an average subsidy would be about £75. It may further be remarked that in the event of such a suggestion being found practicable on a large scale, the timber industry would be greatly benefited and unemployment in this branch of our trade practically disappear. And first and last, a contribution of considerable magnitude would have been made towards the solving of the centuries' old rural housing problem. May I say, in conclusion, that this society has no direct interest whatever in the matter, but is actuated solely by desire for the welfare of the nation as a whole. *John Stevenson, Secretary, 26a, Finsbury Square, E.C.2.*

Romneya Coulteri.—I can assure Mr. Harrison that, under certain conditions, Romneya Coulteri produces suckers, and young plants spread freely therefrom. The colony I refer to, for such it was, I had under observation for many years. It spread somewhat annoyingly about a very sunny, sloping bank, where the parents overshadowed quantities of Tulipa Clusiana, and other than an occasional digging or mulching received scant attention. The sub-soil was calcareous shale, about fifteen inches below the surface. I mention this fact because it proves or is the sequel of two young root suckers spreading and producing numerous young plants all over a radius of six to eight feet; these could be traced to the roots issuing from the parent plant, which, in such a position, came quickly to the surface. The shoots flowered freely in the case of the strongest growths, and were cut away afterwards. Under such conditions, few, if any, seeds were produced. I must state, however, that the conditions on the Riviera are altogether different to those at home; the plants grow away after the heavy rains, and then come many weeks of brilliantly hot weather such as we seldom experience in England. Romneya Coulteri would grow with greater freedom in favoured places at home, producing more luxuriant foliage and possibly finer flowers, owing to a richer soil and moister climate. R. Coulteri flowers in May and June on the Riviera in the dry period. I have noticed that when shrubs are thriving on shallow soil they throw out side growths or "suckers," and are easily increased thereby. *Joseph Benbow, Dorchester.*

---

[*] According to Mädler (*Popular Astronomy*, p. 30), in the course of a year there are at the poles 41 hours more of day (all of which occurs in the summer half), 1,518 hours more of twilight, and 1,559 hours less of night than at the equator.

[*] Sir W. Thiselton Dyer in *Gard. Chron.*, May 15, 1897

Daphne Laureola.—Last year the readers of *The Gardeners' Chronicle* were asked to return this spring to the subject of the presence of scent in the flowers of Daphne Laureola, so here is my experience. It has been growing in this garden for many years in clay soil that has been well-worked and fed in days gone by for the sake of neighbouring Roses. The plant has no objection to the drip from a good-sized Maple that overshadows it. No one knows whence the shrub came from originally—it just appeared. The flowers have no vestige of perfume at any stage, and never have had. The plant always blooms before Daphne Mezereum, which is only now showing colour in the buds. *E. T. M., Ealing, January* 26.

Arauja sericifera.—Regarding Mr. C. Nicholson's note on p. 488, vol. LXXVIII, referring to my previous note on the "Potherb," and "Vapourer" moth, my Potherb moth is Hadena oleracea (La Patagire), as given by Dr. Paul Girod in his *Butterflies of France.* It is extremely abundant from early spring to late autumn along the whole Riviera. Regarding the "Vapourer," of course, I was wrong, and I quoted it because I habitually class these two moths as our worst enemies. My sons obtained several species from the flowers of Arauja during the past two seasons, but fail to identify them now amongst our collection. This season we will carefully note all the species we find, which may be of interest. I venture to suggest that occasional notes on moths and butterflies would be read with great pleasure by very many subscribers to *The Gardeners' Chronicle. F. W. Smith.*

Aucuba japonica variegata.—I am grateful to Mr. Comber for his note (p. 44), concerning the above species. He is quite right in thinking that I had regarded the variegation of the leaves as an indication of sex. How could it be otherwise when all the green shrubs I have examined were female, and all the variegated shrubs, male? The discussion has established the point that such is not the case. We have, in support of this, the experience of Mr. Comber extending over fifty years, and the statement of Mr. Bean in his book *Trees and Shrubs Hardy in the British Isles.* It remains to me now to bring the point established within the range of my own personal observation. For that purpose I hope to make a pilgrimage to Roath Park, Cardiff, when the shrubs which formed the subject of my original note are in bloom It is a matter for regret, I think, that Mr. Comber did not examine the flowers of the variegated Aucubas which he first observed twenty-five years ago. He might then have been able to answer my question: "Is the Spotted Laurel losing its dioecious character?" for he might have found that a bisexual flower preceded the occasional berries. *Geo. H. Copley, N.D.H.*

Perpetual-flowering Carnations.—I agree with Mr. Howard Grace (see p. 51) as to the necessity of obtaining fresh stock of Perpetual-flowering Carnations. With care, one can raise good stock from cuttings that are weak, provided they are procured from plants that are clean and healthy. Whilst it is desirable to propagate these Carnations from strong, clean, healthy specimens, it is not easy to do so in every case, as certain varieties are naturally weak in constitution. The stock under my charge here runs well into four figures and is in a clean and healthy condition. I have propagated many varieties for years in succession and they still retain their good qualities. By careful selection of the plants when in flower, choosing the best for obtaining cuttings, I have never failed to secure good flowering plants. As regards temperature, I find that from 50° to 55° with a corresponding rise during sunshine is suitable, sufficient fire-heat being maintained in cold, damp weather to permit of opening the top and side ventilators, more or less, according to the weather. I never syringe the plants unless forced to do so, as I consider it destroys the "bloom" on the foliage. *W. M. Foulds, Cromlix, Dunblane.*

SOCIETIES.

NATIONAL CHRYSANTHEMUM.

ALTHOUGH there were few members present to hear it the Committee of the National Chrysanthemum Society had the pleasure of reporting a pleasant state of affairs at the Annual General Meeting held at Essex Hall, Strand, on the 1st inst. Mr. E. F. Hawes presided and others present included Mr. D. Ingamells, Mr. H. J. Jones, Mr. B. Carpenter, Mr. J. B. Linford, M. Falkner, Mr. Goddard, Mr. A. R. Crick, Mr. D. B. Crane, Mr. W. Newton, Mr. Runcieman, Mr. Emberson, Mr. M. E. Mills and Mr. Thos. Stevenson.

The Annual Report and Accounts were read by the Secretary, Mr. C. H. Curtis. In the former, reference was made to the fine show held in November last, when the Royal Horticultural Society's hall was very crowded with visitors and £86 6s. 6d. was taken at the doors. The Floral Committee considered the merits of 116 varieties of Chrysanthemums and granted thirty-six First Class Certificates and three Commendations. The loss sustained by the death of Mr. C. Harman Payne received sympathetic mention—"His association with the National Chrysanthemum Society extended over a period of about fifty years, and for thirty-six years he was the Society's foreign corresponding secretary. He was a gifted man, a good speaker, a clever writer, and he possessed the saving grace of humour in a marked degree."

The Committee reported an arrangement to hold a competition for early-flowering Chrysanthemums at Vincent Square on October 5 next, and a proposal to provide larger show boards for Japanese blooms in one of the classes at the show in November next. These will be by way of experiment, and there will be ten inches from centre to centre of the holes for the flowers.

The financial success of the year 1925 was very marked, the turnover being about £100 more than in 1924. Subscriptions amounted to £98 8s.; Floral Committee fees to £5 16s.; and special prizes £92 13s. 6d. The total receipts at the November show, including competitors' fees, tickets sold, and gate money came to £98 4s. The entire, receipts including the balance from 1924, amounted to £407 7s. 10d. The expenses of the November show came to £164 9s., and on this sum £147 3s. 6d. was paid out in prize money. Printing and stationery cost £40 3s. 3d., while hire of rooms, secretary's salary, postages and carriage totalled £62 16s. 6d. The committee placed £50 on deposit, thus bringing the reserve fund to £100, and carried forward a balance of £34 8s. 8d. The balance sheet showed assets amounting to £161 14s. 8d., liabilities £1 1s., leaving a balance of £160 13s. 8d.

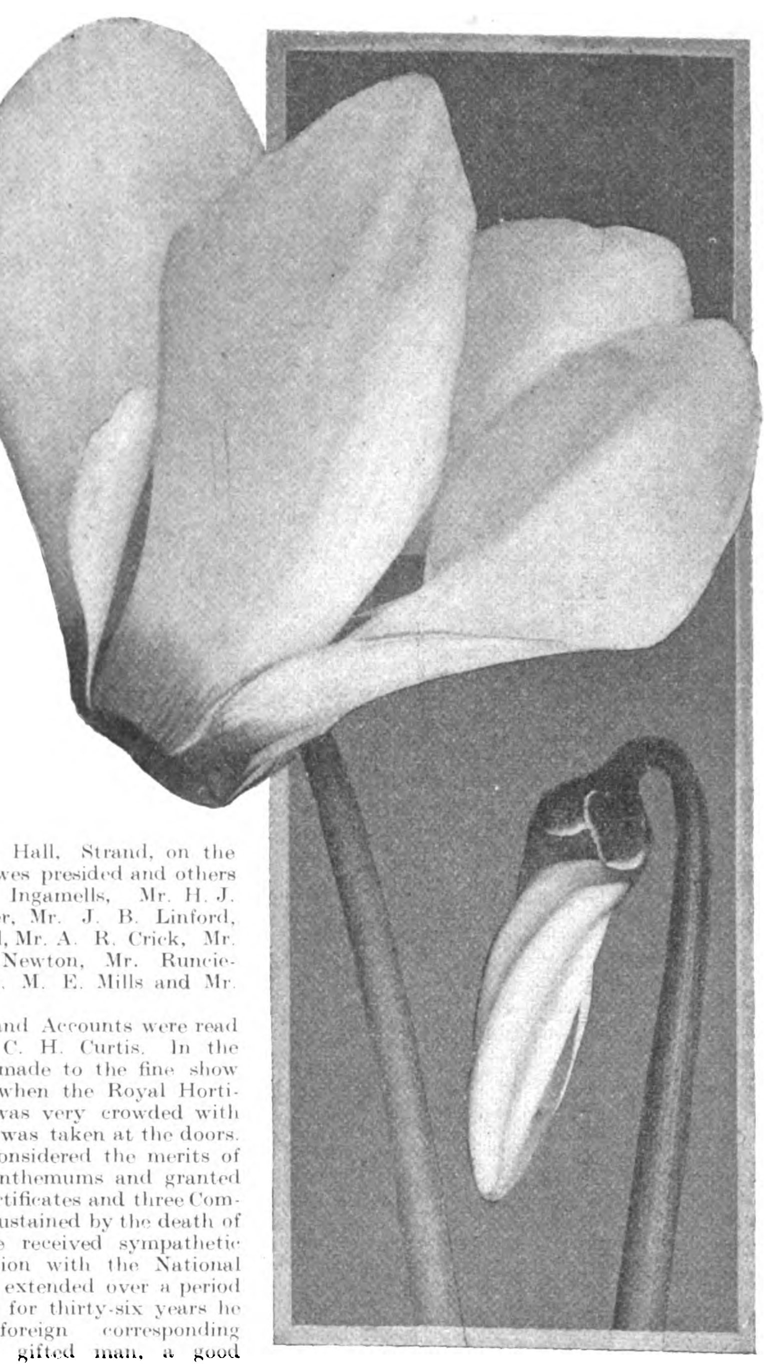

FIG. 53.—CYCLAMEN GIANT SHELL PINK.

(see p. 104)

The Chairman moved the adoption of the report and accounts, which Mr. D. Ingamells seconded; both referred to the excellent position of the Society and made reference to the generous support given by Sir Jeremiah Colman and other friends. The motion was carried. Mr. A. R. Crick proposed and Mr. T. Stevenson seconded a vote of thanks to officers and committee. Mr. Cross moved and Mr. Mills seconded the proposal that special thanks be tendered to Sir Jeremiah Colman, Bt., that the sympathy of the members be sent him relative to his recent accident, and that he be asked to continue as President of the

Society for 1926; the proposal was carried with unanimity and acclamation.

The following officers were re-elected: Chairman of Committee, Mr. E. F. Hawes; Hon. Treasurer and Vice-chairman of Committee, Mr. David Ingamells; Hon. Auditors, Messrs. R. A. Witty and S. Bayly; Secretary and Editor, Mr. Charles H. Curtis. Messrs. A. C. Bartlett, P. A. Cragg, D. B. Crane, A. J. Foster, M. E. Mills, W. Newton, G. Prickett, Mr. A. Robertson, Mr. W. Roots, and Mr. Thos. Stevenson, who retire by rotation, were re-elected members of Committee to retire in 1929, and Capt. Wright and Mr. A. R. Crick were elected to fill vacancies arising. The members voted £5 to Mrs. Curtis as a small token of their appreciation of services rendered at the November Show.

At the conclusion of the general business Mr F. Stevenson gave a short informal talk on his visit to the United States and stated that the cultivation of Chrysanthemums was carried out over there on entirely different lines to ours. In most places the plants were struck late, and planted late on benches in three or four inches of soil, and often not more than six inches apart. They were grown under much warmer conditions than in this country, but they produced fine blooms which, however, had fewer florets than those grown in England. Mr. Stevenson's observations were greatly appreciated and it was agreed that a paper or talk on some relevant subject would greatly add to the interest of the annual meeting and probably induce others to attend.

A vote of thanks to the Chairman concluded the proceedings.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

A GOOD muster of supporters of this useful charity attended the annual meeting and election of new beneficiaries, held at Simpson's, 101, Strand, on Tuesday, the 26th ult. In the unavoidable absence of Mr. Leonard Sutton, Mr. A. J. Wood was elected to preside. Those present included Mr. J. F. McLeod, Mr. D. Ingamells, Mr. E. G. Monro, Mr. Noel Sutton, Mr. P. White, Mr. P. C. M. Veitch, Mr. Chas. H. Curtis, Mr. J. Bullock, Mr. A. Dye, Mr. H. G. Cox, Mr. James Hudson, Mr. W. A. Bilney, Mr. P. R. Barr, Mr. J. B. Lintord, Mr. Bernard Crisp, Mr. A. Dawkins and Mr. R. F. Felton.

Following the notice of meeting and the reading of the minutes of the previous annual general meeting, the Secretary, Mr. George J. Ingram, read the annual report of the committee and presented the audited accounts for 1925. From the former we make the following extracts.

EXTRACTS FROM COMMITTEES' REPORT.

BEFORE presenting their annual statement, the Committee desire to place on record an expression of their heartfelt sorrow and respectful sympathy at the loss they and the Institution have sustained by the lamented death of Queen Alexandra. Her late Majesty had been a beloved patroness of the charity for forty years, and had always evinced a gracious interest in its activities and needs besides being a liberal contributor to the funds of the Institution. Her late Majesty was pleased each year to allocate a portion of the proceeds derived from "Alexandra Day" to its funds' behalf, for which the Committee have always been most grateful.

The Committee have again to express their cordial thanks for the practical support they have continued to receive which has enabled them to maintain the work of assisting both permanently and temporarily a large number of poor old and distressed men and women who, in their day, did so much in ministering to the pleasures and necessities of all lovers of gardening. During the past year, several annuitants have passed away, of whom two left widows, and their cases having been considered and found deserving, they were immediately placed on the funds for the widows' allowance in accordance with Rule III. 13.

There are fifty-one approved candidates for the election this day, and the Committee recommend that twenty of these be elected. They regret being unable, in view of the financial uncertainties at the present time, to recommend a larger number. Fortunately, the unsuccessful candidates who have been subscribers will be assisted whilst awaiting election by grants from the Victorian Era Fund, in amounts *pro rata* to the length of time they had subscribed, and others will be helped according to their need from the Good Samaritan Fund. Both these funds prove to be of incalculable value in assisting distressed cases. Although the annual income only from each fund is available for distribution, the Committee were able to assist fifty-one necessitous persons during the past year, and as the applications for temporary help are ever increasing, any special donations for either fund will be gratefully received.

The Eightieth Annual Festival Dinner on behalf of the fund was held, by the kind permission of the Master and Court of Assistant of the Worshipful Company of Grocers, in their beautiful hall, on July 2. The Rt. Hon. Sir Austen Chamberlain, K.G., presided, and eloquently advocated the claims of the Institution, which resulted in a substantial amount being raised in aid of the work, and the Committee desire to express their gratitude to Sir Austen Chamberlain for his great kindness and material aid to the Institution. They also offer their warmest thanks to the Worshipful Company of Grocers for the use of their hall and for the generous donation to the Chairman's list in aid of the funds. Their cordial thanks are also given to those gentlemen who acted as stewards; to the donors of flowers, etc.; to the Horticultural Press, and to others who in any way contributed to the success of the Festival.

The Committee acknowledge with grateful and respectful thanks the renewed annual subscriptions from His Majesty the King (Patron) and His Royal Highness the Prince of Wales (President). Likewise to the following generous donors, viz.:—The Viscount Bearsted, the Lord Glendyne, Sir Jeremiah Colman, Bart.; Mr. Reginald Cory; Messrs. Rothschild and Son; Messrs. Hurst and Son; Messrs. Sutton and Sons; Major E. G. and Messrs. Geo. and B. J. Monro (including a further donation of £500 to the Geo. Monro Memorial Fund); The Royal Horticultural Society; Mr. Leonard Sutton, C.B.E; Messrs. Waterer, Sons and Crisp; Mr. A. J. Wood; Mr. F. J. Chittenden, V.M.H.; Mr. P. C. M. Veitch, V.M.H.; Mr. Edward White, V.M.H.; Mr. H. G. Alexander; and Mr. Peter R. Barr; and the Committee are deeply indebted to the Rt. Hon. Viscount St. Cyres; the Rt. Hon. Earl Beauchamp; the Rt. Hon. Lord Northbourne; the Lady Battersea; Mr. C. W. Dyson Perrins, J.P., and Mr. Roger Corbett, J.P., for so kindly again allowing their beautiful gardens to be opened to the public for the benefit of the Institution.

It is desired to acknowledge the kindness of the promoters and organisers of concerts and other functions, amongst whom may be specially mentioned: Mr. Thomas Cook, Sandringham; Mr. W. J. Auton, Woking; Mr. G. Wilson Fox, Wisley; The Geo. Monro, concert committee; Worcester Auxiliary Branch; Liverpool Auxiliary Branch, and the Altrincham and District Gardeners' Improvement Society. Grateful thanks are also tendered to Messrs. Ralph Bond, Veitch and Bilney (hon. solicitors), and to Messrs. Geo. Cobley, Kay and Co. (chartered accountants), for their kind and gratuitous services. To the Honorary Officers and the Committees of auxiliaries at Bristol, Worcester, Exeter, Reading and Liverpool, the Committee express their gratitude for the continued practical and valuable services so keenly appreciated.

With the deepest regret the Committee have to report the loss by death of many supporters during the past year. Amongst whom were:—The Lord Barrymore; Mr. Arthur W. Sutton, F.L.S., V.M.H. (for many years a valued member of Committee and a generous subscriber); Mr. Heber Mardon; Mr. A. B. Hollinsworth; Mr. Percival Etheridge; Mr. Whitpaine Nutting; Mr. John Heal, V.M.H.; and Mr. George Bradley. These warm-hearted friends and liberal contributors will be greatly missed.

A special general meeting of subscribers was held on October 20, 1925, for the purpose of appointing a new Trustee of the Institution, when Mr. Bernard Woodward Crisp was unanimously elected.

In concluding this brief summary of the work, the Committee again thankfully acknowledge the kind and liberal support which has hitherto been given to this National Horticultural Charity for a period of eighty-six years, and for a continuance of which they very earnestly plead, so that the good work may be maintained with undiminished effort.

LEONARD SUTTON,
Chairman of Committee.

GEORGE J. INGRAM,
Secretary.

The Chairman moved the adoption of the report and accounts, and in so doing paid tribute to the work done for the charity by Mr. Leonard Sutton, who, owing to a prior and important engagement could not be present, but whom, they were glad to know, had now recovered from his illness. Mr. P. White seconded the motion, and it was carried.

Mr. Edward Sherwood was unanimously elected Treasurer on the motion of Mr. Wood, and Mr. McLeod. In proposing the reappointment of Mr. George J. Ingram as Secretary, Mr. E. G. Monro said that thirty-five years ago, almost to a day, his father proposed Mr. Ingram as secretary with the observation that the members would never regret the appointment. His father was right, and they felt that Mr. Ingram was unusually well-fitted for the position. Mr. Felton seconded the proposal, and it was carried with applause.

Mr. Curtis proposed the re-election of Mr. H. G. Alexander, Mr. W. Atkinson, Mr. A. F. Barnes, Mr. Peter R. Barr, Mr. Peter Blair, Mr. E. A. Bunyard, Mr. R. J. Cuthbert, Major E. G. Monro and Mr. H. W. W. Nutting, as members of committee, and the appointment of Mr. Charles H. Cook, Royal Gardens, Windsor, in place of Mr. C. R. Fielder, retired. This was seconded by Mr. P. C. M. Veitch and carried. On the motion of Mr. Hudson and Mr. Bernard Crisp, the arbitrators were re-elected. Mr. Veitch moved and Mr. Bullock seconded a vote of thanks to Mr. Thomas Manning, Mr. P. R. Barr and Messrs. George Cobley, Kay and Co., as auditors, and their re-election.

* £1,250 is required to meet the Quarterly payments due on December 31, 1925.

† Includes (*a*) £920 for investment "Geo. Monro Memorial Fund."
(*b*) part for investment in commemoration of H.R.H. Prince of Wales' Presidency at Festival 1924.

We have examined the Accounts of Receipts and Payments with the Books and Vouchers, and we certify that, to the best of our information, they are correct. We have also verified the investments and bank balances of the Institution.

(Signed) GEORGE COBLEY KAY & CO.
Chartered Accountants.

Messrs. E. G. Monro, H. G. Cox, P. White and D. Ingamells were appointed scrutineers of the ballot, and the meeting was then adjourned until the declaration of the poll.

The large number of votes recorded gave the scrutineers a great deal of work, and they could not complete their task until past five o'clock. The result of the poll was published on p. 73 of our issue of January 30.

After the declaration of the poll Mr. R. F. Felton asked the Committee to accept two-thirds of the profits of the sales during the second, third and fourth days of the opening of his new flower shop at Devonshire House, Piccadilly. He proposed to divide the remaining one-third between the Royal Gardeners' Orphan Fund and the Blind Gardeners. The Chairman said the matter would come before the Committee and he felt sure Mr. Felton's kind offer would be accepted.

Thanks to the scrutineers and to Mr. A. J. Wood for presiding, moved by Mr. W. A. Bilney, brought the proceedings to a close.

BRITISH FLORISTS' FEDERATION.

ABOUT three dozen members met under the Presidency of Mr. A. W. Ladds on the occasion of the annual general meeting of the British Florists' Federation, at the Holborn Restaurant, during the afternoon of January 29. Several members brought friends with them to listen to the discussion after the general business, and five of these subsequently signified their intention of becoming members.

The report of the Committee and the audited accounts for 1925 were presented formally, and as they had been circulated to members they were taken as read.

From the former we gather that representatives of the B.F.F. took their part in the investigations into the subject of the economic heating of greenhouses, in conjunction with representatives of the Lea Valley Growers, and that the Federation's share of the costs came to £35, this sum being generously contributed by members who were specially interested. The Federation was also represented at Haarlem at the annual conference of the Fédération Horticole Professionnelle Internationale, and did their best to obtain the removal of the present duty imposed by France on British flowers, urging that there was no tax on French flowers imported into Great Britain. The work of the Market Committee and the Market Floral Committee was reviewed and we were glad to find that the latter committee is very sparing with its awards. The Committee emphasised the need for maintaining a strong association in the interests of the flower trade.

The following extract briefly sets forth the work accomplished :—"The Committee would remind growers especially that during the latter part of the war period the Federation was able to preserve the industry from extinction by meeting the Government's proposals with counter-proposals, and by promising the hearty co-operation of growers in the production of food, provided the cut flower and pot plant industry could be maintained in such a degree as would enable those engaged in it to re-establish themselves quickly so soon as circumstances permitted. In regard to the transport of flowers and plants by rail, the Federation was mainly instrumental in obtaining conditions and rates which proved of immense value to the whole horticultural trade. Further, the Federation secured better conditions for those who sell flowers and plants in Covent Garden Flower Market—the great distributing centre—and by this means effected a saving of many pounds sterling per year by the standholders. The Federation also suggested the present site of the Foreign Flower Market, and, later, used its influence successfully to secure easier terms for the standholders in this section. These are a few items of the work done, and they are sufficient to show that the Federation has amply justified its existence and deserves greater support. It is far better that the cut flower industry should have a strongly supported Federation, in being, to meet and resolve the difficulties as they arise—and there are several that may arise in the near future—than have to reconstruct one hastily in cases of dire need and emergency. The officers and committee who give time and money to help their fellows, have a right to expect more support than they receive at present. That support can be given by the prompt payment of annual subscriptions and by an earnest effort to obtain new members."

The accounts showed a turnover of £229 18s., the income from subscriptions amounting to £191 8s. 6d. The balance carried forward was £2 18s. 10d.

Mr. Ladds, in moving the adoption of the report and accounts, referred to his year of office as a somewhat lean one, and regretted there had been nothing to fight about, nevertheless, there were prospects of difficulties arising, therefore there was need for the Federation and need for more members. Mr. Engelmann seconded the motion and it was carried. On the proposal of Mr. Ward, seconded by Mr. J. Page, the officers and committee were thanked for their services. The next business was the election of President for 1926, and Mr. G. Shawyer proposed Mr. David Ingamells for that position, pointing out that during three years Mr. Ingamells had refused that office because he did not want members to feel the Federation was solely a Covent Garden affair. He referred to Mr. Ingamell's work in various ways, and especially in connection with Covent Garden, and he hoped the election would be unanimous. Mr. E. W. Wallace seconded the proposal, and spoke very highly of Mr. Ingamells' ability and usefulness to members. The proposal was adopted with applause, and Mr. Ladds then vacated the chair in favour of the new president, who at once proposed a vote of thanks to the retiring president a vote which was accorded with great heartiness.

Mr. Windle proposed and Mr. Brookhouse seconded the motion for the re-election of Messrs. C. Harding, H. G. Mount, George Monro, George Shawyer, G. W. Leak, and H. T. Mason, due to retire by rotation, and the appointment of Mr. F. Segar to fill a vacancy caused by the retirement of his father. This was agreed. The appointment of Messrs. George Cobley, Kay and Co., Southampton Street, W.C., as hon. auditors, and thanks to them for past services, concluded the general business.

The President then called upon Mr. J. Windle to open a discussion on Flower Imports. Mr. Windle said he brought the matter forward in the interest of British growers who, in his opinion, were being crowded out by the dumping of foreign flowers. America had placed an embargo on imported plants, and Holland was increasing her exports of flowers to this country ; not only did she sell bulbs but she exported flowers also. Germany had put up a big tariff wall against flower and plant imports, and he gave figures, subsequently corrected by Mr. Englemann, which showed that she was imposing a duty of 10/- per cwt. on bulbs, 50/- per cwt. on cut flowers ; 12/6 to 37/6 on foliage ; 10/- on pot plants ; 12/6 on plants without soil ; 20/- per cwt. on Rose trees ; and 15/- per cwt. on other plants. He did not blame the German Government for imposing these duties, but he considered our own Government should also impose duties to protect the home grower. France, which he designated as the "dumper in chief," exported to this country flowers and plants to the value of £200,044 in 1924, which came in free of duty, and yet France imposed a duty on choice flowers exported to it from England. He concluded by stating that it must be obvious that this country cannot absorb the heavy supplies of flowers that are coming from France and Holland without doing great injury to the British grower, who is compelled to pay standard wages with limited hours of labour, and he advised the trade to apply for protection under the Safeguarding of Industries Act, "to grow British, sell British and buy British."

A very interesting discussion followed in which Mr. George Shawyer, Mr. F. W. Ladds, Mr. W. H. Page, Mr. R. H. Page, Mr. Jolis, Mr. Felton, Mr. Engelmann, Mr. H. T. Mason and others joined. There was, of course, a diversity of opinion on the subject, but it was pointed out that Holland purchased woollen and steel goods from us and that we ourselves were the largest exporters in the world. Eventually the subject was remitted to the general committee for further consideration and for action as seemed desirable, but the general opinion seemed to be that the imports of French flowers during winter served a very useful purpose, and kept the florists' businesses alive.

A hearty vote of thanks was accorded to Mr. Windle for opening the discussion, and after some observations on the subject of refrigeration of flowers, the proceedings closed with a vote of thanks to the president.

Later in the evening a company of nearly ninety members and friends, including ladies, dined together under the presidency of Mr. David Ingamells. The tables were brightly decorated with Golden Spur Daffodils.

The programme included a number of musical items, and the following toasts :—"The British Florists' Federation," proposed by Mr. A. A. Fincham, who made a capital speech, eulogising the work of the Federation, and responded to by the President ; "The Men, the Market and the Flowers," proposed by Mr. W. E. Wallace and responded to humorously by Mr. F. W. Ladds ; "The Ladies," proposed by Mr. H. Miles, junr., and responded to by Mrs. W. E. Wallace ; "The Visitors," proposed by Mr. Thos. Stevenson, to which Mr. H. Mason replied. "The President," proposed by Mr. W. Robins, and accorded musical honours, concluded a very pleasant evening's entertainment that was much appreciated after the business of the afternoon.

Obituary.

James Whytock, V.M.H.—The death is announced of Mr. James Whytock who was formerly gardener to the Duke of Buccleugh at Dalkeith and who retired in 1921 after twenty-one years service. Deceased occupied a foremost place in the horticultural world. For a number of years he was President of the Scottish Agricultural Society and in 1914 he was presented by the Royal Horticultural Society with the Victoria Medal and was made a fellow of that institution. For four years he was President of the Botanical Society of Edinburgh, in which city he resided until his demise on Sunday last.

Edwin Sidney Wiles.—Mr. E. S. Wiles, who passed away on January 21, in his seventy-seventh year, was gardener at Edgcote Park, Banbury, Oxon, for thirteen years (1878 to 1891), and during that time became a successful raiser and exhibitor of Potatos. It was while at Edgcote Park that he brought out the variety Edgcote Purple and other noted sorts. After leaving Edgcote Park he carried on a business at Oxford for a few years, and later went as gardener to the Hon. Evelyn Hubbard, The Rookery, Downe, Kent. He was in charge of those gardens for thirteen years, and during that time continued his activities with Potatos and other vegetables. After the sale of the Rookery he moved to Knowle Hill Park, Cobham, Surrey, and for three years had charge of the gardens there, until the sale of the property. His next appointment was as gardener to the Branksome Tower Hotel, Ltd., Bournemouth, where he remained five years before becoming gardener at The Dene, Totton, Hampshire. Here he carried out his duties for three years, when he met with an accident which deprived him of his sight. He then went to reside at Upper Parkstone, Dorset. He learned to read books printed in Braille, and gained a certificate from the National Institute for the Blind. He maintained his cheerfulness for five years under great difficulties. Death was due to heart failure. Mr. Wiles leaves a widow, one son and two daughters to mourn his loss.

MARKETS.

COVENT GARDEN, Tuesday February 2nd, 1926.

Fruit: Wholesale Average Prices.

—Peaches, per box	4 0—8 0
—Pears	4 0—7 0
—Plums	5 0—8 0
—Others	4 0—5 0
S. A. Pears	3 0—5 0

REMARKS.—The volume of business being transacted is extremely good for the time of year. Imports of fruits from South Africa, consisting of Peaches, Nectarines, Pears and Plums, are assuming large proportions; the various subjects are arriving in good condition and meeting a good demand. The Apple trade is moderately good, with home-grown Apples in demand, but only if of first grade. Hothouse Grapes are still available, mainly from Belgium. Grape Fruits are fairly plentiful and quoted at reasonable prices. Oranges show little fluctuation in value as compared with last week. French Beans are inquired for, although they are very dear. Asparagus, principally from France, has been selling very well, but at the time of writing there is an easier tendency. English Asparagus (forced) has also improved in price. New Potatos from Guernsey are selling well, but although there is a slight improvement in the trade for new Potatos from the Azores, Canary Islands and Algeria, the demand is still quiet. Mushrooms are a steady business, with supplies showing a gradual increase. Forced Rhubarb has sold slowly, even at low figures; some improvement is looked for in this section. Beans from Madeira arrived in good condition and have sold well. Cauliflowers from northern France are a firm trade, as also are Lettuces from the south of France. Tomatos from the Canary Islands have shown a better business, with higher prices. Bananas from the same source are also a fair trade. Green vegetables are not cheap. Fair supplies of old Potatos are offered, good samples meeting a fair enquiry.

Violets	4 0—6 0

REMARKS.—Daffodils from home growers are still retaining their prices owing to a steady supply. Golden Spur is the most plentiful. Double Van Zion is receiving more attention from buyers owing to the fine quality of the blooms. A few princeps and King Alfred are the newest arrivals. Almost daily consignments of these blooms are being received from the Channel Islands, also increased supplies of Narcissus Grand Primo, N. Soliel d'Or and Scilly White, Anemone St. Brigid, Anemone fulgens, Freesias, Violets and Snowdrops. Tulips have increased in quantity, both double and single varieties, and their quality is exceptionally good. Large consignments of these blooms are coming from Holland, the quantity exceeding the present demand. Chrysanthemums are gradually decreasing in numbers, and their prices are firmer; a few bronze and yellow blooms are in moderate demand. Of Roses, the only sorts to be recommended are a few blooms of Columbia and Premier at 15/- and 18/- per dozen. A few blooms of Richmond, of the new crop, came to hand last week, but the stems were very short. Carnations are good in quality and cheaper owing to the poor demand. There is a glut of English Violets, whilst Snowdrops are increasing in quantity daily. The consignments of French flowers have been heavier since Friday last, and prices are on the down grade. Anemones, Ranunculus and Marguerites, which were greatly affected by the severe weather, are now recovering in quality. There is a good demand for these blooms. Acacia (Mimosa), Narcissus Paper White and Single Violets are being despatched to the provinces in large quantities.

GLASGOW.

The cut flower market was featureless during the past week. Business was on a moderate scale, and movements in prices were mostly in a downward direction. Values in Tulips were all in favour of buyers, and work out as follows:—Bartigon and William Pitt, 1/6 to 2/3 for 6's; Ibis, 1/2 to 1/5; Couronne d'Or, 1/- to 1/4; Rosini and Rose Tendre, 1/4 to 1/6; W. Copland, Tea Rose and Flamingo, 1/- to 1/2; Vermilion Brilliant, 10d. to 1/-; Prince of Austria and Murillo, 9d. to 1/-; Thomas Moore and La Reine, 8d. to 1/-. Daffodils were also cheaper at 10d. to 1/- for Golden Spurs, 8d. to 10d. for princeps, and Van Sion, and 6d. to 8d. for ornatus. White Hyacinths made 8d. to 10d., and pink and blue, 9d. to 1/-. Special Narcissi were worth 4/- to 5/- per dozen, and ordinary 2/- to 3/-. Madame Butterfly Roses realised from 11/- to 14/- per dozen, while Carnations were cheaper at 3/6 to 5/-. Lilium longiflorum (Harrissii) advanced to 12/-, and Arums ranged from 7/- to 9/-. Lily-of-the-Valley sold at from 1/6 to 2/- per bunch; Mimosa, special, 6/- to 8/- per cane, ordinary, 4/- to 6/-; Smilax, 1/- to 1/6 per bunch, and Asparagus from 6d. to 1/-.

In the fruit market Jaffa Oranges further advanced to 17/- and 18/6 per case, while Valencia counts remained at former quotations. American Apples were also quietly steady at last week's prices. South African fruits were plentiful and cheaper, Peaches making from 4/6 to 6/- per tray; Nectarines, 5/- to 7/-; Plums, 5/- to 7/-; and Williams's Bon Chretien and Clapp's Favourite Pears, 5/- to 7/-. English Gros Colmar Grapes averaged 3/- to 3/6 per lb.; Scotch, 2/6 to 3/6; and Dutch, 1/8 to 2/6. Pines were worth 5/- each; and Rhubarb declined about 4/- per cwt. to 36/- and 38/-.

Vegetable prices moved within narrow limits. French Beans making from 4/- to 5/6 per box; Seakale, 2/3 to 2/9; Sprue, 1/- to 1/3; Endive, 3/- to 4/- per dozen. Lettuces, 1/6 to 1/9, and out-door grown Lettuces, 3/6 to 4/-.

GARDENING APPOINTMENTS.

Mr. A. Blake, previously Gardener to COL. WILDE, Danes Hill Gardens, Hertford, as Gardener to the same gentleman at Shenley Hill Gardens, Shenley, near Barnet, Hertfordshire.

Mr. James Cooke, for the past three years Gardener to R. V. BERKELEY, Esq., Spetchley Park, Worcester, as Gardener to the RIGHT HON. LORD BIDDULPH, Ledbury Park, Ledbury, Herefordshire.

Mr. F. Streeter, previously successor to the late Mr. F. BEDFORD at Straffan House Gardens, Co. Kildare, and recently at Wormley Bury, Broxbourne, as Gardener to the RT. HON. LORD LECONFIELDS Petworth Park, Sussex, commencing his new duties on March 25. (Thanks for 4/5 for R.G.O.F. Box.—EDS.).

ANSWERS TO CORRESPONDENTS.

CYPRIPEDIUM INSIGNE.—*Mack*. The proper time to pot plants of Cypripedium insigne is after they have flowered, and so soon as new growth commences. The pots should be well-drained, as this Orchid needs abundance of water when well-rooted and growing freely. A suitable compost consists of two parts moderately heavy fibrous loam and one-part of peat or half-decayed Oak or Beech leaves. To these materials should be added a little broken charcoal and sand, or finely crushed potsherds. Firm, but not hard, potting is desirable, and when potting is finished, the compost should be slightly below the edge of the rim of the pot, so as to allow space for water to be applied. The temperature for Cypripedium insigne should not fall below 40° in winter, otherwise a warm greenhouse temperature with plenty of atmospheric moisture will suit it.

DISEASED BULBS.—*T. W.* The small worms are the larvae of a fly, probably of a Bibionid. These flies are saprophytic and have not caused the rotting of the bulbs, which is probably due to the mites with which they are abundantly infested. It is probable, though not certain, that the mites were present in the bulbs when purchased.

EVERGREEN CLIMBING SHRUBS.—*F. F. W.* For a north wall Viburnum Tinus, Lonicera japonica, Euonymus radicans and Jasminum nudiflorum. The last named is not an evergreen, but the very numerous green twigs make it equal to an evergreen in value, and the plant is by far the best flowering climber for a north wall of a London garden. For a south wall, Escallonia langleyensis, Osmanthus Delavayi, Garrya elliptica, Ceanothus thyrsiflorus, Trachelospermum japonicum, and Choisya ternata may be selected.

HARES AND FRUIT TREES.—*A. F.* It is bad for trees, especially young trees, to have the bark covered with grease. We should be inclined to wipe off as much as possible and then wash the stems with warm water with some washing soda in it. The portions gnawed by the hare should then be dressed with grafting wax or painted with white lead paint or even tar.

NAMES OF PLANTS.—*L. W.* 1, Coelogyne cristata; 2, Chimonanthus fragrans. *G. K. P.* Sequoia sempervirens.

THE CHINKERICHEE.—*W. C. N., Middleburg.* The Chinkerichee is Ornithogalum thyrsoides a member of the Liliaceae. The flowers grow wild in South Africa, and are remarkable for their longevity.

WIRE NETTING FOR FRUIT TREES. *F. R. O.* For normal conditions, wire netting of three-quarters-of-an-inch mesh and No. 19 gauge is the most serviceable size to use in the construction of a bird-proof screen. If the structure is on a large scale, with supporting posts at wide intervals, it is preferable to use No. 18 gauge. The permanent exclusion of birds from fruit plantations is a distinct disadvantage and a more satisfactory means of obtaining protection when needed is to construct the sides of the area to be protected with wire netting, leaving the top open. If stout wires are run across the area overhead, in each direction, ordinary tarred netting may then be placed in position when the fruits are ripening. Should it be considered desirable to entirely enclose the area with wire netting the structure should be so arranged that occasional portions may be removed when the fruiting season is over.

Artificial Fertilizers.

THE systematic use of artificial fertilizers as a means of increasing crop production has not been practised for more than eighty years or so. True, liming of the soil is as old almost as agriculture itself, and readers of Chaucer will remember the jocund reference to the marl pit in one of the Canterbury Tales. But so far as the general use of fertilizers is concerned the year 1840 is memorable in that phosphatic manures—superphosphates—began then to be manufactured on a large scale for agricultural purposes. It was the great chemist Leibig who by his authority convinced the agricultural world that, as scientific men before him had shown, mineral substances—phosphates, salts of potash, and nitrates are essential to the life of plants. Inasmuch as experiments with plants showed that the roots can absorb only those substances which are soluble in water, or which become soluble when added to the soil, there was and is a natural tendency to measure the value of a fertilizer by the extent of its solubility in water. Needless to say this principle is a sound one—to the extent that if a substance added to the soil is and remains completely insoluble its direct value as a fertilizer is nil. Knowledge of the requirements of plants has, however, increased greatly in recent years. It is now known, for example, that the roots of plants flourish best when the soil solution, that is, the film-water which covers the innumerable soil particles, is very dilute. For example, it is estimated that the Wheat plant grows best when the soil solution contains no more than three parts of nutrient salts in 10,000 of water. A large increase above this figure not only does no good, but actually works harm; for it is true for roots as for mankind that enough is better than a feast. An excess of an indispensable nutrient substance is indeed harmful to the growth of plants. In the use of artificial manures some gardeners commit the mistake of "giving too little and asking too much," others err on the opposite side. But fortunately for them the soil possesses properties which tend to save them from the result of their liberality. Many substances when added to the soil are absorbed by it. That is, the particles of the substance stick with persistence to the soil particles with the consequence that if a soluble absorbable substance be added to the soil some of it is taken out of the solution and put, as it were, into the bank. Then as the root absorbs the material in solution the soil "bank" pays out more, and so on until the bank deposit is exhausted. Not all substances, however, are absorbed by soil. For example, sulphate of ammonia is absorbed, but nitrates are not. As a consequence of this behaviour it follows that it is good practice to add sulphate of ammonia at any convenient time to a soil that requires nitrogen, but that it is bad practice to add nitrate of soda, except at times when the actively growing plant can absorb it before rains have washed it out of reach of the roots. Needless to say there are other considerations to be taken into account in deciding which of these nitrogenous fertilizers to use. Thus there is ground for believing that as the ammonial constituents of sulphate of ammonia are absorbed by the roots the sulphate enters into combination with lime or such-like base and so reduces the alkalinity of the soil. On the other hand continued use of nitrate of soda adds to the soil alkalinity. Now it would appear that a good garden soil ought to be fairly neutral; neither too acid nor too alkaline, and, if so, it follows that it must be good practice for gardeners to ring the changes on the use of these two fertilizers, employing nitrate of soda and sulphate of ammonia alternately. Modern knowledge of the soil is likely to help growers in other directions also. The specially prepared phosphatic manures, for example, are somewhat costly. From the gardener's point of view this perhaps is no great matter, for in spite of their cost, such phosphatic fertilizers as bone meal, basic slag and, upon occasion and in certain soils, superphosphate, are all cheap to the gardener, that is, a moderate use of them amply repays and more than repays the outlay. Nevertheless where economy counts—and nowadays it counts or should count everywhere—there appears to be promise of an alternative and cheaper means of obtaining phosphatic manures. According to M. R. Avattaneo*, mineral phosphates, of which vast quantities are available, are by themselves too insoluble to serve as sources of phosphates to plants; yet if they are finely ground and well mixed with crude potassic fertilizers the solubility of rock phosphates is increased. Moreover, it is stated that the action is reciprocal and that the crude potassic fertilizer acquires also, by mixing with the rock phosphate, an increased solubility. If this be indeed the case then we should have ~~in the~~ mixture an ideal fertilizer so far as phosphates and potash are concerned. For an ideal fertilizer is one which gives to the plant enough and no more; undergoing solution but slowly, its contribution to soil fertility is more lasting than were it to enter rapidly into the soil solution.

* International Institute of Agriculture III, 3, 1925.

Export of British-grown Apples.—It may surprise some who are acquainted with the large imports of fruits from South Africa at this season to know that Cape Colony is a profitable market for English Apples. Mr. W. P. Seabrook, in an address before the Home Counties Market Growers' Association at Worthing recently, stated that we have been exporting, in a sort of hit or miss way, for some twenty years, hardy fruits to Cape Colony. Apples which were sent to Cape Colony at a cost of 5s. per box brought in a return of from 13s. to 15s. Last year, when Bramley's Seedling, Newton Wonder and Bismarck were realising 3s. 6d. to 5s. a bushel at Covent Garden, his firm was getting 13s. to 15s. home from Cape Colony. Mr. Seabrook stated that there were other markets open to our growers, including South Africa, Egypt and India, all of which offered very attractive outlets. He was careful to point out, however, that the best methods of packing and grading must be adopted and the fruits should be of good sample.

Town Botany in Winter.—Under the auspices of the Workers' Education Association, Professor J. Montagu Drummond, F.R.S.E., delivered the first of a series of four lectures on "Town Botany in Winter" in the Botany Department of Glasgow University on Saturday last. In dealing with "Seeds and Seedlings" he drew attention to certain features of winter vegetation in a large city and remarked that the question of hibernation or winter sleep of plants was most conveniently approached by a study of seeds and of the seedlings to which they gave rise. The structure of various common seeds, such as Broad Beans, Indian Corn, Onion, and Mustard, was explained by the aid of living specimens and lantern slides, while the relation of plants to light, gravity, and temperature was illustrated by means of various seedlings. Some unusual types of seedlings with special features of interest were also dealt with, and the general conclusion to be drawn was that the seed is a structure admirably adapted for the purpose of bringing the plant through an unfavourable period such as our winter, not only unharmed but ready to take advantage of the return of more genial conditions by a prompt resumption of active growth.

Royal Gardeners' Orphan Fund.—At the Annual General Meeting of the Royal Gardeners' Orphan Fund held on Wednesday last at Simpson's Restaurant, Strand, the following candidates were elected to the full benefits of the Fund by resolution:—Beatrice Bell, Williamina Bell, Elizabeth Edith Davis, Bella Gatley, Annie Gatley, Florence May Trebbie, and Maurice William Trebble.

Exports to Canada.—Mr. Leonard S. McLaine, Secretary, Destructive Insect and Pest Act Advisory Board, Ottawa, Canada, informs us that on May 4, 1925, a general memorandum was issued calling the attention of importers and shippers to the Order issued under the Animal Contagious Diseases Act in reference to the use of hay, straw and fodder, including Sphagnum Moss, as packing, on account of the foot and mouth disease. Several shipments of nursery stock have already been returned to the country of origin from the port of arrival in Canada on account of not being accompanied by the required certificate which must be attached to the ship's manifest. Importers are advised to notify their shippers of these requirements, and if further information is desired, a copy of the memorandum referred to can be obtained on request.

Nervous Reflex of Plants.—An account of the interesting botanical discoveries made by Sir Jagadis Chunder Bose is to be published in two volumes by Messrs. Longmans, Green and Co., who inform us that the first volume, dealing with the Nervous Reflex of Plants, is almost ready for publication.

Retirement of M. Viger.—After thirty years active occupation of the Presidential chair of the French National Horticultural Society, M. Albert Viger has retired, and has been created Honorary President of the Society. Few Presidents have shown more aptitude for their position, and M. Viger's resignation will be greatly regretted by all the members. Owing to his profound knowledge of all matters horticultural, and his scientific attainments, he grasped with ease the most difficult problems, and directed with mastery the many important congresses over which he presided. Nor is he less liked and respected in foreign countries, where he has represented French Horticultural interests at conferences and exhibitions. He carries with him the cordial good wishes of all who knew him, and it is devoutly to be hoped he will be in a position to preside at the centenary celebrations of his society, which will take place in 1927. He is to be succeeded in the active Presidency by M. Fernand David, whose portrait, together with a short biography, is published in the next column.

The American Florist.—Our contemporary, *The American Florist*, which claims to be the oldest floricultural paper in America, has reached us in an entirely new form. Formerly printed and published as a magazine it has now become a newspaper, with pages twenty-two inches long and fifteen inches wide. In general make-up it has adopted the style usual to American and many other newspapers, *i.e.*, big headlines and startling headings, and advertisements freely mixed with the text. It may be conservatism on our part, but we do not admire our old friend in its new dress, nevertheless, we offer our heartiest good wishes to the proprietors and staff on their enterprise, and trust the new venture will be entirely successful.

The Use of Paraffin in Gardens.—The note on p. 60 by Mr. Alfred Simeson on paraffin as a fungicide, pointing out its efficacy for a particular purpose is a good example of its general usefulness, and there is no doubt that paraffin is one of our most potent and useful specifics in the control of many pests. If every user would take the pains which Mr. Simeson advocates and emphasises, in its application, the use of paraffin would be more widely spread and less would be heard of harmful effects. The apparent improvement in the appearance of plants after the application of a paraffin wash, as noted, is probably due to its cleansing power, but it is probable that it not only acts as a cleanser of filth and destroyer of germs, but also makes the plant more resistant to the subsequent attack of pests, and this may be due to the slight coating of the sprayed plants with a more or less mineral film. Every one knows the difficulty of mixing water and paraffin, the laws of physics governing matter compelling the paraffin to float on the surface and, unless the mixture is kept constantly and actively agitated, the danger of getting more paraffin than is good for the plant is always present. But there is another and more subtle danger in that if used periodically on woody subjects harmful effects may result from the cumulative absorption of small quantities of paraffin by the tissues of the plant. It would appear that the absorption of a small quantity is harmless, but, like so many other mineral poisons and their action on living organic bodies, the cumulative effect of the continuous absorption of small quantities results in the final destruction of the living organism. It is common practice to dissolve soft soap in the water to facilitate the mixing of the paraffin with it, but this does not eliminate the danger, indeed, it may add to it, for although the water impregnated with soap holds the paraffin in suspension better than the clear water, the same physical law compels the paraffin to rise immediately the mixture is left unstirred, and whereas in the clear mixture the operator is prepared for this and sees it definitely, the tendency is to overlook it in the cloudy, soapy mixture. An emulsion of soft soap and paraffin, as made at Kew, by kneeding the soap in the paraffin, is quite safe to use.

M. Fernand David.—It gives us great pleasure to present to our readers this week the portrait of M. Fernand David, who has been elected President of the French National Horticultural Society in place of M. Viger, who has just retired after thirty years' occupation of this arduous position. The new President is fifty-six years of age, and has had a distinguished and active career. He has achieved much distinction in parliament, where he occupied the position of Senator for Haute-Savoie; he has been successively Minister of Commerce, Minister of Public Works, and, under no fewer than five different Governments, Minister of Agriculture. In all these positions his knowledge and energy have enabled him to serve with signal success the interests of his country in general and of agriculture in particular. In 1925, M. David undertook—it is well-known with what conspicuously successful results—the heavy task of Commissary General of the International Exhibition of Decorative Arts in Paris. The horticulturists who contributed such brilliant displays of their products to the exhibition greatly appreciated the tact, affability and perfect courtesy which they received from M. David. We feel convinced that the new President will use his outstanding qualities to the full in the service of the Society, and that it will benefit greatly from his excellent standing in official circles.

M. FERNAND DAVID.
New President of the French National Horticultural Society.

The "Mescal Button."—The daily Press reports the discovery of a peculiar narcotic plant called "Peyote," which is said to be "a rare species of Cactus found in Mexico." It is claimed that very small quantities of the juice of this plant when taken by human beings produces visions and clairvoyant powers. Dr. Rosehier, a French chemist, who with Dr. Osty, director of the Paris Metapsychic Institute, is reported to have conducted experiments with the plant, found that after taking small quantities of the juice the "subject has merely to shut his eyes and immediately a magic world of figures, animals, plants and beautiful stretches of landscape passes before him with the rapidity of a cinema film." Those partaking the juice are also said to be gifted with second sight, to be able to read the thoughts of persons near by and to rapidly solve abstruse problems. It is stated that the effects of this "wonder-plant" immediately pass off when the subject opens his eyes, and leaves no unpleasant after effects, as in the case of opium and other narcotics. This new discovery of the Daily Press apparently relates to the "Mescal Button" (Lophophora Williamsii), which in the Indian vernacular has a host of other names, including Peyote, and has long been used by the Indians in their religious rites. In the mountains of Mexico it is held in superstitious reverence by several tribes of Indians, and also in the United States. It does produce beautiful, highly-coloured visions, but its taste is bitter and disagreeable, while with some it induces violent vomiting. In some of its effects the use of the Mescal Button may be compared to hasheesh, except that instead of inducing merriment it produces a state of blissful content, often followed by insomnia. The Mescal Buttons are the dried tops of the Cactus, which, strung and offered for sale in the streets of Mexico, have much the appearance of Mushrooms.

Honour for Dr. L. H. Bailey.—The American Society for the Advancement of Science has chosen Dr. L. H. Bailey as its president. Dr. Bailey is best known in this country by reason of his numerous books on horticulture, and particularly his *Cyclopedia of Horticulture*, consisting of six large volumes. The Society which has elected him as President has a membership of fifteen thousand; he will not, however, commence his Presidency until December of the present year.

The Noxious Weeds Act.—At the instance of the Ministry of Agriculture a landowner of Selsdon, near Croydon, Surrey, was fined 40s. with £3 3s. costs for failing to obey an order to cut down or otherwise destroy weeds growing on land owned by him at Purley. Mr. Ward, for the Ministry, said that the land in question was vacant building land, and that private gardens in the vicinity had suffered from the spread of the weeds. Proceedings under the Noxious Weeds Act are comparatively few in this country, which is far behind other countries in the matter. In defence, it was stated that the owner's gardener had failed to carry out instructions given him last August.

An Example to Gardeners.—Everyone associated with horticulture should recognise the great need for assisting the two gardening charities—the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund. It will be seen on p. 106 that whilst the former institution had a list of fifty-one candidates whose claims to the benefits of the fund were recognised by the executive, the committee was only able to recommend twenty for election. These two charities exist solely for benefiting old and indigent gardeners and their widows, and the orphans of gardeners, and it is the duty of all professional gardeners in a position to do so, to help these charities by all that lies in their power. Mr. W. Auton, gardener to Viscount Elveden, of Pyrford Court, Woking, sets a notable example to his fellow gardeners, for during the past year he has raised no less that £102 which he has divided between the two charities. Even this is not all that Mr. Auton has done in the past twelve months for those in need, for, in addition, he has assisted his local parish nursing association to raise a sum of £40. By means of a rummage sale in conjunction with the Parish Nursing Association he was successful in obtaining £80, £40 of which was allotted to the Nursing Home and £40 to the gardening charities. He also held a successful whist drive which resulted in raising another £11, and by various other means, including collections, he brought his efforts for the year up to £142, of which the gardening charities, as stated, have received £102. Mr. Auton, who, like most gardeners, is a very busy man, sets a worthy example for other gardeners to follow, and shows what can be done by enthusiasm, enterprise and hard work.

Forestry in Scotland.—At the annual meeting of the Royal Scottish Arboricultural Society held at Edinburgh on the 3rd inst., Lord Lovat, Chairman of the Forestry Commissioners, gave some interesting particulars on the development of forestry in Scotland. Under the Forestry Commission scheme, stated Lord Lovat, the planted area at the end of the present planting season would amount to approximately 140,000 acres. Next year a further 22,000 acres would be planted, and in the following two years 26,000 and 30,000 acres respectively. Lord Lovat stated that the proportion of plantable to unplantable land which had been acquired in Scotland was distinctly disappointing. Out of 70,000 acres of specially selected deer forest only 18,000 acres were available for planting. Large tracts of land in northern Scotland were quite unsuited to tree growth, and practically the whole of Sunderland and Caithness fell under that category. Lord Lovat stated that the Forestry Commissioners hoped to be able in a comparatively short time to establish one or two paper pulp industries with a sufficient area of Spruce and Sitka Spruce woods to make a pulp industry possible.

Extraordinary Graft Hybrids.—Mr. F. W. Smith, Villa Nino, Eze-sur-mer, writes that an interesting notice regarding graft hybrids has appeared in *Le Chasseur Francais*, a journal which treats on many subjects, and has a wide monthly circulation. The writer signs himself *P. A., Subscriber*, and the following is a translation of his observations:—"We possess, in our garden, a Peach tree which bears fruits the form of which resembles exactly that of the Tomato, whilst the rest are that of the Peach, with this difference, that the perfume is much finer and the fruits are of a Muscat flavour. This fruit is very delicate, but exquisite. This result has been obtained by grafting the Tomato on to the Peach. Its author, who died several years ago has left us some curious graft, amongst others, a Cork Oak with two branches, one of which is a Medlar which produces perfect fruits. To those who doubt it, I can show them the Peach-Tomato. This tree is probably unique, and merits the attention of agriculturists." Mr. Smith adds: "Comment is needless, and I certainly shall not make any effort to inspect the Peach-Tomato (which may be a Nectarine fruit on a Peach tree), notwithstanding the invitation.

New Series of Potato Trials.—The National Institute of Agricultural Botany is now prepared to accept entries for its fifth series of yield and quality trials of new varieties of Potatos from breeders who are willing to entrust the Institute with the marketing of their productions on a profit-sharing basis. The trials are planned to last for five years, at first in Scotland only, but in the later years also in the English Potato districts. Only those varieties which do sufficiently well in the trials will be placed on the market. Full particulars of the conditions of the trials are given in a form of agreement which may be obtained from the Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge, to whom those intending to enter new varieties for these trials should apply not later than February 28, 1926.

National Carnation and Picotee Society and New Members.—At the general meeting of the National Carnation and Picotee Society, held on the 23rd ultimo, it was decided by the Committee that new members should receive a gift of plants upon joining the Society. Those subscribing the minimum subscription of five shillings are to receive five first-rate plants whilst those subscribing ten shillings and upwards will receive twelve plants. The Secretary of the Society, to whom application should be made for membership forms, is Mr. E. G. Lowe, 65, Exeter Road, Cricklewood, N.W.

Lanarkshire Potato Experiments.—Under the auspices of the Lanarkshire Education Authority in conjunction with the Glasgow and West of Scotland Agricultural College, a lecture on the results of the Hillhouse Demonstration Area, near Lanark, was delivered at Douglas Water, on Monday evening, by Mr. James McCutcheon, F.C.S. The chair was occupied by Mr. James McLaren, factor to the Earl of Home. In dealing with the Potato experiments the lecturer explained that the area was divided into six plots of half-an-acre, which had a uniform application of farmyard manure at the rate of sixteen tons per acre. The artificial manure differed either in quality or kind, but Mr. McCutcheon held that the ideal artificial manure was that used in plot six, consisting of three hundredweights of superphosphate, one-and-a-half hundredweight of sulphate of potash, and one hundredweight of sulphate of ammonia. The yield from this plot, it was explained, was not so great in quantity as some of the others, but the difference was more than made up in the quality. The total yields per acre of each variety were as follow:—White Rose, 12 tons, 16 cwts., 45 lb.; Di Vernon, 5 tons, 12 cwts., 40 lb.; Catriona, 1 ton, 17 cwts., 50 lb.; Miller's Beauty, 11 tons, 10 cwts., 53 lb.; Downe's Early, 7 tons, 12 cwts., 77 lb.; Rhoderick Dhu, 9 tons, 1 cwt., 42 lb. Kerr's Pink:—Plot 2, 13 tons, 6 cwts., 54 lb., Plot 3, 14 tons, 16 cwts., 82 lb.; Plot 4, 14 tons, 13 cwts., 96 lb.; Plot 5, 16 tons, 17 cwts., 8 lb. Plot 6, 14 tons, 16 cwts., 82 lb.

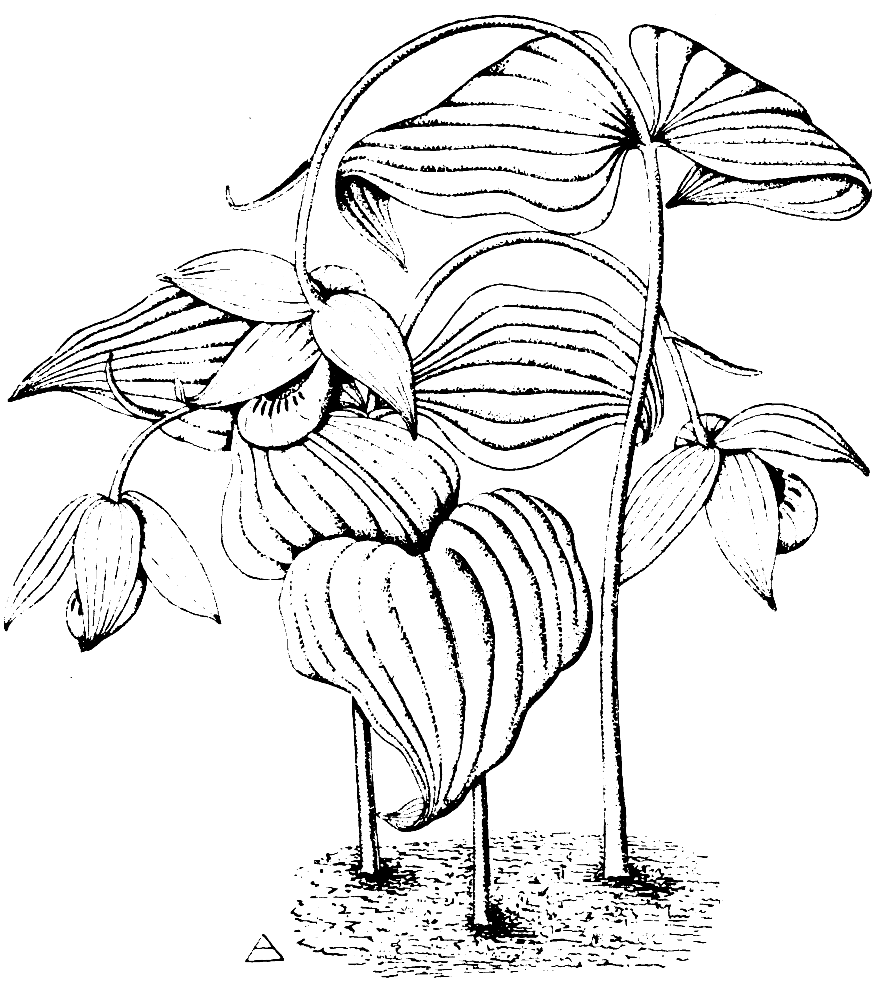

FIG. 54.—CYPRIPEDIUM DEBILE.

(see p. 114).

Gardens at the Ideal Home Exhibition.—Fifteen gardens are to be arranged in the annexe at Olympia on the occasion of the Ideal Homes Exhibition, which will be opened on March 2 and continue until March 27.

The Late Mr. James Whitton.—Mr. James Whitton, of Bellahouston House, Glasgow, for nearly thirty years Director of Parks and Gardens to the Glasgow Corporation, who died on October 30, left personal estate valued for probate at £6,955.

Appointments for the Ensuing Week.—Tuesday, February 16: Winchester Gardeners' Association meeting. Wednesday, February 17: Royal Gardeners' Orphan Fund Committee meeting; Pangbourne Gardeners' Mutual Improvement Association's meeting and lecture. Thursday, February 18: Crowthorne Horticultural Society's lecture. Friday, February 19: Manchester and North of England Orchid Society's meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Libocedrus Chiliensis, Endlicher (Thuja Chiliensis, Don)*.—A noble evergreen Conifer, a native of the Andes of Chili and the southern provinces of Antucco and Valdivia, growing to the height of sixty-five feet to eighty feet. Sir Wm. Hooker says: "It is a tree of great beauty, and well worthy of being introduced into our gardens. There can be little doubt, from its native regions (inhabiting the same elevations on the mountains as the Araucaria imbricata), that it will thrive well in the open ground." The following is an extract from a letter lately received from the well-known botanical collector, Mr. Bridges:—"In one of the late numbers of *The Gardeners' Chronicle* I see some doubts expressed relative to the Thuja Chiliensis being hardy in England. It will, in my opinion, be perfectly so, judging from what I have seen of the plant in the province of Colchagua, south lat. 35°, which is its most northern limit. It is found near the snow, and where it freezes, I should say quite as severely as it does in the vicinity of London. Where the tree grows alone it is very graceful, the lower boughs are even on the ground, and it elevates itself to a great height. The timber is esteemed by the natives for building purposes. I have myself seen it as far south as 42°, and I learn it is found in the vicinity of Cape Horn." Fine, healthy, well-established, one-year-old plants, from seed, in single pots, 7/6 each, three for 21/-, or £4 per dozen. Hugh Low and Co., Clapton Nursery, London. *Advertisement in Gard. Chron., February* 15, 1851.

Publication Received.—*Sweet Peas: Their History, Development, Culture*, by Chas. W. J. Unwin. W. Heffer and Sons, Ltd., Cambridge. Price, 5/- net.

The Week's Work.

THE ORCHID HOUSES.

By J. Collier, Gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

Cypripediums.—During recent years large numbers of hybrids of the cool-growing section of Cypripedium have been raised. This had the effect of extending the flowering season over a long period ; many of the plants commence to flower in November, and where moderate numbers are grown, a good display may be obtained well into the spring. No set time can be fixed for the necessary repotting of these plants ; a suitable time for the operation is shortly after the flowers have been removed, as fresh root action takes place at that period. Cypripediums, especially those of the C. insigne type and its hybrids, are of very easy culture, and are ideal plants for the amateur. Unlike many other Orchids, they are benefited by a fair amount of pot room. Better flowers are usually obtained from plants provided with ample rooting space than from those that are in a pot-bound condition.

Repotting Cypripediums.—When repotting has been decided on, the usual practice is to prepare a mixture consisting of equal parts of best fibrous loam, good English peat or Osmunda-fibre, broken rather roughly with all the earthy portions shaken out, some Sphagnum-moss and sufficient crushed crocks to render the mixture porous. The receptacles should be filled to one-third their depth with material for drainage, and the drainage in turn should be covered with a thin layer of coarse soil. The plants, especially those that are very pot-bound, should be watered copiously a day before being disturbed. After taking the plants from the pots, remove the drainage material and all exhausted soil from between the roots, cutting away all decayed portions of the latter. Place the plants in the pot, spread out the roots and work the compost firmly between them, filling the pot almost to the rim. If the soil is already moist these newly-potted plants will not require much water but will be benefited by light sprayings overhead. When the new roots have penetrated the soil, a liberal amount of water should be afforded them. Where a special house is devoted to this class of Cypripedium the temperature should range from 55° to 60°, and with sun-heat it may be allowed to rise 5° or 10°.

Potting.—With the advance of the present month the daily amount of light and sunshine will increase appreciably, and many Orchids will be showing renewed activity, both in their top growths and roots, therefore, plants that need re-potting or re-surfacing may be given attention from now onwards. The best time for the operation is when roots commence to develop from the bases of the young growths or the previous year's pseudo-bulbs. It is important that clean receptacles are used. These should be drained in such a manner that it is impossible for the compost to become waterlogged, as whatever material is used as a rooting medium, the question of watering needs great consideration and foresight, for the very best soil becomes sodden and sour if kept constantly wet.

FRUITS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Muscat Vines.—To have ripe Muscat of Alexandria Grapes in August the vinery should now be closed. Assuming the vines have enjoyed a period of rest, and the house in which they are grown has been thoroughly cleansed and the walls treated with lime-wash, the borders in which the vines are growing should be put in order. First remove the surface soil with great care so as not to injure the young, fibrous roots. After this has been done, if the border is dry soak it with tepid water before applying a top-dressing of new soil. The latter should consist of a mixture of rich, fibrous loam, coarse bone-meal and broken charcoal. Should the border need extending, as will be the case where young vines have been recently planted, this should receive attention now. I generally extend them about two feet each year until such time as they are completed, but much will depend on the strength of the vines under treatment. The drainage material should be arranged in position and carefully covered with two thin layers of fresh turves placed grass-side downwards. Add the new compost, building up the border with turves cut into four-inch squares. The compost should be in a fairly dry condition to permit of it being made moderately firm. This choice Grape requires a long season to finish its fruits and develop a rich amber colour in the berries. It is therefore advisable to start them now, but at the same time guard against overheating the water-pipes or the vines will break weakly and become infested with red spider. The foliage of Muscat Grapes is not so hardy as that of most other vines.

Vine Eyes.—If the planting of green vines during the summer is in contemplation, it is not too late to insert vine eyes. The easiest method of raising young vines is to sever the shoot with a sharp knife about one-and-a-half inch above and below the bud, then split the growth in halves and peg the part with the bud to the soil in a sloping direction with the bud uppermost. The pots containing the eyes may then be placed in a fairly brisk heat. In a very short time the buds will show signs of growth, when care is necessary to prevent damping. When it is found that the "eyes" have made sufficient roots, I strongly advise them to be grown in shallow boxes for summer planting. They are very easily transplanted when grown in this manner by removing one side of the box, moreover, the roots will extend over a larger area than those that are grown in pots. The soil for the border should be used in a fairly dry condition, and should be protected from heavy rains. In the case of cold, wet soils it is necessary to cement the bottom of the border, which should be made in a slanting direction to ensure water draining away freely from a properly prepared outlet. Drainage is best provided with rough, broken bricks over which should be placed a good layer of lime-rubble. The new border need not be more than three feet wide and about two feet deep. A good compost consists of two-thirds rich loam, the other third lime-rubble, bone-meal, and burnt garden refuse. The border should be made moderately firm, therefore the compost should be used in a fairly dry condition to permit of this being done.

THE KITCHEN GARDEN.

By F. Streeter, late Gardener to Major Albert Pam, Wormley Bury, Broxbourne.

Parsnips.—So soon as the ground is in a suitable condition, this crop should be sown. The seeds take a considerable time to germinate and the roots require a long season of growth to bring them to perfection. Drills should be drawn an inch deep and the rows made eighteen inches apart. Sow the seeds very thinly along the centre of the drill. Rake the soil and leave the bed as neat and tidy as possible. To obtain extra fine roots for exhibiting it is necessary to bore perfectly straight holes with an iron bar, three feet six inches to four feet deep, at a distance of twenty inches apart in rows two feet asunder. Fill the holes with finely-sifted soil prepared during inclement weather, make it moderately firm with a cane and leave a depression in the centre of the hole about an inch-and-a-half wide, in which place three seeds. Cover the seeds lightly with a fine, sandy compost. Fork the soil between the rows as the work proceeds, leaving all perfectly tidy. Tender and True, Maltese, Hollow Crown and The Student are excellent varieties.

Celery.—For very early work a small sowing of an early variety of Celery should now be made. Sow the seeds very thinly in well-drained pots containing a sandy compost, and germinate them in a temperature of 55° at night. So soon as the seedlings appear expose them to all the light available, and on no account allow them to become dry at the roots ; it is too early yet for sowing main crop Celery.

Parsley.—Where a difficulty is experienced in providing a good supply of Parsley through the winter, a box or two sown now and the seedlings raised in heat will give an early summer supply.

Spinach.—If a few old frames can be spared for the use of an early sowing of summer Spinach this vegetable will prove a most valuable addition in the early days of spring when choice vegetables are none too plentiful.

Paths, Drains, etc.—So soon as the work of trenching, digging and wheeling is finished, attend to the paths and drains. The latter are most important and should be always kept perfectly clean and in good working order. If gravel paths have become rough they should be turned with a fork and rolled level again. Watering and rolling gravel paths ensures a neat appearance with no loose stones, and the sweeping and cleaning of them is much more easily performed. Where the paths are of turf and kept mown, planks should always be used for wheeling upon them, otherwise the grass will be killed and the path made unsightly. Bare patches should be re-turfed as quickly as possible before the great rush of work in the next month.

PLANTS UNDER GLASS.

By John Coutts, Assistant Curator, Royal Botanic Gardens, Kew.

Exacum macranthum.—Although this beautiful plant is biennial, if seeds are sown now, there is no reason, given good cultivation, why the plants should not flower towards the end of the present year. Make another sowing in April or May ; the plants from this sowing should flower early next year. Where a stock of this plant already exists, it may be propagated by means of cuttings, which root readily in a warm propagating case. The fine seeds should be just covered with a sprinkling of sand and the seed pans with a piece of glass, shading the glass until germination takes place. Subsequent cultural details consist in pricking off the seedlings and potting them on as they require more root room, taking care not to overpot them at any time ; excellent plants may be flowered in forty-eight sized pots. Water should be afforded carefully at all times. This plant enjoys a warm, moist atmosphere of about 60°. The potting compost should be light and well-drained : it may consist of three parts medium loam, and the rest of good fibrous peat and sand. The successful cultivation of this species is by no means easy, but it is such a beautiful plant that it is worth all the care and skill the cultivator can bestow on it.

Statice Suworowii.—This Statice is useful for greenhouse decoration and should be much more generally grown. Seeds may now be sown in a temperature of 50° to 55°, and when fit to handle, prick off the young seedlings into pans or boxes of light soil, afterwards transferring them singly to small pots. When well-rooted, they should be placed in five-inch pots, in which they may be flowered. They grow freely in any good potting compost. Water should be afforded the roots carefully at all times. Later, a successional batch may be sown to flower towards the end of summer. Statice sinuata and S. Bonduellii, both annuals, are also useful for greenhouse decoration, and succeed under similar treatment to that recommended for S. Suworowii. There are several sub-shrubby species and varieties or hybrids which are excellent for greenhouse decoration ; S. arborescens, S. Bourgaei, S. brassicaefolia, S. imbricata and S. macrophylla, are all natives of the Canary Islands. They have blue or purple and white flowers. When seeds can be obtained, they are easily raised from them ; they are also propagated by means of cuttings or layers. S. Butcheri, S. Halfordii and S. profusa are hybrids or varieties of the species mentioned, and at one time were favourite subjects for growing into large specimens. They are ideal subjects for conservatory decoration, for which purpose they should be more generally grown, as they succeed perfectly in a cool greenhouse. They are subject to attacks of mealy bug, which must be guarded against.

HARDY FRUIT GARDEN.

By W. Auton, Gardener to Viscount Elveden, Pyrford Court, Woking, Surrey.

The Fruit Store.—Methodical and regular examination of the fruits in store should be made so that any fruits showing early signs of decay may be used and bad ones removed. A well-constructed fruit room will retain an equable temperature without much attention, but the ventilators should be opened a little on all favourable occasions, closing them on cold nights. Should premature shrivelling cause trouble, it is generally due to an excessively dry atmosphere, and the floor should be sprayed to create moist conditions. Amongst varieties of Apples for present use may be mentioned King of Tompkin's County, which is still in good condition, and a general favourite with those who like a soft Apple; Lord Burghley has also soft flesh and is highly aromatic, while Belle de Boskoop is a worthy successor in supplies to Blenheim Pippin for both dessert and culinary purposes. Ribston Pippin is at the end of its season, but when well-preserved it is still one of our best mid-season varieties, with crisp flesh of remarkably high flavour. Braddick's Nonpariel is a delicious fruit with firm flesh and highly aromatic. May Queen, a medium-sized fruit with crisp flesh is juicy and of excellent flavour; Norman's Pippin has mellow flesh and very fine flavour; Fearn's Pippin is a good variety, the flesh of which keeps firm to the last, and that very old variety Court Pendú Plat has also firm flesh of a high flavour. Annie Elizabeth and Bramley's Seedling provide the main supplies for culinary purposes, and both are in excellent condition. Pears in store require careful attention at this season, and the flavour of most varieties is enhanced if they are subjected to a somewhat higher temperature than the fruit room affords for a period of ten or fourteen days before complete ripening. Beurré Rance has melting flesh and a rich, vinous flavour, and Glou Morceau has a rich sugary flavour, but probably Joséphine de Malines is the best of all late Pears, for when perfectly ripe, its flesh is mellow and juicy and of delicious flavour.

Late Grapes.—Any Grapes still hanging on the vines should all be cut forthwith so that the vines may be pruned and put in order for another season. The Grapes should be cut with sufficient length of stem for the latter to be placed in bottles containing soft water with a few pieces of charcoal to keep the contents sweet. Where a Grape room is not available the Grapes will keep for some time in a dry, airy room, but they should be examined frequently for decayed berries.

THE FLOWER GARDEN.

By F. C. Puddle, Gardener to Lord Aberconway, Bodnant, Taly-Cafn, North Wales.

Herbaceous Borders.—Many herbaceous plants are showing signs of growth, and when the ground is in fit condition, borders from which the plants have been lifted and subsequently trenched, should be replanted. Well arranged herbaceous borders are amongst the most attractive of garden features, but considerable care is necessary to secure both a pleasing arrangement of the plants and a tasteful blending of colours. Most large gardens have at least three or four hardy flower borders, and the best effect is produced by blending two or three colours in each, so that they have an individuality of their own. The plants should also be selected with the object of making the borders attractive over as long a period as possible, and for this reason the colours should be given a wide interpretation. A blue border composed only of flowers which are actually blue, would have a very short season of attractiveness, but a most effective border lasting in beauty from June till October may be made by including all flowers pertaining to blue. Delphiniums, Lupins, Canpanulas, Asters, Iris, Aconitums, Erigerons, Phloxes of lavender and violet shades, Pentstemons and Gladioli may all find a place in the border, whilst Nepeta Mussinii make an appropriate edging. Even with this wide selection, it is possible that the border may appear a little dull during September, and a few clumps of Lilium Henryi and the yellow varieties of Montbretia, planted at intervals, will not only brighten the border at that season, but renew its interest by the introduction of another colour. If a warmer colour is preferred, Lilium tigrinum and the deeper shades of Montbretias may be used.

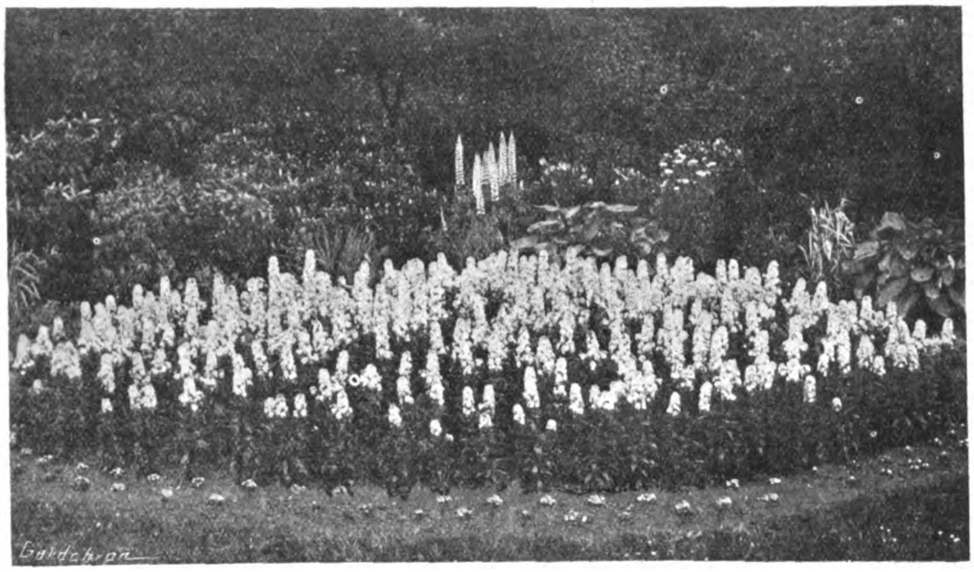

FIG. 55.—BED OF DOUBLE PURPLE HESPERIS AT ALEXANDRA PARK, GLASGOW.

(see p. 116.)

Climbers and Wall Shrubs.—Any necessary pruning of these should be completed forthwith. Clematis of the Jackmanii, Viticella and lanuginosa sections may be pruned back to the old wood, but those of the montana group are better pruned after flowering; if, however, this has not been done, weak and superfluous growths may be cut out now. The various species of Vitis should have their leading growths shortened and the side shoots cut back to two or three buds, so that a system of spurs is formed at fairly regular intervals on the permanent stems. Tender shrubs which are given the protection of a wall may also require a little judicious thinning, after which any fastening of the shoots which may be required should be done. Remove old ties which have become tight and likely to injure the bark. Shrubs which are not of climbing habit should not be tied rigidly in position, but so far as possible allowed to develop their natural shapes, provided the main stems have the protection of the wall.

FOR NORTHERN GARDENERS.

By A. T. Harrison, Gardener to the Marquis of Ailsa, Culzean Castle, Maybole, Ayrshire.

Repotting of Stove Plants.—The occupants of the stove are mostly rapid growers, and some of the plants may become too large to be of service; this applies to Codiaeums, Dracaenas, etc. To obtain shapely specimens ringing should be resorted to. Cut the stem half through, place a small piece of wood in the cut to keep the incision open, and then bind damp moss around the stem at this part. All plants treated in this manner should be arranged at one end of the stove for convenience in syringing them at frequent intervals with tepid water, thus ensuring that the moss is kept moist, and every encouragement given the plants to develop roots. Plants which have filled their pots with roots and are otherwise doing well should be shifted into larger receptacles, using a compost composed principally of good, turfy loam, to which may be added, as the requirements of the plants under treatment necessitates, peat or good leaf-mould, with sufficient sharp sand to render the compost porous. Cuttings of Panicum variegatum, Pilea microphylla and others of a like nature used for the edges of the stages, if rooted now soon form useful plants, and allow the older, worn out plants to be dispensed with.

Shallots and Onion Sets.—These vegetables are both largely grown and are very reliable crops with us, more so than Onions sown out-of-doors during March. They may both be planted whenever the soil is in a working condition, and when the ground has been loosened the sets need simply pressing into the soil about six inches apart in the rows, which should be twelve inches asunder. Examine the rows occasionally for the first week or two to replace any bulbs that may have been disturbed, as this frequently occurs before their roots have taken a firm hold of the soil.

Dahlias and Begonias.—The roots of Dahlias and Begonias should now be placed in a temperature of 50° to 55° and thoroughly moistened. Dahlias, particularly those of the dwarf Coltness Gem type, are increasingly popular, and are easily propagated from cuttings taken when the new growths are from three to four inches long. These, if rooted during March and potted on, make splendid specimens for filling beds or borders in June, and they make a grand display until frosts occur. The older stools also make quite useful plants, but the flowers of young stock are always superior. Begonias are not so readily increased from old stock; in their case it is advisable to sow a pan or two of different varieties each season, and grow the plants on. Procure seed of the very best strains, as the cultivation of choice plants entails no more labour than inferior ones, and the initial cost of the seed is very little more. If bulbils of Begonia gracilis (Martiana) were gathered last autumn, these should be planted now, as they take a considerable time to become established. This Begonia also forms useful additions to the borders in autumn, and is certainly worth growing. Begonias of the semperflorens type are also increasing in favour, and may be raised from seeds or by means of cuttings from stock plants, inserted in a warm house.

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM DEBILE.

THIS quaint species (Fig. 54) is a native of China and Japan and was named by Reichenbach in 1874 from an old figure which appeared in *Somoku Zuseta*—an old Japanese work—under the name of Calypso borealis. Curiously enough, five years later, Franchet and Savatier named it C. cardiophyllum, basing their description on a specimen collected by Savatier in the province of Nippon; they cited the figure quoted above, and also an earlier one which appeared, without name, in *Honzo Zufu*—a Japanese work published in 1828. C. debile is not a handsome species, but one of great interest to those who find delight in what are termed "botanical Orchids." It was figured in *The Gardeners' Chronicle* in 1905 (vol. XXXVIII, p. 442), the figure being a reduced reproduction of the original drawing referred to by Reichenbach, a copy of which was supplied by Messrs. L. Boehmer and Co., of Yokohama. The Yokohama Nursery Co. gave a coloured figure of C. debile in their catalogue for the year 1895.

C. debile is a terrestrial Orchid, and although more or less hardy in favoured localities, it is best grown in a cold frame in a shallow pan in a mixture of leaf-mould and chopped Sphagnum moss. Owing to its slender habit and the way in which the flowers hang down from the two-leaved stems, the plant is liable to suffer from winds and storms, therefore the protection suggested is desirable. The modern unheated alpine house would also serve for the protection of flowering specimens of this alpine species which Mr. E. H. Wilson collected in Szechuan at an altitude of 7,000 feet, where it was also found previously by Pére Farges. The flowers are small, the sepals and petals are pale green, each with a brown blotch at the base; the inflated white lip has purple markings at the mouth.

CYPRIPEDIUMS.

THE recent imposing exhibitions of these winter-flowering Orchids, both in London and Manchester, not only prove their great popularity but also the vast improvement made in the size, shape and colour of the flowers of these most useful plants during recent years.

In the environment of large cities and smoky districts, few plants can compare with Cypripediums to furnish a display of blooms during the darkest days of winter.

When Dr. Harris first suggested to Dominy the feasibility of hybridising and raising Orchids from seeds, little did either realise the results that would follow the cross-breeding of these plants. Could the original hybrids be brought together and placed besides the best novelties of the present day the differences would be surprising. To many, extreme size is a great attraction, and when large size is combined with refinement the result is a beautiful flower; but many extremely large flowers, even amongst Orchids, are inclined to be coarse, and have not the charming character of many that are smaller and more refined.

The largest-flowered Cypripediums do not produce inflorescences so freely as the smaller ones, hence they are not adapted to the production of flowers in quantity.

Some of the largest-flowered Cypripediums, perfect in shape and size, were shown by Mr. G. F. Moore on January 12, of which a detailed account was given in *The Gardeners' Chronicle* of January 16.

Some splendidly-coloured Cypripediums are in existence, and by carefully breeding with these the standard of the plants could be raised still higher.

A few which suggest themselves as being useful parents are C. Cappa Magna in its best varieties, C. Perseus, C. Cardinal Mercier, C. Marmion Holford's var., C. Christmas Cheer, and C. Kentigern, although the last is wanting somewhat in shape, yet the blooms have much latent colour which might be imparted to its progeny when the other parent is selected for its fine shape.

There are several others besides those mentioned, namely, the many beautiful C. Niobe hybrids, which may still be a factor in imparting rich colours to hybrids with larger and bolder flowers.

Cypripediums of the largest size and best shape do not always produce the best offspring, and if the ancestry of many of the choicest present-day hybrids is carefully traced, it will be found that many of them have as one parent a plant of quite a second-rate nature. C. Christopher is an illustration, and this also applies to many others, hence hybridisers of these plants should carefully study the ancestry of the plants they propose to use as parents. *J. T. B.*

CYPRIPEDIUM JEAN DOBRÉE FOX.

A FLOWER of a very pretty novelty raised in his gardens between Cypripedium Mrs. Spender Clay (Actaeus × Fairrieanum) and C. Actaeus, Drewitt's variety (insigne × Leeanum) is sent by Frederick J. Hanbury, Esq., Brockhurst, East Grinstead. In point of beauty it ranks with the charming C. Actaeus var. Bianca, raised by Sir George Holtord, but the C. Fairrieanum in C. Mrs. Spender Clay shows in the extended and undulated petals. The flower sent has a flat and well-rounded dorsal sepal, of cowslip-yellow colour, with some obscure emerald-green marking, the upper third and margin being pure white. The petals are cowslip-yellow with faint emerald-green lines and the lip is similarly coloured. The staminode is lighter in colour than the lip and bears an orange-coloured tubercle in the centre.

AGAVES.

AGAVE is an extensive genus of the Amaryllidaceae containing many noble and majestic plants as well as some smaller and elegant ones. They are characterised by thick, fleshy, spiny-toothed leaves, arranged in a rosulate manner, destitute of a stem in most instances, although in some species becoming caulescent.

For practical purposes the genus may be divided into two sections, one having a tall, ramose flower-scape attaining a height of from twenty to thirty feet, the other throwing a simple scape only, with the flowers usually densely crowded upon it, especially towards the terminal end, leaving the base clothed only with a few bracts.

The first section is represented by A. americana the American Aloe, as it is popularly but erronously called, and in which the spike is produced from the centre of the leaves and forms the terminal bud, whilst A. densiflora may be taken as a type of the latter section in which the simple scape is not always terminal, although it sometimes appears so. In many instances it is lateral, and, being developed near the top, it so pushes the centre of the plant over as to appear central, and the crown of the plant appears like a lateral.

Agaves are extremely long-lived plants and, as a consequence, comparatively slow growing, the popular idea being that they flower only once in a hundred years. This is true in a sense with the group producing ramose flower-scapes, for the fact of flowering brings death to the plant from exhaustion. It should be distinctly understood, however, that they do not require a hundred years to reach maturity, but in some instances they have been known to remain a century under cultivation without showing any disposition to flower. Those in the section which produces simple scapes are much freer in flowering and do not become exhausted through the production of flowers.

The plants comprising the genus are chiefly natives of Mexico and a few other parts of South America. A. americana appears to have been introduced to Spain about the middle of the sixteenth century, according to the accounts of old writers, but I can find no record of its introduction to this country until nearly a hundred years later. It would appear that other species were also introduced at about this period, but all under the name of "American Aloes," and several records are in existence of their flowering in this country. In the year 1729, a Mr. Cowell, who then had a famous garden at Hoxton, flowered a specimen of A. americana which he asserted was the first time it had flowered in England, and that those previously mentioned by various writers were not A. americana but other species which had been introduced under the same name. From this date down to the present time many plants have flowered in English and continental gardens, producing spikes from twenty to forty feet in height, and bearing, in some cases, several thousand flowers. The flowering of these plants is, however, a comparative rarity, and the announcement of such an occurrence is sure to attract attention. The giant spike, with its candelabra-like branches, never fails to excite the wonder and astonishment of all who behold it.

Various species of Agave are largely cultivated in Mexico for economic purposes. They are frequently used to form hedges, and when one considers the immense leaves and sharp spines of several of the species, one can readily imagine what a formidable front such a fence would present to any intruder. The leaves of some of the species also yield an immense quantity of fibre of a great strength, which is extensively used for rope-making in Mexico, and although not exported in any quantity, it has been used in this country in the manufacture of brushes. The sap is saponaceous and yields a substance which possesses the property of making a lather either with fresh or salt water. A favourite drink of the Mexicans is also obtained from the fermented juice of some species which is called "pulque." It seems to have been a beverage well-known to the inhabitants from a very remote time, for it was found to be a common drink in the country when the Spaniards first visited Mexico, and it would appear to have been indulged in to excess, for King Nezahualcoyotl issued stringent orders forbidding its sale, on punishment of death, to any but soldiers on the march, aged and feeble people and the mothers of babes in arms.

In considering the merits of Agaves as decorative plants one can advance arguments to claim the attention of gardeners in favour of their cultivation to a greater extent than is generally practised. They are remarkable for the beauty of their leaves, and yield a contrast afforded by no other genus. The larger-growing species are massive, noble plants and amongst the finest objects for surmounting flights of steps to terrace gardens, and for placing in vases on terraces during the summer, while the same plants when removed from their summer quarters form interesting objects for the winter decoration of the conservatory.

Some of the gems of the genus are neat, compact-growing plants, suitable for rustic nooks in many parts of the pleasure ground, and for plunging in rock-work. They may be grown by amateurs having no glass-house, for they are much hardier than is usually supposed, and any shed or out-house will suffice for their accommodation provided they are kept quite dry, and finally they should be favourites with amateurs who have limited space for the accommodation of plants and limited time for attending to them, on account of their great forbearance.

Although the plants are so accommodating that they may be left for a week without water in the height of summer without any visible injury having been caused, this is not the method to develop their greatest beauty and to attain the highest degree of excellence in their cultivation. During the summer they should be given a position under the full influence of solar light and have abundant supplies of water. The soil these plants thrive best in is a good turfy loam, rendered porous by the addition of a liberal portion of coarse sand, and the drainage should be perfect. Care should be taken when repotting the plants as the large. fleshy roots are easily injured, and this work should be done in the spring so that the receptacles are filled with roots before it is necessary to store them for the winter. *A. P. C.*

ALPINE GARDEN.

CROCUS HYEMALIS.

Winter-flowering Crocuses have had a sorrowful time this season, and the weather we have experienced has once more demonstrated the fact that we cannot hope to enjoy these exquisite little flowers to the full without giving them some form of protection against the vicissitudes of our winters.

Those who are possessed of an alpine house or a low structure which can be adapted as such, are fortunate, for in them may be grown the many charming alpines which come too early for the vagaries of our climate at this season. Those who have not a glass structure of this kind may utilise a frame for the purpose, although that does not give the pleasure derived from a house, where the flowers can be viewed at will and without any discomfort from the weather. A hand-light or bell-glass, may also serve and I have found that little boxes, all glass, with the exception of the wooden framework, are valuable for protecting such flowers as Crocus hyemalis, which has white flowers with faint streakings of purple on the outside, and flushed yellow on the throat.

The plant flowers variously from November to January and even February in seasons like this, but when exposed to the weather, it is seldom that the flowers open to the few faint rays of the sun at this season. The little, cone-like buds peep up from the ground waiting for the sun to induce them to expand, and too often the fragile, unopened flowers become sodden pulp. It is seldom, indeed, that our winters are suited to Crocus hyemalis, which seems to miss the sunshine of its native Palestine and Syria. *S. Arnott.*

TREES AND SHRUBS.

CORREA ALBA.

The subject of this note is one of the most perpetually-flowering plants we have, and unlike our native Gorse, which is said to be " in flower every month that has a ' R ' in it," I fancy it would be difficult to name any month in which flowers cannot be seen on Correa virens. [C. alba, Eds.]. Although the flowers are not very showy, the mere fact that this native of New South Wales thrives and flowers in our western districts should be sufficient to warrant it a ready welcome where it has not yet been tried.

The foliage is neat, from half-an-inch to one inch long, dark green and glossy above, while the undersides are covered with a light brown tomentum, as are the younger shoots. The greenish, tubular flowers are produced from the axils of the leaves, sometimes singly, and in many cases in twos and threes, but even when three flower buds are showing they are all at different stages of development, thus ensuring a succession of flowers.

This Correa (Fig. 56) is a comparatively rapid grower, and does well against a wall, where it may easily cover, in time, a space of twelve feet; it also does well in partial shade, and for sunny districts I would recommend it to be planted where it does not receive the full glare of the mid-day sun, and where it will never suffer from lack of moisture. From the remarks of various experts, I am led to believe that this is not a commonly grown plant, and I enclose a few shoots showing flower and foliage for inspection. *A. T. Harrison, Culzean Castle Gardens.*

When specimen hard-wooded greenhouse plants were in the hey-day of their popularity much more attention was given to the cultivation of Correas than is the case to-day. No doubt because of their drooping tubular flowers they are sometimes called Australian Fuchsias. Correas certainly comprise a very distinct and decorative family of hard-wooded plants, all natives of Australia. Most of those in cultivation are varieties or hybrids of three species, C. alba, C. cardinalis and C. speciosa. Six of the most distinct are Backhousiana, bicolor, Harrisii, magnifica, pulchella and ventricosa.

Correas thrive best in a peaty compost with a little fibrous sandy loam and plenty of coarse sand added. The usual method of increase is by cuttings, but some of the varieties and hybrids of C. cardinalis are not robust in habit and thrive better when grafted on a strong-growing form of C. alba.

During the winter give the plants cool greenhouse culture with a minimum night temperature of about 45°, or a degree or two cooler on very cold nights. In summer, stand the plants outside, selecting a position sheltered from rough winds.

The plant illustrated (Fig. 56) depicts one of the numerous forms of C. alba obtained by raising seedlings. This method of propagation is worth following up, for if seeds are obtained by cross-pollinating some of the best named sorts the majority will be more robust than the plants propagated by cuttings. *A. Osborne, Kew.*

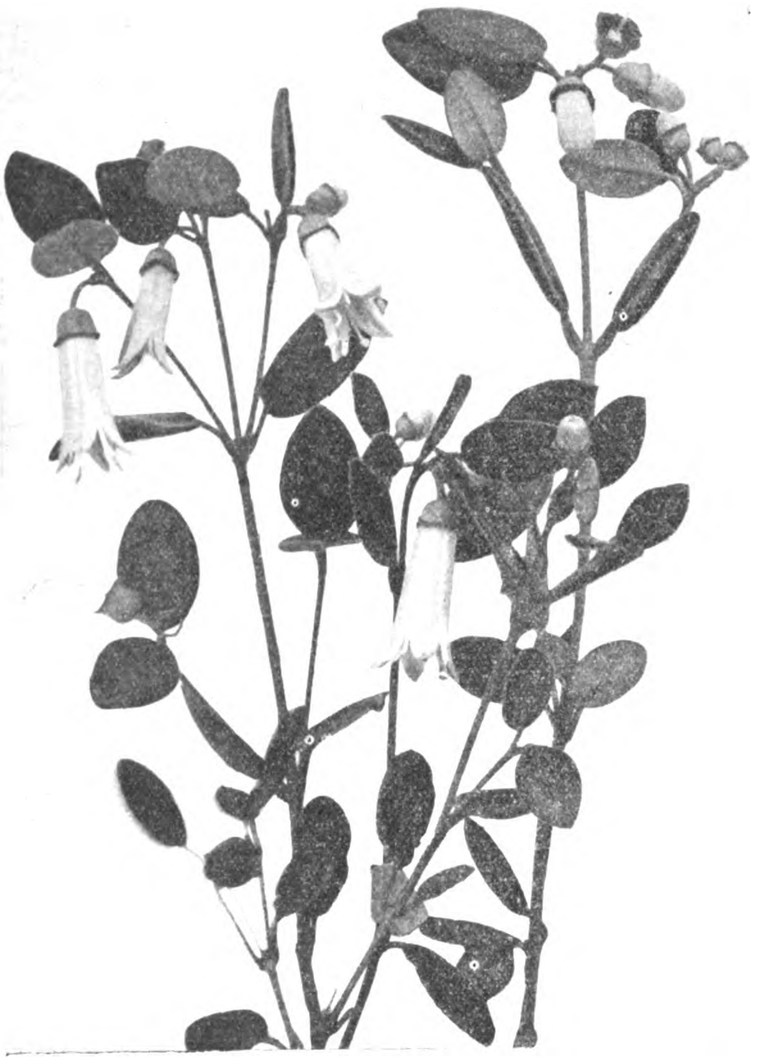

FIG. 56.—CORREA ALBA.

RIBES SPECIOSUM.

This is sometimes called the Fuchsia-flowered Gooseberry, and no doubt there is a slight resemblance in the manner the long red stamens protrude through the tubular calyx, these recalling Fuchsia gracilis very much to mind; but the prickles with which it is armed dispel all doubts, and prove its relationship to our more familiar Gooseberry.

Ribes speciosum is a deciduous shrub, but so impatient is it, that in some seasons, even by the month of November, it is again putting forth its delicate-looking, pale green leafage, and delicate as the leaves may appear, they do not seem to be adversely affected by the winter storms, but come safely through our most buffetting gales without any apparent injury, until, by February, the plant is in full leaf.

The flowers are produced freely along the undersides of the young pendulous shoots, and being of a bright red, almost scarlet, colour, they make a fine show during April and May, especially when the plants are allowed to grow more or less naturally. Trained on a wall Ribes speciosum will reach a considerable height, and it may be that the height of the wall alone limits its ascent, because each succeeding year's growth adds to its stature. Pruning, which should be performed so soon as the flowers are over, consists merely in removing the older wood, and thus encouraging the production of young, vigorous shoots, which, when the time of flowering again comes round, will be covered with their rows of scarlet flowers. The fruit is described by one authority as being " sweet and glittering, like amber beads," and " delicious in September," but I heartily agree with another authority, Mr. W. J. Bean, when he states, " the fruit is rarely seen in this country." I have not seen one fruit on our half-dozen or more bushes over a fairly long period. Perhaps coming from California it may require either some particular insect to pollinate the flowers, or stronger sunshine to enable its pollen dust to dry sufficiently to be potent. *A. T. H., Ayrshire.*

HARDY FLOWER BORDER.

DOUBLE HESPERIS.

I enclose photographs of beds of Hesperis matronalis, fl. pl., as we used to grow it here. At one time we grew three varieties, the purple as shown in the illustration (Fig. 55) and two white varieties. Of the white sorts one was tall growing, with woolly foliage and a loose flower-spike slightly tinted with colour at first but turning to pure white when fully open. The other white form was dwarfer in the spike, pure white, and had darker, glossy foliage.

We were very successful with these plants for years. They were bedded out early in spring and were quite a feature here. The critical time was when they were lifted to make room for the summer bedding, a shift they did not like; they were replanted in nursery beds until autumn when they were lifted, divided and wintered in cold frames. For some reason difficult to understand our plants lost their wonted vigour, decline set in, and ultimately we lost our whole stock.

I have been able, recently, to procure one of the white varieties from a southern nurseryman through *The Gardeners' Chronicle*, but I have failed so far to obtain the other two. The double Hesperis was comparatively common in the west of Scotland for a long period, but no one now appears to have either of the varietes mentioned. At its best here the double Hesperis equalled double Stocks, and during the evening the fragrance from these was almost overpowering. Perchance the varieties are to be found, but I do not know where. *Jas. Brown, Curator, Alexandra Park, Glasgow.*

THE "CUT FLOWER" VALUE OF DELPHINIUMS.

Few topics stand less in need of discussion to-day than that of the grandeur of the modern Delphinium as a garden plant; its popularity is universal and its merits are recognised by all. One feels less assurance regarding due recognition of the "cut flower" value of its noble spikes, and is rather disposed to the opinion that Delphinium flowers are not invariably appraised at their true worth.

Perhaps another way of putting it would be to say the flowers are not always used in a manner calculated to reveal the best that is in them, but the vital point is that the production of the correct material is a governing factor without which ideal results are impossible of achievement. It is an unfortunate misconception which supposes that the small, weakly spikes, side shoots, and more or less starved or stunted produce of Delphiniums should be the material used for cut flower decoration; no flower can give pleasure or win lasting approval which is constantly seen in an inferior, half-developed state, and to suggest that the larger spikes which reveal the true character and nobility of Delphiniums are too big and heavy for cut flower decorations savours of a very limited outlook regarding floral art. Feathery lightness and daintiness has each its legitimate purpose, and we have no lack of appropriate flowers for such purposes, but the bold, the impressive, the massive, even, are equally purposeful, essential and admirable, and it is under circumstances that warrant bold, imposing and striking effects that Delphiniums become immensely serviceable material.

Two important points may be mentioned at the outset, for they have been proved, not once or twice by uncertain chance, but by long and careful observation, and are furthermore endorsed by a commercial grower who cuts thousands of Delphiniums for a high-class trade every season.

First, the early spikes of the larger kinds are of smallest value, for the simple reason that they shed their centre petals and lower sepals very quickly if it should happen—as it often does—to be hot and dry just at the time they are sufficiently developed for cutting. The second crop of bloom which usually comes after heavy midsummer rains proves to be of greatest utility for providing cut flowers.

The second point is that all the largest, boldest-spiked varieties produce the best material for cutting if the roots are lifted and divided annually. It may be necessary to point out that the word "divided" is used, for I am not advocating the method of propagating from single crowns or cuttings, as is quite properly adopted by growers for exhibition. It would be rather extravagant to limit one's plants to single stems when growing for the express purpose of cutting, but by dividing a clump into portions carrying a few strong eyes, flower-spikes of good form and quality, without coarseness, are produced, and, strange as it may appear, it is an established fact that there are less of extra stout, timbery stems from the plants which are annually divided than from those which remain undisturbed for a second or third season. Let it be clearly understood that these remarks apply to the tall, strong, heavy-spiked varieties; not to the Belladonna type. Whilst the large, dense spikes are of great utility, more especially the later or second spikes, it must be admitted that the Belladonna type is even more serviceable, and it is greatly to their advantage that the flowers are possessed of greater staying power during the early summer and in periods of high temperature.

The variety Persimmon is one of the very best of all for cutting; it blooms early; even in the northern midlands it is a June flower; it produces an abundance of bloom of a very delightful colour, and it is of exceptionally hardy constitution. By affording varying treatment to different batches of Persimmon it is possible to maintain successional supplies of bloom from June right through to October. One batch should be left undisturbed for three seasons. This will give the earliest crop, and by cutting over the plants after flowering a good second crop will be secured. One batch may be lifted and divided shortly after the flowers are cut; another batch may be divided in early spring, another when spring is rather far advanced, and by working these different batches intelligently they will follow each other into bloom, and all but the late spring divisions will yield two good crops. It is by no means every variety of even the Belladonna type which will justify all these assertions, but Persimmon has still another very valuable point to its credit—it resists mildew even to the very late autumn. The blemish of mildew is bad enough in the garden, but is intolerable in vases and baskets, and, unfortunately, some otherwise excellent varieties are faulty on this score. Belladonna itself is frequently rendered unusable, while Persimmon, growing close by, remains perfectly clean. Mildew often spoils the second crop of Rev. E. Lascelles, and if the weather is very hot and dry during the period of the first crop the flowers lose their white centres, but a good spike of Rev. E. Lascelles variety is so beautiful and the plants flower so freely that there should be no hesitation in soaking and mulching the roots for the early crop, and in spraying with potassium sulphide just as the spikes of the late crop begin to rise. Only two reasons need be given when this spray fails to arrest mildew; either careless preparation and application is the cause or spraying is delayed until the fungus is too far advanced. Nevertheless, it is of great advantage to have varieties of Delphiniums which even in the damp autumn keep free from mildew, and Blue Bird, exceptionally good for cutting, both early and late, never seems to mildew, whilst similar compliments may be paid to the varieties Mrs. H. Kaye and Edwin Beckett.

It would be imprudent to pretend to give a list of varieties suitable for cutting; many good ones would undoubtedly be omitted, and some would be included which would be satisfactory to some and disappointing to others, but in a very large collection the three or four which have been named are so conspicuously and consistently good that I feel fully confident that they cannot fail to please.

Cut flower production is of considerable importance to gardeners in large establishments where much entertaining is done, and Delphiniums are decidedly worthy of careful consideration in this connection. *A. J. Macself.*

MESEMBRYANTHEMUM.

LITHOPS.

(Continued from p. 102).

Dr. Marloth informs me that L. Marlothii "is a marvel of mimicry; it grows in shallow depressions of granite filled with detritus of the reddish rock and looks exactly like its surroundings. I have put my hand on some of them without knowing they were there until I investigated the spot more closely. There was no other plant visible!"

As the place where it grows has been visited by many collectors and the plant has not been previously discovered, it is evidently well concealed by its imitation of the soil in which it grows. This imitation of the soil is very great; for Dr. Marloth has sent me a small sample of it, which consists of grit only, most of the particles being of about the size of the letter "o" used in printing this, mingled with larger pieces up to the size of small Peas, and coloured white, creamy, yellowish, reddish and brown. These colours and the granular structure correspond very closely with the colours of the irregular and pimply surface of the plant after the growing period is over, but when making fresh growth, the glittering, bright green pimples and elevated creamy markings might cause it to be more conspicuous. This gritty soil can hold but very little moisture, and being contained in but shallow depressions of solid rock there can be no vapour arising from the subsoil. Therefore, as the annual rainfall is very small and long droughts occur, it would seem probable that the plant exists on moisture condensed by the rock when it cools down at night.

Under cultivation I expect this plant will attain to much larger dimensions than those above given, and will probably be found to be liable to damp off if given too much water.

L. marmorata, N. E. Br., in *The Gardeners' Chronicle*, 1922, vol. LXXI, p. 80. To this add reference:—Karsten in *Onze Tuinen*, August, 1924, p. 78, with fig.

L. pseudotruncatella, N. E. Br., in *The Gardeners' Chronicle*, 1922, vol. LXXII, p. 65, f. 33. Add reference:—Mesembryanthemum pseudo-truncatellum, Schwantes in *Monatssch. f. Kakt.*, August, 1920, p. 117, with figs.

L. rubra, N. E. Br.—Said to resemble L. optica, but differs from that species by its intense purplish colour, which it retains throughout the winter, and by its seeds being of a darker brownish red.

Mesembryanthemum opticum var. rubrum, Tischer in *Zeitschr. f. Sukk.*, vol. II, p. 65 (June, 1925).

South-west Africa: Locality and collector unknown.

The above is all the description given of this plant. I have not seen it, but from the characters mentioned, I have no doubt that it is quite distinct from L. optica, N. E. Br.

L. Ruschiana, N. E. Br.—Growths $\frac{3}{4}$–$1\frac{3}{4}$ inch long and 7–19 lines broad, obconic, with a transverse fissure $2\frac{1}{2}$–10 lines deep across the top; lobes convex on the top and somewhat elliptic in outline viewed from above, glabrous, with the sides frequently of a slightly amethyst colour, and the top varying from milky pearl-grey to a yellowish or reddish-ochre tint, marked with a few impressed pits and branching yellowish-red lines. Flowers small, $\frac{3}{4}$–1 inch in diameter, yellow. Capsule 5-celled. Seeds few, large.

Mesembryanthemum Ruschianum, Dinter in *Fedde Repert., Beihefte*, vol. XXIII, pp. 25 and 80 (1923); M. Ruschiorum, Dinter and Schwantes in *Zeitsch. f. Sukk.*, vol. II, p. 21, with fig., and M. Ruschii, Dinter and Schwantes on p. 22 (March, 1925).

Great Namaqualand: In the neighbourhood of Windhoek, near the Khan Coppermine, west, between Rossing and the old railway line, Rusch.

Mr. Dinter having published this under three different spellings of the specific name, I have adopted the earliest form of spelling, which was published two years prior to the other variants.

L. terricolor, N. E. Br., in *The Gardeners' Chronicle,* 1922, vol. LXXII, p. 65. The following completes the description of this plant, taken from living flowers and fruit. Calyx compressed, 3½–4½ lines broad, 5-lobed, glabrous purplish-green; lobes 4–5½ lines long, ovate, obtuse, with membranous edges. Corolla 10–13 lines in diameter, expanding in the afternoon, slightly scented; petals about 30, in 2 series, 4–6 lines long, ½–¾ line broad, linear, entire and obtuse at the apex, clear bright yellow. Stamens numerous, erect, collected into a cone, unequal, 2½–4½ lines long: filaments white, ciliate at the base; anthers pale yellow. Stigmas 5, overtopping the stamens, 3–5 lines long, light yellowish. Capsule 3–4½ lines in diameter, obconic, 2-edged at the lower part, flattish or slightly convex at the top, whitish, with 5 valves and cells, and when expanded 5–7 lines in diameter; valves 1–1½ line long and as much in breadth, triangular in outline, pallid; expanding-keels about as long as the valve, closely contiguous nearly to their tips, where they diverge and are furnished with broad, obtuse membranous, marginal wings; cells open, without cell-wings. Placentas on the floor of the cells. Seeds numerous in each cell, minute, about ¼ line long, subglobose, smooth, pallid, with a brownish nipple.

Laingsburg Division: Near Grootfontein, Frith! Willowmore Division: Near Miller, Frith!

L. Vallis Mariae, N. E. Br.—Growths ¾–1½ inch long and 7–23 lines broad, obconic, with a transverse fissure 1½ line or more deep across the top; lobes flattish or slightly convex on the top, half-elliptic or somewhat lunate in outline viewed from above, varying from nearly smooth to more or less rugose on the top from irregular and somewhat zig-zag impressed lines, entirely yellowish or bluish-milky-coloured with the sides purplish. Corolla 12–16 lines in diameter, yellow. Seeds ⅓ line long, white with a brown nipple.

Mesembryanthemum Vallis Mariae, Dinter and Schwantes in *Zeitschr. f. Sukk.,* vol. II, p. 22, with fig., March, 1925.

Great Namaqualand: Marianthal Farm, Beetz. *N. E. Brown.*

(To be continued.)

ROSE GARDEN.

ROSE ARIEL.

It is unfortunate that there are two Roses bearing the name of Ariel, although the one illustrated (Fig. 57), is not now very well known in gardens, whereas the brilliant-hued Ariel sent out by Messrs. Bees has already acquired popularity. It appears that the original Ariel was raised by Messrs. Paul and Son, of Cheshunt, many years ago, and probably is of the same parentage as Tea Rambler. There can be no doubt as to the beauty of Ariel as indicated in the illustration, which shows a specimen cultivated for many years by the Rev. F. Page-Roberts in his garden at Strathfieldsaye before he retired to Stratfield Sturgis. The veteran rosarian is five feet ten inches in height, therefore a good idea of the size of the weeping standard may be obtained by comparing the two. The original Ariel is a June-flowering Rose, and is in no sense perpetual, but it produces its large, single, pink blossoms abundantly. Mr. Page-Roberts informs us that the plant is pruned back hard each year directly after it has flowered, and it rarely fails to give a good account of itself. It would be interesting to learn whether other old friends of the late Mr. George Paul possess specimens of the Cheshunt Ariel, and if so, whether they are as successful with it as the Rev. Page-Roberts has been.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.

Urgent Communications.—*If sent by telegraph, these should be addressed "Gard. Chron.," Rand; or by telephone, to Gerrard, 1543.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

MR F. KINGDON WARD'S EIGHTH EXPEDITION IN ASIA.*

XXV.—WINTER.

THE following day, January 28, we reached Oga Dzong in two hours, after halting at a prettily situated monastery for a drink of hot yak milk. The valley here is full of villages and there is good pasture for large herds; just across the glen is a group of snow peaks, but they look very barren. As the transport was not ready, we had to cool our heels for the rest of the day at Oga, so we seized the opportunity that night to take an observation for latitude.

On the 29th we proceeded towards Tsetang by the main road, which soon diverged from our route in April to cross a spur and a valley, and then another spur, from the summit of which we saw the Tsangpo below us once more. Descending on a steep slant, we reached the left bank, and followed the river for a couple of hours, to a wretched hovel where we spent the night. Although it was comparatively warm in this trough (altitude about 10,500 feet) compared with the top of the plateau (average altitude about 15,000 feet) one immediately understood why the valley here is almost devoid of plant life, while the slopes a thousand feet higher up are quite thickly clad with scrub.

We found ourselves in a thick fog of flying grit; so dense was it, that though the Tsangpo here is at this season under half-a-mile wide, we could not see the opposite shore. The wind blew with horrible violence, and was bitterly cold; sometimes we could scarcely make any headway against it, and were blinded and choked as in a desert sand storm. No wonder it sucked the life out of the vegetation. For it must be remembered, this was no unlucky storm; the wind blows day after day for weeks, as regularly as clock-work, only ceasing for an occasional snow storm; and always it blows down the valley, so that we marched in its teeth. The nights were calm and clear, though thick with a red dust haze, through which the setting sun peered dimly, to be succeeded by a ruddy moon; only the stars right overhead shone brightly, and as they sank down in the west they were soon smothered and lost to view. By morning much of the dust had settled again, and the sky was a bright China blue, like enamel. But about eleven o'clock the wind sprang up and raged with increasing strength till sunset, when it ceased abruptly. The river, so placid at first, was soon flogged into waves, till the brash ice tinkled and clinked along the shore. The going over the dunes against this awful blast was very heavy, and in the course of a seven hours' march on the 30th, we only did about twelve miles, sleeping in a village a mile back from the river. I was by this time feeling very sorry for myself. The dust had penetrated under my goggles, through my clothes, and under my fur cap; it even seemed to penetrate through the pores of my skin, making me feel stony all over like a Saxifrage. Cawdor's plight was no better.

However, we were now quite close to Tsetang, On the 31st we continued a few miles up the left bank, crossed the river in a barge, and early in the afternoon reached Tsetang again, nearly ten months after leaving. It seemed warmer now than it had been in April, but that was because of the bright sunshine; the nights were cold now.

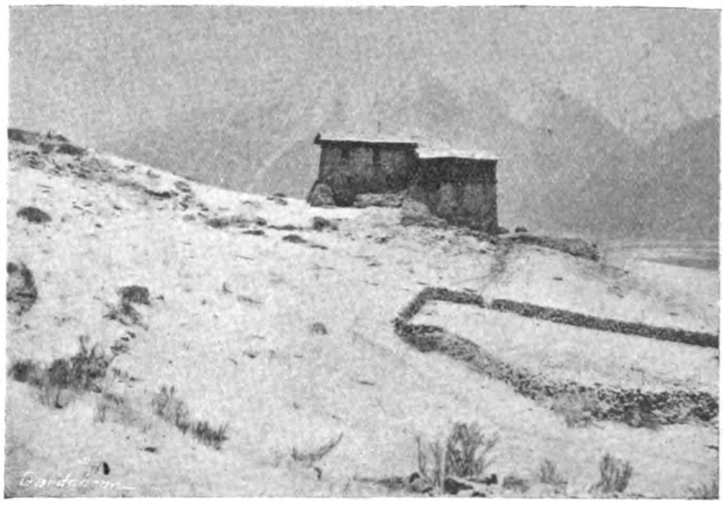

FIG. 58.—NEW YEAR'S DAY, 1925; THE NAMBU GOMPA WHERE CAPT. KINGDON WARD AND LORD CAWDOR SPENT THREE DAYS.

Our friends pressed us to rest a day in Tsetang, but we had no wish to stay an hour longer in Tibet than need be. Between us and India loomed the mighty snowclad ranges of the Trans-Himalaya and Himalaya, and we wanted to get over them as quickly as possible; it was no good sitting down in the sunshine of the Tsangpo valley and thinking about it. So on February 1 we were off again, marching up the stony valley towards the first pass. This valley is quite well populated, and in the villages were the usual clumps of Poplar and Willow, with Buddleia, Hippophaë, etc., by the stream. But these wide, flat valleys owe their formation almost entirely to the lack of trees on the hill-sides, which are deeply trenched by the heavy rainstorms, and pour vast quantities of gravel into the main valley, while the soil is instantly swept away, or blown away. Where there is forest, the glens are always narrow and V-shaped, if water-worn, U-shaped if ice-worn. Higher up the valley, however, as usual, there were plenty of dwarf shrubs, such as Ephedra, Caragana, Rhododendron, Potentilla fruticosa, and Lonicera spinosa, as well as herbaceous plants like Primula Waltonii, Isopyrum grandiflorum, Meconopsis horridula, etc. In fact, the northern flank of the Trans-Himalayan range really has quite a respectable flora, and it is bare only on the open plateau, where there is no water, and no protection from the wind.

On February 3, still travelling almost due south, we crossed the Trans-Himalayan range at over 16,000 feet, and found ourselves on the plateau once more; despite the altitude, there was very little snow here, but the wind was awful, and we lost the way and did not reach a house till 10.30 at night. The view on which we gazed next morning was a desolate one. The air was very still, and the cold intense; in every direction huge snow peaks towered up into the blue sky, but all around us the bare plateau, patched with snow, heaved and rolled like a frozen sea. Here and there were the black tents of herds whose faces were equally black, and numbers of yak nibbled at the short yellow turf in the hollows. After gaining the summit of a ridge we could plainly see, far away in the south, a mighty range of mountains glittering in the sunshine; it was the Himalaya. From the plateau we descended into an arid, dusty valley, thickly populated for Tibet, and crossed a small stream which was really one of the source streams of the unexplored Subansiri, a big river of Assam; and after a slight diversion to the east turned south again. We were following the ninety-second meridian pretty closely now. The tumbled hills here, between the great main ranges, were harsh in outline, lacking the flesh of vegetation to clothe the bare bones.

On February 6 we had to cross a high pass, so we started in good time, and rode ahead of the caravan in the hope of crossing the pass before the wind got up. However, we did not, and we came in for a particularly bad time on the other side; for as we approached the foot of the Himalaya the good weather broke up, and we came in for a series of snow storms, and here the snow lay fathoms deep, as at the Doshong La in October. The night of the 6th was one of the worst in our experience. Our quarters were cramped, miserable and draughty, and the dung fire gave out nothing but smoke. We had 50° of frost, and slept little; but the transport animals had to stand out in the yard all night in the snow, with their saddles on their backs! How they survived such an ordeal I do not know.

Following this bad night, the 7th saw the longest and most difficult march, in deep snow; but we were buoyed up by the thought that we were now crossing the main Himalayan range. The wind started early, and the ascent through the frozen, powdery snow to the summit of the pass was slow work. At every step we went in knee deep, and the toil on a steep slope may be imagined. The view from the top was not pleasant; nothing but snow in every direction, with rugged ranges of mountains all round, and slate-grey clouds frothing sulkily

---

* The previous articles by Mr. Kingdon Ward were published in our issues of April 12, May 17, June 21, August 9, August 30, September 27, November 1, 1924, April 4, May 9, June 6, June 20, July 4, July 18, August 1, August 15, September 5, September 19, October 10, October 24, November 21, December 5, December 19, 1925, January 2, and January 16, 1926.

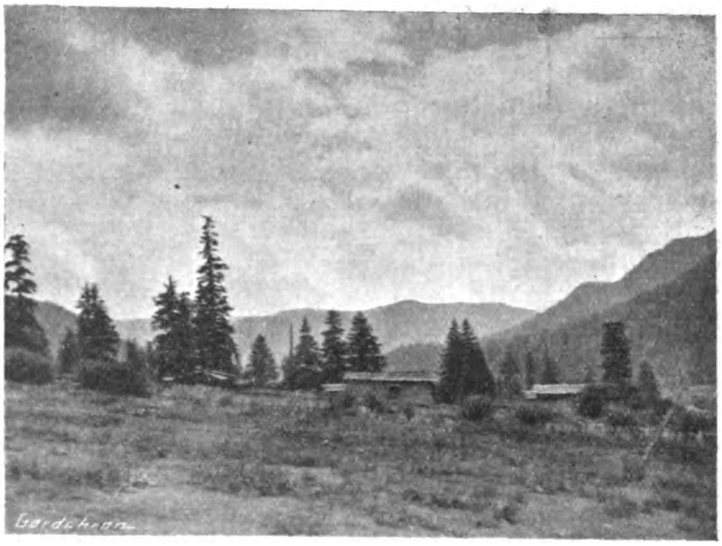

FIG. 59.—TUMBATSE; CAPT. KINGDON WARD'S BASE FOR FIVE MONTHS.

over them. If it was unpleasant in the Tsangpo valley with the wind hurling grit in one's face all the time, it was absolute torture now, when the grit was replaced by frozen snow. A blizzard of ice spicules met us at the top, and we floundered on knee deep, at the rate of a mile an hour, seeing no vestige of a house. At last we crossed a low col, and saw a deep valley right at our feet; a yak caravan (Fig. 61) was toiling up the slope, for the Tibetans prefer to travel at night, if there is a moon, thereby missing these gales. It is a wise plan for 40° or 50° of frost is nothing when you are marching, so long as the air is quite still.

We reached the large village of Tsöna at dusk, and were put up in a fine, big house, where they had wood fires, and we soon got warm drinking buttered tea. We felt elated for we were over the Himalaya, and that in seven days; by the Gyantse route it would have taken us at least fifteen.

We now thought ourselves practically in India; six or eight days we supposed at most separated us from the plains. We were quickly undeceived. In the first place we learnt to our disgust that we should have to stay in Tsöna the following day, as there was no transport ready; indeed, the people wanted us to stay two days, but we flatly refused. In the second place, the short road via Tawang was closed by snow, and we should have to go by a lower pass and a longer route. And in the third place it appeared that we should have to go through part of Bhutan, for which we had no passport, so that things might be made difficult for us. As the whole valley was, of course, under a deep mantle of snow, we stayed in the house on the 8th and I repacked things, wrote letters and looked at the seeds, wondering the while how they were standing the trip. So far, they had had to put up with temperatures so low as 15°F., but it would not be very long now before they would have to face 90° F. However, my thermos flasks were still intact, and, indeed, were quite sound when posted from Calcutta three weeks later.

We got off late on the morning of the 9th, with pony transport, a regiment of yak having been dispatched to try and stamp a trail over the Tawang Pass, by which communication with India is maintained; we, however, made for the Pö La, which is only 14,900 feet. The day was brilliantly fine, but we started so late that though it took us only three hours to reach the pass, by the time we got there the wind had risen, and the snow was flying once more. Little we cared. It was the last mountain range between us and India, and we panted up the steep slope, floundering in the snow, fairly bursting to see down the southern side of the Himalaya, after six weeks of winter on the plateau.

At last, we reached the summit, and there, far below us, we saw Fir trees, looking very Christmasy nevertheless. Down we went, by a rough path; but I went wandering off along the flank of the hill, because a few hundred feet below the summit the Rhododendrons began and I was able to gather seeds of several species.

The change was extraordinarily abrupt, and we had not gone far down the valley when we came into whole thickets of Rhododendrons, of much the same type as those met with further east. I noticed 'Anthropogon,' 'Triflorum,' 'Cinnabarinum,' 'Lacteum' and, lower down, masses of a small 'Arboreum,' with bronzed leaves; this species was new to me and I collected seeds. (K.W. 6403).

Towards evening we reached a Mönba village on the edge of the forest, high above the river, and halted for the night. There was a fair amount of snow here, but it was soft and woolly; next day we would be out of the snow for ever—or at any rate until we got back to England! *F. Kingdon Ward.*

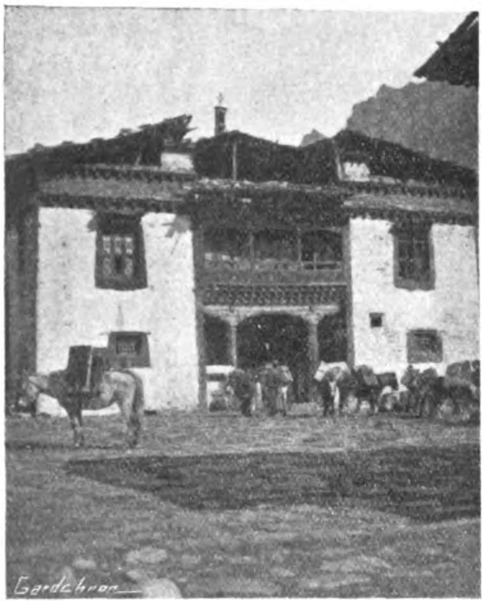

FIG. 60. AN EARLY MORNING START.

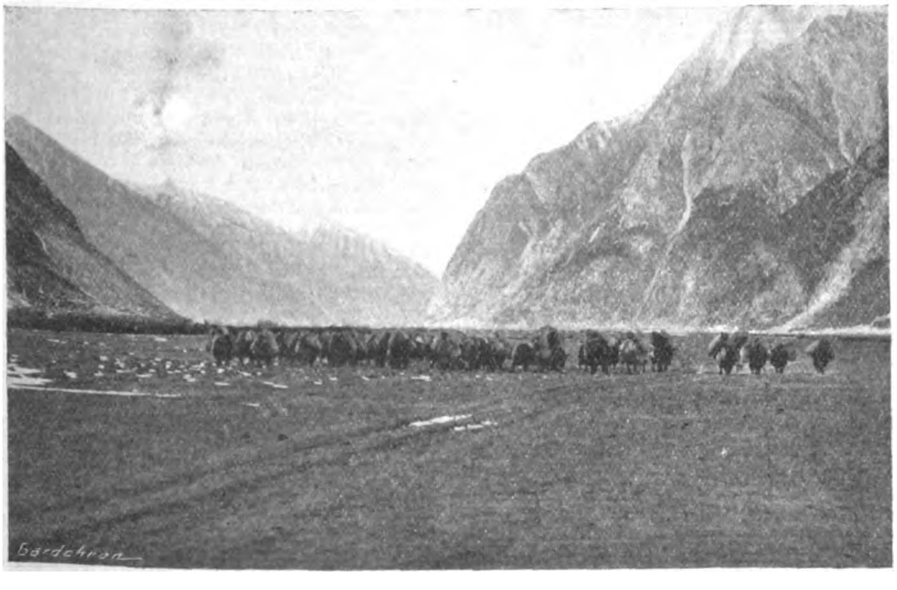

FIG. 61.—YAK CARAVAN ON THE PLATEAU OF TIBET.

THE MOTH-CATCHING ARAUJA SERICIFERA.

I GATHER from Mr. Smith's reply to my query, that the Potherb moth was the species he referred to as having been caught by the flowers of this Arauja sericifera; and if he cares to send me specimens of any other moths captured by this plant and unknown to him, I will let him know their names. The Privet Hawk and Silver-Y moths and Small White butterfly have been recorded as victims as well as bees, wasps and bluebottle-flies, but the Humming-bird Hawkmoth, although visiting the flowers, appeared able to withdraw its proboscis safely. A short account, illustrated, with a sketch of the flower and arrangement of the anthers by which the insects are caught, appeared in the *Gardeners' Chronicle* for Dec. 16, 1916, and this peculiarity is also referred to in *Revue Horticole* for Nov. 1, 1903 (p. 491). The subject has also been discussed in the *Bull. de la Soc. des Sciences Natur. de l'Ouest de la France*, for 1899; and in the *Journal d'Horticulture de France* for Feb., 1911, Mr. Künckel d'Herculais has a note on Arauja and Hedychium flavum as insect-trapping flowers. It may be well to add that Arauja sericifera was formerly known as Physianthus albens (White, or Brazilian Bladder Flower) and is more or less hardy outdoors in favourable localities in Britain, though usually grown inside. *C. Nicholson, 35, The Avenue, Hale End, London, E. 4.*

NOTICES OF BOOKS.

The Scent of Flowers.*

Into a neat little book, Mr. Hampton has collected a large amount of information concerning perfumes in nature, with special reference to flowers and plants.

The author, in preparing this volume had in view the fact that the results of the researches of chemists and perfumers in the pursuit of their trade are not easily accessible to the gardener, or to the general public. To satisfy such readers, Mr. Hampton has mentioned the sources whence he obtained much of his information, and the list of authorities, given at the end of each chapter, should be of inestimable value to every student of the subject.

The author begins by giving a description of the olfactory sense, and he states "The pleasure value of the sense of smell is usually underrated because we fail to realise that all that we call 'flavour' in food is an olfactory sensation." This is not altogether easy to understand when we recall the particularly evil odour given forth by Strawberries when a considerable number have been brought indoors. Were this perfume to intrude upon our taste the fruit would soon be banished from our tables.

To appreciate fully the composition of scent a certain knowledge of chemistry is necessary. The perfume of flowers is due to an essential oil known as an attar. This is compounded in general with carbon and hydrogen, oxygen, often nitrogen and in some cases sulphur. To these are added "esters," compounds of acid and alcohol. It is, for instance, to an alcohol of which geraniol is the principle, that is largely due the scent of Attar of Roses. The more delicious and delicate the scent of a blossom, the more complicated are the chemical components of its attar. The author tries to be as little technical as possible in his definitions of scent, but we wonder whether the "man in the street," for whom his book is intended, will be much wiser when he reads that "the Attar of Jasmine consists principally of *benzyl acetate* shaded off with traces of the allied *benzyl formate* and *benzyl propionate* and associated with *methyl anthranilate* and *indol*." Still, this is an extreme case, and there is so much to arouse the wish to learn more of the subject of the book that the scientific side of the composition of scents should be readily mastered with a little trouble.

In the treatment of so illusory a subject as scent, the writer has a hard task, owing to the fact that the sensitiveness of the olfactory organs is so varied in individuals. Thus, while some persons revel in the scent of Hawthorn, Phlox, or even Privet, others set them down as detestable. It is the same with the strength of perfumes. There are many folk who can detect no scent in Frau Karl Druschki Rose, while others describe minutely the delicate perfume given out by this Rose before the flowers are fully open.

To general readers the interesting, though brief, chapters devoted to the Function of Scent and to its History will be very attractive. As regards the first, there is no doubt but that insects are far more appreciative of scent than we are—witness the night-flying moths that discover the Phloxes and Œnotheras when all other clues than perfume seem to be at rest.

The book closes with several appendices, including a list of the component parts of the Orange, Bitter Orange, Gardenia and Lavender attars; a list of scented shrubs, perennials, annuals, bulbs and plants for hedges and walls of a small garden. A special appendix is devoted to the sweet-scented flowers of autumn. A rather fuller index would, in our opinion, have enhanced the value of the book.

* *The Scent of Flowers and Leaves, its Purpose and Relation to Man*, by F. A. Hampton, M.A., B.M., B.Ch. (Oxon.). London. Dulau and Company, Ltd., 34-36, Margaret Street, W. 1. Price 6s.

ORIGIN, EARLY HISTORY AND DEVELOPMENT OF THE POTATO.

(*Continued from page 85*).

Safford* has demonstrated that Heriot's "Openauk" was not a Solanum at all, but Glycine apios (Linn.) a tuber-bearing Legume. The tubers of Glycine apios were an important food of all the Indian tribes of eastern North America, from the Gulf of Mexico to the St. Lawrence river. By the English colonists they were called Indian Potatos, Big Potatos or Ground Nuts. The various Indian tribes had each its name for them :—"Openauk," "Openaug," "Penag," and "Penac," were their Algonquin names. The Ground Nut corresponds exactly with Heriot's description, and while there is no species of tuber-bearing Solanum indigenous to east North America, Glycine apios is still to be found in abundance throughout the woodlands of that district. The confusion between the "Openauk" of Virginia and the "Papas" of Peru, can be traced to Clusius, who, although not suggesting that they were identical, remarked that the tubers called "Papas," observed by Cieca, were apparently not unlike the roots which the Virginians called "Openauk." Clusius was referred to by Gerarde as though he were responsible for identifying the Peruvian "Papas" with the Virginian "Openauk."

It will be seen from the above how the presumption of a Virginian origin of the Potato has arisen. Authorities are agreed that the Potato is not indigenous to North America, and that if it did come from Virginia it must have been imported there in some way. Raleigh personally, had probably nothing to do with the introduction of the Potato, and he never visited Virginia, although he tried to do so and failed on his return from his expedition to Guiana in 1585.

A monument has been erected to the memory of Sir Francis Drake in Offenburg, Germany, with the inscription : "Introducer of the Potato into Europe in 1580." It is true that Sir Francis Drake encountered Potatos in November, 1578, as a food in use by the natives of South Chili, but it would appear that he did not consider them worthy of serious attention.† A menu card is still extant showing the fare at a banquet which Drake gave in November, 1580, to the honour of Queen Elizabeth on board his ship. In this menu no mention of Potatos is made.

It is not surprising that there is so much vagueness in literature concerning the introduction of the Potato into England ; the principal actors of the drama could have had no inkling of the great future in store for the plant. It is, however, possible to reconcile the above traditions in the following manner :—Potatos may have been brought to Virginia by Drake, having been plundered from the Spanish, or they may have been obtained by the colonists from the Spaniards who had also settled in the Southern States of North America,‡ or by English pirates who had pillaged Spanish ships. The Potatos could then have been brought to England in ships under Drake's command and by Raleigh's people, not, however, by Raleigh himself. This solution to the very difficult question concerning the introduction of the Potato into England is, when all matters have been duly considered, quite as probable if not more so, than any other of the suggestions submitted. Gerarde grew Potatos in his garden before 1597, and the return of the colonists in 1586 is a likely date for their arrival. Safford, however, after a critical study of the available evidence, comes to the conclusion that the introducer and exact date of introduction of the Potato into England cannot be determined.

The above does not exhaust by any means the stories concerning the entry of the Potato into this country. Putsche (1819) maintained that Sir John Hawkins introduced the Potato into Ireland in 1565,, having obtained it from Santa Fé de Bagota. Safford, however, points out that Hawkins never visited Santa Fé de Bagota, but called for provisions at a port called Santa Fé on the coast of what is now Venezuela, where he obtained, amongst other things, Sweet Potatos. Sir Joseph Banks also, in a lecture given to the Horticultural Society, London, in 1805, criticised the suggestion that Hawkins introduced the Potato, and stated that what the sailor did handle was the Sweet Potato. Another tradition has it that the first coming of the Potato to Britain was accidental, tubers having been washed ashore from a trading vessel returning from a transatlantic voyage and wrecked on the Galway coast. The first published description of the Potato was given by Bauhin in 1596. Bauhin was the first to give the Potato its present botanic name, Solanum tuberosum. Gerarde, in his *Herball*, (1597), was the next to depict it and in 1601, Clusius in his *Rariorum Plantarum Historia* described the plant, naming it "Papas Peruanorum."

So far, therefore, we can only state with certainty three facts, viz. :—(1) The plant is indigenous to South America ; (2) it was introduced into Europe in the latter part of the sixteenth century ; (3) two independent introductions took place, one into England and one into Spain. *T. P. McIntosh.*

MARKET FRUIT GARDEN.

As there were only eight days in January entirely without either rain or snow, all work except pruning was seriously hindered. The land was nearly always too wet or too hard with frost for either planting or digging, and winter spraying was frequently interrupted by wind, rain or frost. Thus there are heavy arrears of work to be overtaken. The total fall of rain and snow at my place amounted to 3·31 inches, making the fourth month in succession with over average rainfall, denoting a winter both wet and severe.

Winter Spraying.

I just failed in my intention to get all the Plums sprayed with tar distillate wash during January, but one more fine day would have seen the work completed, except for a few quite young trees. Fortunately the buds are backward, and no harm will be done ; and there should be ample opportunity during February to spray the Apples. It would be wiser another year, however, to be prepared to begin this spraying at the first favourable opportunity in December, and so make sure of getting the work finished while the buds are quite dormant. One should then be able to select only the most settled weather, and avoid having results upset by rain. The first plantation of Plums sprayed was finished under excellent conditions, except that on one day, when the wind rose at mid-day and stopped the work, several barrels of the mixed wash were left over and became frozen. The makers of this particular wash warn one against this, and evidently not without reason, as the frozen wash showed a little tendency to separate out from emulsion, and it did not seem to spread quite so well on the trees nor to burn the grass so much. I shall be interested to see whether there is any difference in the final results where the trees received the frozen wash. Perhaps it would have been wiser to throw it away : but it is expensive stuff. The spraying of a second plantation was attended by less fortunate conditions, rain falling on several occasions soon after work was finished for the day. Here again I kept a record, and shall be able to trace any effect on the cleansing of the trees and the control of insects. I had one case last year where rain followed immediately after spraying, but it did not appear to make any difference. Gardeners who have only a few trees to spray are fortunate in being able to choose perfect weather for the work.

I hope I have bought enough of this tar distillate wash to spray every Apple and Plum on the place. After what I have seen on several other fruit farms, in several seasons, and my own experience of last year, I have not the slightest doubt as to the great value of this treatment. It probably does all that can be done in the way of controlling aphides and Apple suckers, besides cleaning the bark perfectly. There is also the evidence of one experiment at Long Ashton that it is capable of preventing brown-rot of Plums. If it will really control this disease, as well as the dreaded leaf-curling aphis of Plums, it will indeed prove valuable for this crop. Several species of caterpillars, including winter moth, are also controlled to a considerable extent, though, in a bad year, a certain amount of spraying with arsenate of lead will no doubt be necessary in spring. There are many brands of tar distillate washes, but it would hardly be wise to conclude that all of them are efficient.

Searching for Insect Eggs.

It is always worth while to search the trees in winter for the eggs of some of the worst insect pests, as this serves as a warning as to which pests, if any, may be expected to give exceptional trouble in the spring. It is not always a safe guide, as much depends on conditions at hatching time. A good pocket lens is, of course, necessary to aid the search. Most of the eggs are to be found near the fruit buds. This winter I have not found any of the eggs exceptionally numerous. Those of the Apple sucker are the most easily found, but they are only about normal in numbers. Apple aphides in general seem to be rather below normal with me, and the same may be said of Winter Moth eggs. Those of the leaf-curling Plum aphis are always so widely scattered that little idea can be gained as to the chance of a serious attack. Reports read so far from observers in other districts, whilst they vary, as they always must, show that in some places the eggs of aphides are a good deal more numerous than they have been in the last two years, and in some cases more females of the winter moth have been caught on grease bands; but, on the whole, the reports are not very alarming.

Stored Apples.

My attempts to keep the Apple store at a low temperature, mentioned in previous notes, whilst not without result, were not altogether successful. For one thing, they started too late; but the chief reason is that the insulation of the room is not good enough to keep the temperature down for long after it has risen outside. However, I think the Apples have kept rather better than might have been expected, considering that the keeping properties of most varieties appeared to be decidedly poor in the autumn. Fortunately, only about 200 bushels of Bramley's Seedling were stored. These are being sold now, though they might, perhaps, have kept for a few weeks longer without too much loss; and they realise only sixpence a bushel more than when they were put away! Once again, therefore, storing has not paid me. *Market Grower.*

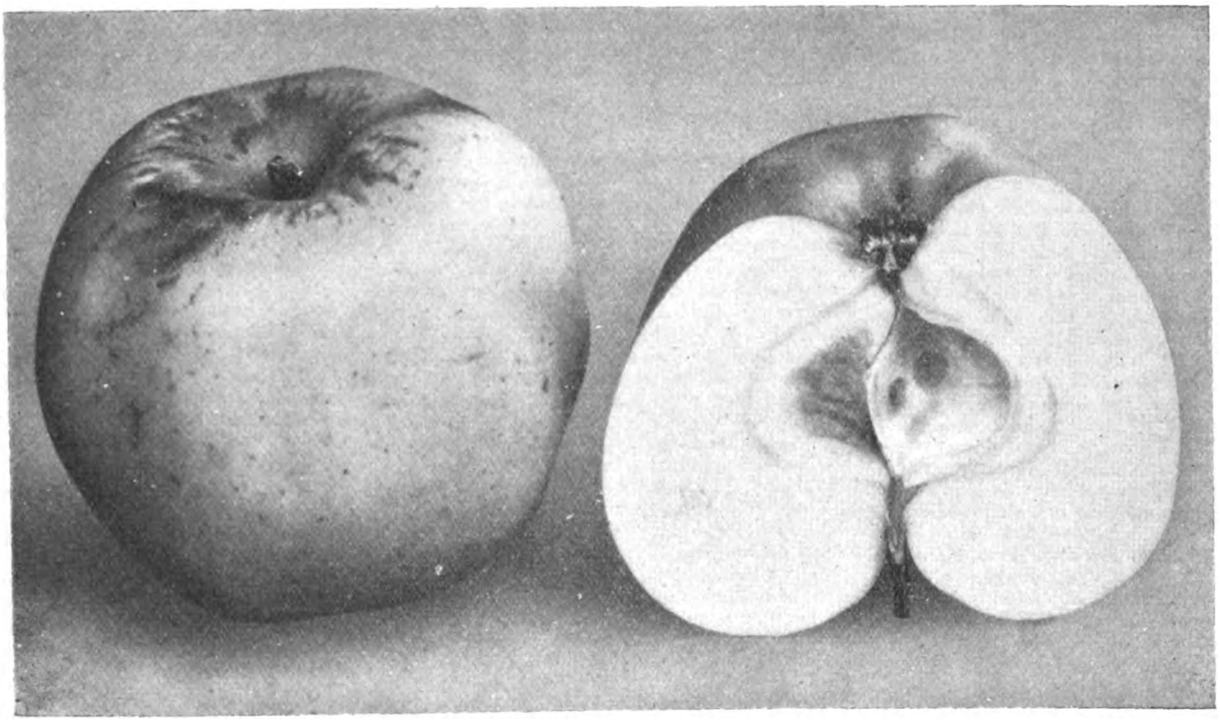

FIG. 62.—APPLE STONE'S (SYN. LODDINGTON).

FRUIT REGISTER.

APPLE STONE'S.

By many growers this Apple (Fig. 62) will be best known as Loddington, but the name most commonly employed in Kent, where the variety originated, is Stone's. Loddington is a village near Maidstone and the original tree was found there on a farm belonging to a Mr. Stone, hence the two names.

This somewhat conical-shaped variety is of large size and valuable for culinary use late in the year, keeping under favourable conditions so late as January.

It is a popular sort with market growers and makes a fine orchard Apple, bearing abundantly and needing little pruning.

The tree, however, has a tendency to canker in some soils, and for this reason it is not so generally grown now as at one time.

A GOOD SOUR CHERRY.

A correspondent (Mr. H. Reinhardt) writing in the issue of *Möllers Deutsche Gärtner-Zeitung* for the 21st of January, says: "Eleven years ago, in 1915, there was a description in this journal of Cherry Exzellenz von Hindenburg, since when it has been very widely grown in Germany, and its qualities much praised. It compares very favourably with the true 'Lotkirsche' or 'Schattenmorelle,' especially in earliness, as it is ripe fully three weeks in advance; it has a noble, wine-like, aromatic flavour, fine red juice, and a particularly small stone. I have myself grown it for twenty-three years, and have never seen Monilia or any other disease on it. For all purposes—eating raw, cooking, preserving, etc.—it is the best sort I know. My plantations occupy an elevated, exposed position, which I find is very suitable."

VEGETABLE GARDEN.

THE SPROUTING OF SEED POTATOS.

Potato tubers intended for seed sprout best in a light chamber in which the temperature does not fall below 35° or exceed 45°. Such conditions promote the formation of sturdy sprouts, which will have attained the right size by planting time.

Where large quantities of tubers have to be sprouted, it is advisable to construct or purchase special trays for the purpose. Many firms in South Lincolnshire specialise in the manufacture of these boxes, and they are so made that one can place the trays in tiers as high as the chamber in which they stand, and every tuber will receive sufficient light for proper sprouting. It is cheaper to purchase than to construct these trays; last year I purchased one hundred at 11d. each, f.o.r.; each tray was two-and-a-half feet long by one-and-a-quarter foot wide. I made an average calculation, which showed that one sprouting box will accommodate two stones of seed Potatos. Obviously such a calculation is only approximate, as much depends on the size of the tubers and whether they are round or kidney-shaped.

I think all gardeners are agreed that the sprouting of seed Potatos is not only beneficient but economically sound. In case any readers should be in doubt, I may state the reasons for my own advocacy. Sprouting results in an earlier crop, which is of considerable importance where first-early varieties are concerned; I consider that at least a fortnight is gained. The process is also helpful in the detection of tubers that may be affected by sprain. One of the effects of this malady is to paralyse completely, or in a measure, the functions of growth.

Any tubers that either refuse to sprout or make very weak sprouts should be rejected and thus prevent waste of ground. Further, sprouting often assists the grower to rogue his stock before planting, for certain varietal characteristics reveal themselves in the sprout. Finally. sprouting promotes an even foliage growth. This is a decided advantage, because it saves the naturally weak members from being overwhelmed by the strong. *Geo. H. Copley, N.D.H.*

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents].

Perpetual-flowering Carnations.—In reply to Mr. H. Howard Grace's letter (p. 51), I have no difficulty in keeping down red spider by syringing Carnations summer and winter with salt water, but more often with water only. I have never had occasion to use any of the specifics considered by many to be necessary in combating Carnation diseases. My predecessor in one situation had been using a certain specific by the gallon, judging from the many empty jars I found, but all it had done, so far as I could see, was to take the paint off the iron-work and set up corrosion. I found it very difficult to keep down red spider even by syringing twice a day, until the iron work was scraped and repainted. When syringing to keep down red spider, the water must be applied with force; mere spraying is useless, therefore all plants should be staked securely. I have received very poor plants from certain trade growers, and in one batch ordered very few were true to name. I use artificial heat up to 55° in winter, provided there is enough piping to raise it to that figure without unduly heating the pipes, but the top ventilators are never entirely closed except in frosty weather. When a fairly high temperature is promoted, the blooms are of full size, but they are weak at the neck and have to be wired for use in vases: only such stiff-stemmed varieties as Baroness de Brienin will stand up under such circumstances without wiring. I did not mean to imply in my last note that artificial heat was unnecessary. *Grigor Roy, Cobham.*

Does Frost Kill Insects.—*Market Grower* is quite right, and "General Opinion" is, *as usual*, wrong! Because human beings coddle themselves in overheated dwellings and consequently "feel the cold," they suppose that Nature's children must also suffer in frost and snow because of the cold. Nature's children however, have been well brought up to exercise common sense in this matter, and their instincts lead them to protect themselves in a variety of ways during the winter. Consequently the harder the weather the better for them directly, because it keeps them dormant, and indirectly, because their chief enemies, the birds, are decimated by long, continued, hard weather. Normal winter weather, with snaps of unseasonable warmth, however, *may* awake some of the sleepers to activity to succumb to the first frost afterwards. *C. Nicholson.*

Zinc Rings for protecting plants from Slugs.—The problem of protecting certain plants from slugs is a troublesome one to many, and I am glad to see that Mr. Puddle refers to it in such a practical manner in his notes on "The Flower Garden," on page 41. For many years I have employed zinc rings for protecting plants subject to the attacks of slugs, and I can thoroughly agree with the statements by Mr. Puddle. I am particularly pleased that he has referred to the practice of cutting the upper edge at intervals and bending the cut part over so as to form a sharp, rough barrier, over which the slugs cannot pass. The use of zinc rings has been frequently advocated, but in many instances the writers have said nothing about cutting the upper edge in this way. This I discovered for myself after trying plain and perforated zinc, as recommended by many. The rings should be cut on the upper edge to about half-an-inch, as Mr. Puddle suggests, and the zinc bent down so as to form a sharp, rough obstacle to the passing of the pests. I may add, for the benefit of those who do not possess a soldering set or who cannot get their rings readily soldered, that tongues at one end of the zinc may be made to fit into incisions near the other, and that this method answers quite well. These zinc rings should, as Mr. Puddle states, be sunk about an inch deep in the soil, and it is also desirable especially with rock plants, that no part of another plant is allowed to hang over the ring, as this may afford a means of access to the guarded enclosure. *S. Arnott.*

Mildew on Vines and Roses.—I have not seen mildew on vines since the early nineties, when I was a journeyman in gardens near Warrington; Black Hamburgh, Muscat of Alexandria and Alicante were badly affected. Mr. Taylor's treatment with sulphur, as described in his book on vines, effected a cure; the only ill-effect which I remember was a small brown, hard speck on some of the berries. The fruit gave the owner satisfaction, who stated the berries were very sweet and of good colour. Regarding mildew on Roses, I have for several years, towards the end of May or early in June, when the small white fungus first appears, sprayed all my Rose bushes with a solution of sulphide of potassium (liver of sulphur), not more than two ounces to the gallon of water, applying the specific immediately the sulphide has dissolved. For a short time afterwards the smell left by the fungicide is not pleasant, but this soon disappears, and no unsightly marks remain on the foliage. *J. E. L.*

The Late Mr. James Whytock, V.M.H.—By the death, on the 31st January (as recorded in your issue of February 6), after a brief illness, of Mr. James Whytock, Scottish horticulture has lost one of its ablest exponents, and a link with a former generation of gardeners has been severed. He was one of the most likeable of men, and had a host of friends. Mr. Whytock, who was in his 81st year, retired from active service about five years ago, since which time he has resided in Edinburgh, and he maintained an active interest in horticultural matters up to the last. He was born at Tulliallan, Kincardine-on-Forth, and began his gardening career at Oxenfoord Castle, the residence of the Earl of Stair, near Dalkeith. He afterwards served at Dalkeith Palace, under the late Mr. William Thomson, and from there he went to Abbey Leix, in King's County, the residence of Lord de Vesci. In 1879 he was appointed gardener at Coollattin, the Wicklow residence of Earl Fitzwilliam, where he continued until he was called upon to succeed the late Mr. Malcolm Dunn at Dalkeith Palace, the Midlothian residence of the Duke of Buccleuch, in 1899, and during his term of twenty-one years there he passed many young gardeners through his hands, including Mr. C. Cook, now of Windsor. He was a member for several terms of the Council of the Royal Caledonian Horticultural Society, including the period of the 1905 International Show, and also of the Scottish Horticultural Association, of which he was president for three years, from 1908 to 1910. He was also president of the Botanical Society of Edinburgh in 1919 and 1920, and it was during his presidency that the new genus of Gesneraceous plants, Whytockia, was instituted and named in recognition of his services to horticulture. He was also a Fellow of the Royal Horticultural Society, from which he received the Victoria Medal in Horticulture in 1914, and a member of the Royal Scottish Arboricultural Society. He was awarded the Neill Prize in Horticulture by the Council of the Royal Caledonian Horticultural Society in 1906. Mr. Whytock is survived by Mrs. Whytock and by a grown-up family of four sons. *A. D. R.*

SOCIETIES.

ROYAL HORTICULTURAL.

February 9.—Following precedent there was a very good show at Vincent Square, on the occasion of the Annual General Meeting. Fruits were more extensively shown than of late, and the rich golden colour of the Oranges growing freely on the bushes, together with the collections of highly coloured Apples and the groups of spring flowers gave an impression of a genial sunny climate which was in welcome contrast to the cold and dreary out-of-door world. Orchids were shown extensively and the general floral exhibits included Primulas, Rhododendrons, forced shrubs, Carnations and Alpines.

Orchid Committee.

Present:—Sir Jeremiah Colman (in the Chair), Mr. Gurney Wilson (Hon. Sec.), Mr. R. Brooman White, Mr. C. J. Lucas, Mr. H. J. Pitt, Mr. S. W. Flory, Mr. A. Dye, Mr. F. K. Sander, Mr. H. G. Alexander, Mr. J. E. Shill, Mr. J. Cypher, Mr. Chas. H. Curtis, Mr. A. McBean, Mr. J. Cowan, Mr. H. H. Smith, Mr. J. Armstrong, Mr. Robert Paterson, Mr. E. R. Ashton, Mr. Stuart H. Low, and Mr. Fred J. Hanbury.

AWARDS OF MERIT.

Brasso-Cattleya Warnham Beauty. (*B.-C. Digbyano-Mossiae × C. Tityus*).—A magnificent hybrid with flowers of large size and substance. The sepals and petals are deep mauve and the lip deep purple at the apex, with purplish mauve side lobes and a yellow stain in the white throat. Shown by C. J. Lucas, Esq., Warnham Court, Horsham.

Cattleya Minnehaha (Trianae The Baron × Lady Rowena).—In this lovely hybrid the flowers are of beautiful form. The sepals and petals are white, the latter slightly fringed, broad and rounded; the lip is white, with a frilled margin and a soft orange-yellow throat. Six plants of this fine Orchid were exhibited. Shown by Baron Bruno Schröder (gr. Mr. J. E. Shill), The Dell Park, Egham.

Cymbidium Miranda var. Lemon Queen. (*Lowio-grandiflorum × Alexanderi*).—In this large-flowered form the sepals and petals are pale greenish lemon colour with a few small brown dots at the base of each; the lip is white with deep red brown spots. The plant exhibited carried fourteen splendid flowers. Shown by Sir George Holford, Westonbirt.

Cymbidium Flamingo var. White Wings (*Alexanderi × Merlin*).—An exquisitely beautiful variety with white sepals and petals, and white lip stained with purplish red. In form and size this is also a fine variety. Shown by Sir George Holford (gr. Mr. H. Alexander), Westonbirt, Tetbury.

Odontoglossum Gatton Prince (*Gatton Princess × Gatton Emperor*).—A distinct hybrid with shapely flowers of deep maroon-red colour, tipped with white, and with white bases to the three upper segments; lip maroon-red edged with white; disk yellow. Shown by Sir Jeremiah Colman, Bt. (gr. Mr J. Collier), Gatton Park, Reigate

Odontonia Nesta (*Oda. Gladys × Odm. St. George*).—A handsome Orchid with flowers in which every part is well displayed. The sepals and petals are rich chocolate-red with a few white or pink markings; the broad lip is similarly coloured, and there is a semi-circular, irregular line, of white towards the base of the lip as though the plant was endeavouring to reproduce the "mask" of a Miltonia. The apex of the lip is white, pink tinted, and shaded with red. Shown by Messrs Charlesworth and Co.

Odontoglossum Alvara (*Ithone × Clovis*).—A richly hued hybrid of fine size and substance. A narrow margin of white surrounds the deep chocolate-red of the sepals and petals; the upper sepal is also tipped with white, but the lower sepals have a pinkish apex. Lip white with numerous chocolate-red markings and a yellow disk. Shown by Messrs. Charlesworth and Co.

Groups.

Messrs **J. and A. McBean** set up a large and effective display in which lovely spikes of Odontoglossums, Cymbidiums, and Odontiodas were the chief features. The group was beautifully arranged and the plants well grown. Among the many handsome subjects shown, we were specially attracted by the brilliant Laelio-Cattleya Smilax var. Prince of Wales, Cymbidium Floryi, Cattleya Empress Frederick, Odontoglossum Vega—a fine cross between O. King Arthur and O. Midnight, O. Pyramus, O. Rosina and O. Marcus, the last a cross between O. Jasper and O. Harryanum. Odontioda Lambeauiana, O. Diana, Lycaste Skinneri alba and Cymbidium Alexanderi were other good things in this group.

Messrs. **Sutton Brothers**, Hassocks Nursery, entirely new exhibitors and a firm of quite recent foundation, contributed a group of Orchids that proved of general interest. Cymbidiums were used as a background for Dendrobiums of the D. nobile type, Odontoglossums, Odontiodas and Cypripediums. A central feature consisted of two specimens of the old Odontoglossum triumphans, each carrying a pair of spikes of bright and elegant flowers. Other conspicuous subjects were Oncidium Papilio, Odontioda Bradshawiae, Cypripedium Euryades, New Hall Hey var. Laelio-Cattleya Monica, the charming Sophro-Laelia Marriottiana, Brasso-Laelio-Cattleya Rumania with a light yellow area on the large lip, and a large plant of Odontocidium Edwardii.

Cypripediums formed the greater part of the group submitted by Messrs. **J. Cypher and Sons**, and of these useful subjects we noted capital examples of C. Cupid, C. Elsie magnificum, C. Alcibiades, C. Bridgei, C. Queen of Italy, and C. Hercules, the last betraying its descent from C. hirsutissimum. Cymbidiums and Calanthes were well shown, and a plant of the rare Masdevallia gargantua created a great deal of interest.

Miltonia Wm. Pitt was finely shown in Messrs. **Charlesworth and Co.**'s group, but there were many other fine things, notably Dendrobium Gatton Monarch, of fine size and colour, Cattleya Blackii with half-a-dozen of its chaste flowers, Lycaste Balliae superba, Odontoglossum Minatour, O. Miguelito, Cattleya Zephyr and C. Tityus. There were in addition many other excellent plants, all well grown and carrying splendid flowers.

Messrs. **Sanders** contributed such interesting Orchids as Angraecum sesquipedale, Odontoglossum bictoniense, the bright Laelia Icarus (flava × cinnabarina), Cymbidium Erica Sander var. Zephyr, the big Brasso-Laelio-Cattleya Nadir, Calanthe Butterfly and the rare Dendrobium aqueum

Messrs. **Cowan and Co.** submitted a group consisting largely of Cypripediums and these included the showy C. St. Kentigern, C. bingleyense, C. Commodore, C. Carola and the pale C. Tom Worsley. Oncidium Cavendishianum, figured in the background, with examples of Cattleya Clotho, Odontioda Murillo—lovely colour, and Dendrobium Austinii (Ainsworthii × Cybele nobilius).

Two dozen charming plants of Epidendrum Endresio-Wallisii made a central feature in the group from **H. T. Pitt**, Esq. (gr. Mr. Thurgood), Rosslyn, Stamford Hill. With these were associated Sophronitis grandiflora, Cymbidium Lady Colman, and the handsome Odontoglossum harvengtense, Pitt's var.

Messrs. **Stuart Low and Co.** had a corner group in which Rolfeara Charm, with light flame-coloured flowers, was the centre of attraction; Cattleya Percivaliana var. Little Gem, Laelio-Cattleya Radina, Odontoglossum scintillans, and Sophro-Cattleya Saxa were all finely shown.

Sir **Jeremiah Colman** (gr. Mr. J. Collier), Gatton Park, Reigate, showed a few charming Orchids, including a fine specimen of Brasso-Cattleya Gatton Lily var. magnifica, with nine fine flowers (Cultural Commendation). Messrs. **A. J. Keeling and Son** and Messrs. **Black and Flory** also exhibited a few Orchids, and there were numerous single plants submitted for the judgment of the Committee.

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the Chair), Mr. J. F. McLeod, Mr. Arthur Turner, Mrs. E. M. Wightman, Mr. H. J. Jones, Mr. J. M. Bridgford, Mr. D. Allan, Mr. Wm. Howe, Mr. M. C. Allwood, Mr. W. H. Page, Mr. E. R. Janes, Mr. F. Streeter, Mr. F. J. Cousins, Mr. D. Ingamells, Lady Beatrix Stanley, Mrs. H. L. Smith, Mr. James B. Riding, Mr. Hugh Dickson, Mr. A. Vasey, Mr. W. B. Gingell, Mr. Mark Fenwick, Mr. G. W. Leak, Mr. D.B. Crane and Mr. Chas. E. Pearson.

Section B.—Mr. Chas T. Musgrave (in the chair), Mr. James Hudson, Mr. G. Reuthe, Mr. E. H. Wilding, Mr. C. Williams, Mr. Amos Perry, Mr. L. R. Russell, Mr. G. Yeld, Mr. A. Bedford, Mr. F. G. Preston, Mr. W. G. Baker, Mr. W. J. Bean, Mr. G. W. E. Loder and Mr. R. C. Notcutt.

Awards of Merit.

Cyrtanthus lutescens.—This interesting and attractive bulbous plant was introduced from the Cape of Good Hope in 1836, and for a time was in general cultivation, but latterly it has become a somewhat rare plant, outside botanical gardens. It bears an umbel of four to six long, narrowly tubular, yellow flowers on a green stem about twelve inches high. The narrow linear leaves are dark green in colour. Shown by Mrs. **Frank Platt-Barlow**, 50, Hans Place, London, S.W.

Lindenbergia grandiflora.—An herbaceous and sub-shrubby plant which is common on the foothills of the Himalaya from Simla to Bhotan at elevations of two thousand feet and upwards. It is a useful greenhouse plant for this country and well grown examples, similar to that shown, are quite decorative. The ovate, coarsely toothed leaves are of soft texture, hairy and somewhat pointed. The yellow flowers, which are borne in terminal, leafy spikes are about an inch across and have much the same general structure as those of the genus Mimulus. Shown by the **University Botanic Gardens**, Cambridge.

Mutisia Clematis.—This fascinating and, when in flower, gorgeously beautiful climber was the subject of a coloured supplement to the *Gardeners' Chronicle* of November 29, 1913, which shows the flowers with their bright red, almost scarlet, colour. Probably owing to its early flowering the colour of the flowers shown was paler than usual, but even so they were very showy and attractive. Mutisia Clematis, a native of the higher ranges of the Andes of South America, is hardy on occasion but usually thrives best in a cool and sunny greenhouse. In the warmer parts of the country it is occasionally seen as a wall plant. It is a vigorous climber bearing pinnate, Vetch-like leaves and oblong cylindrical flower heads all felted with silvery, silky hairs. The ray florets are about two inches long and of dazzling colour. Shown by Lt.-Col. **Messel**.

Rhododendron Pink Delight.—A compact, well-formed truss of large pips of paper-white colour, margined with shades of pale pink. Shown by Messrs. **R. Gill and Son**.

Other Novelties.

An interesting collection of flowers was sent from La Mortola, the Italian garden of Mr. Cecil Hanbury. Unfortunately these had been delayed a fortnight in transit but many specimens retained their beauty and attractions. The exhibit included flower spikes of Aloe natalensis, A. spinossisima and sprays of Nandina domestica bearing exceptionally large quantities of bright berries. Although it did not find favour with the Committee, Primula sinensis stellata Symmetry, shown by Messrs. **Sutton and Sons**, is a very beautiful variety. The flowers, which are freely produced, large and substantial, of a rich pink colour with a narrow carmine zone and a pale primrose eye. Mr. **C. T. Musgrave**, Hanscombe Place, Godalming, showed Snowdrops of great interest in pots. These were all large-flowered kinds and included Galanthus Elwesii, G. nivalis, G. Imperati, Bitton variety, and G. byzantinus.

Groups.

Messrs. **Sutton and Sons** set up an admirable collection of greenhouse Primulas. This was of splendidly grown plants and set in fresh green moss laid out in the form of a series of dells. The inception was admirable and the exhibit attracted a great deal of attention. The stellata varieties were freely used and included Symmetry, a lovely rose-pink variety, Little Blue King and Duchess. Amongst the many good, large-flowered varieties were Intensity, of rich colour, Etna, a dazzling red which also has dark foliage, and Giant Royal White.

Adjoining their Carnations, Messrs. **Stuart Low and Co.** staged some good Hippeastrums, Boronia elatior, Acacia Baileyana and a large batch of greenhouse Cyclamen. Their Carnations included excellent blooms of Sybil, of velvety, smoky, purple colour, White Pearl and Topsy. Amongst the many Carnations set up by Messrs. **Allwood Bros.** we especially noted Canadian Pink, of large size and good self colour; Cottage Maid, a pale blush pink with a darker centre; and Beauty of Durham, of vivid salmon-cerise colouring. Mr. **C. Engelmann** included Janet, Sheila Greer, Saffron, Laddie and Betty Lou in his collection of splendid Carnations.

Particularly good forced Roses were shown by Mr. **Elisha J. Hicks**, who set up large vases of Climbing Lady Hillingdon, Madame Butterfly, Clovelly, Mrs. Herbert Stevens and The Queen Alexandra Rose. Mr. **George Prince** exhibited large stands of graceful sprays of yellow Banksian and Fortune's Yellow Roses.

In a corner group Messrs. **Chaplin Bros.** had a group of well grown Camellias which included Princess Charlotte, white; Eugenie Messine, pink; Camille Aureliana, slightly deeper in shade; and Flora, white, of the double flowered varieties, while the singles were represented by Vesta, rose-pink; Waltham Glory, red; Apollo, crimson, and the Swan, white. A goodly group of Violets, chiefly of the large-flowered variety Princess Mary, was shown by Mr. **J. J. Kettle**.

Perhaps the most attractive amongst the various hardy shrubs were the Rhododendrons. Messrs. **R. Gill and Son** showed beautiful trusses of R. Cornubia, R. argenteum, R. Pink Delight and R. praecox and also staged a good collection of their admirable strain of St. Brigid Anemones. Brightly coloured Rhododendrons were also shown by Mr. **G. Reuthe**, who included trusses of R. Mrs H. Shilson, R. Cornubia, and R. barbatum in his miscellaneous exhibit. Berberis hyemalis, Garrya elliptica, Iris reticulata, var. Cantab, and many alpines were also of merit

Forced bushes of Wistaria, Lilacs, Azalea mollis and A. indica were tastefully arranged by Messrs. **L. R. Russell, Ltd.** Viburnum Carlesii, Prunus Davidiana alba, and other shrubs were associated with alpines by Messrs. **Bakers, Ltd.**, while Messrs. **Wallace and Co.** had a good selection of dwarf Conifers, suitable for the rock garden, with Erica King George, Daphne Mezereum album, and a good bush of Rhododendron moupinense.

A well-arranged rock garden was planted by Messrs. **Wm. Cutbush and Sons** with Wistarias, Azaleas of several types, Pieris (Andromeda) japonica, Erica carnea, and many alpines of value. In a low rock garden Mr. **F. G. Wood** set out Snowdrops, Muscari, Saxifrages, and Primroses, making a pleasing feature. Messrs. **Waterer, Sons and Crisp** planted in fibre many little batches of Crocus, Iris reticulata, I. sindpers, Narcissus triandrus albus, N. cyclamineus, and other appropriate plants.

Saxifrages, such as S. oppositifolia major, S. Haagii, S. Irvingii, S. Wm. Marshall and S. Riverslea, were well shown by Messrs. **M. Prichard and Sons**. Messrs. **J. Cheal and Sons** showed pans of Crocuses, Muscari, Iris reticulata, Dicentra spectabilis and Saxifrages, with Primroses in the background. A neat rock garden was shown by the Misses **Hopkins**.

The Rev. **H. R. Meyer** (gr. Mr. J. P. Izzard), Walton-at-Stone, Herts, showed many plants of Iris reticulata set in fibre, making a very attractive display. Mr. **C. Elliott** exhibited Saxifraga Burseriana Gloria, S. oppositifolia Salomonei, Primula Winteri and other alpines.

Particularly well flowered bushes of Forsythia spectabilis, with Ericas and Alpines were staged by Messrs. SKELTON AND KIRBY. Messrs. R. TUCKER AND SONS showed shrubs and Saxifraga Brookside, S. Burseriana sulphurea and S. Mrs. Leng of considerable beauty.

A fascinating collection of the dwarf early Irises was well arranged by Messrs. BARR AND SONS. The chief varieties were I. pumila cœrulea, I. Louise, I. Standard, I. Socrates and I. unguicularis alba with a large batch of I. reticulata of intense colour. They also included some uncommon Hellebores in their exhibit.

The exhibits of paintings included several of exceptional interest. Mrs. E. M. PHILLIPS exhibited a large collection of excellent paintings of West Indian flowering trees and plants. Miss C. G. TROWER had over sixty faithful drawings and water-colour paintings of native members of the order Rosaceae, and Miss FRANCES BUNYARD showed splendid paintings of Apples and Plums.

Narcissus and Tulip Committee.

Present: Mr. George Monro (in the Chair). Mr. Charles H. Curtis, Mr. Peter R. Barr, Mr. John W. Jones, Mr. G. W. Leak, Mr. F. Herbert Chapman, Mr. Rollo Meyer, Mr. H. B. May, Mr. G. Churcher and Mr. A. Simmonds (Sec.).

The Chairman made feeling reference to the loss sustained by the death of the Rev. J. Jacob, an old and greatly valued member of the committee; it was agreed that a letter of sympathy be sent to the sister of the deceased gentleman.

In the centre of the hall Messrs. J. CARTER AND CO. had an excellent collection of early-flowering Tulips set out in circles each with a central plant of profusely-flowered Prunus triloba, and surrounded by a band of contrasting varieties. The many valuable sorts included Grand Duc, Prince of Austria, Fred Moore, Red Admiral, General de Wet and Rising Sun.

Fruit and Vegetable Committee.

Present; Mr. C. G. A. Nix (chairman). Mr. W. Poupart, Mr. J. Cheal, Mr. P. C. M. Veitch, Mr. H. S. Rivers, Mr. J. Harrison, Mr. G. F. Tinley, Mr. T. Pateman, Mr. E. Laxton, Mr. W. Lobjoit, Mr. A. Metcalfe, Mr. H. Prince, Mr. E. Beckett, Mr. F. Jordan, Mr. W. H. Divers, Mr. H. V. Taylor, Mr. E. A. Bunyard, Mr. A. N. Rawes and Mr. P. D. Tuckett.

Several seedling Apples were submitted for award and one or two were of very promising appearance, but lacking in quality. Messrs. W. AND J. BROWN, Stamford, exhibited a seedling Apple named Oakham Seedling, a very showy fruit, very much like New Bess Pool.

Mr. F. G. GERRISH, O'Keys Farm, Fernhill Heath, Worcester, showed some excellent fruits of Lord Hindlip Apple which had been stored in clamps like Potatos. Mr. Gerrish stated that this variety is grown extensively in the Worcester districts and the trees this year bore very large crops. Although of sound appearance, the clamped fruits appeared to have lost a considerable amount of flavour. Much the finest Apple submitted was Laxton's Superb, which has already received the R.H.S. First Class Certificate.

GROUPS.

Two excellent collections of Apples were staged; the largest, comprising one hundred varieties, was shown by Mr. J. C. ALLGROVE, Middle Green, Langley, Slough, and the other by Messrs. G. BUNYARD AND CO., LTD., Maidstone, who exhibited sixty-two varieties. Both exhibits were very attractively displayed: Mr. Allgrove's was decorated with Palms and other foliage plants and included such excellent varieties as Blenheim Pippin, Rival, Cox's Orange Pippin, Beauty of Kent, Belle Pontoise, Hoary Morning, Ball's Pippin, Gabalva, Winter Peach, Cornish Aromatic, Encore, Newton Wonder, King of Tomkin's County, Blue Pearmain, Chas. Ross, Gascoyne's Seedling, Lord Burghley, Ontario and William Crump. The finest varieties in Messrs. Bunyard's collection were Belle de Boskoop, Blue Pearmain, High Green Blenheim, Cornish Aromatic, Sir John Thornycroft, Edward VII., New Bess Pool, Easter Orange, Bowhill Pippin, Lord Hindlip, Allington Pippin, Braddick's Pippin, Adam's Pearmain, Cobham, Ballinora, Calville Rouge's, King's Acre Pippin, Wagener and Cockington.

An exhibit of unusual interest was shown by CECIL HANBURY, Esq., a collection of Citrus fruits from his garden at La Mortola, Ventimiglia, Italy. The collection was dispatched from La Mortola for the meeting on the 26th ult., but unfortunately, as happened last year, it arrived too late. Because of the delay the exhibit was robbed of much of its interest, as the stems and foliage attached to the fruits had dropped and obviously the fruits themselves were not in such fresh condition. The collection included fifty-one species and varieties of the Citrus family. One of the best of the true Oranges was Citrus Aurantium var. sinensis "Arancio San Michele Di Teneriffe." The sweetest variety was Citrus Aurantium var. sinensis "Arancio Turco Dolcissimo" a practically seedless Orange, and others shown included Citrus Aurantium var. sinensis "Arancio Vaniglia," an aromatic and sweet variety with a thick skin; Citrus medica var. Limoni "Limone in Arancio," a Lemon without seed pips with a very thin skin; Citrus medica var. Limette "Limone Dolce," a sweet Lemon; C. nobilis Mandarin, sweet and juicy; and C. nobilis Tangerine, a Tangerine of distinct flavour. In addition, a collection of ornamental Gourds was included, the most interesting being Cucurbita Pepo var. pyriformis "mamellata," which is not a free setting sort, but which will give good results when hand-fertilised; Cucurbita Pepo var. cucurbitella "striata lutea," a most difficult variety to keep true and therefore should be grown isolated; and Cucurbita Pepo var. ficifolia, a Fig-leaved Gourd used for making jam. It is a strong grower, sets freely and keeps fresh for two years.

Messrs. T. RIVERS AND SON, Sawbridgeworth, showed Oranges fruiting in pots and numerous gathered fruits of Oranges, Lemons, Citrons, Limes, Shaddocks, etc. The trees were excellent specimens, and in most cases they bore flowers as well as fruits. The best of the Oranges, from a superficial view, appeared to be Long Orange, Egg Orange, Excelsior and Thomson's Improved Navel.

ANNUAL MEETING.

THE Lecture Hall was packed with Fellows on the occasion of the Annual General Meeting held at 3 p.m. Lord Lambourne presided, and was supported on the platform by Sir William Lawrence, Sir George Holford, Mr. E. A. Bowles, Mr. E. A. Bunyard, Mr. George Morris, Mr. G. W. Leak, Hon. H. D. McLaren, Mr. T. Hay, Mr. C. Nix, Mr. W. A. Bilney, Dr. Hill, Mr. C. T. Musgrave and Mr. A. Simmonds (Assistant Secretary).

The usual formalities were disposed of quickly, and one-hundred-and fifty-two new Fellows, seven Associates and five Affiliated Societies were elected *en bloc*.

Lord Lambourne moved the adoption of the Report of the Council and Accounts for 1925, and reviewed the work of the year. He observed that a year ago the Society had 21,000 Fellows, and since then 4,000 new Fellows had been admitted. The Council had under careful consideration the selection of a Secretary to fill the vacancy arising owing to the lamented death of Mr. W. R. Dykes. Keen attention was paid to Lord Lambourne's remarks concerning the new hall, the building of which, he considered, would be one of the most important items of business the Council ever had to consider. Progress was being made with the plans, but it had been slow because the approval of several authorities had to be obtained, and this had, on several occasions, led to such considerable alterations as to necessitate re-planning. He assured the Fellows that the new hall would be admirably lighted, well-heated and amply ventilated; the building would include rooms for the accommodation of the Standing Committees, and these would be so arranged that they would provide the necessary accommodation for those who hired the hall for meetings and exhibitions. In conclusion, Lord Lambourne paid high tribute to the work of the retiring members of Council, Mr. E. A. Bowles, who would become a vice president of the Society and remain as chairman of the Narcissus and Tulip Committee; Mr. H. B. May, who had worked on the Council for nearly a quarter-of-a-century and who would still continue as Chairman of the A Section of the Floral Committee; and Mr. C. T. Musgrave, formerly Treasurer, whose legal knowledge had been of immense service, and who would remain Chairman of the Housing Committee, which was dealing with the new hall. Lord Lambourne also expressed the indebtedness of the Council and Fellows to the staffs at Wisley and Vincent Square, and referred in very appreciative terms to Mr. Frank Reader's thirty-six years of continuous service as cashier.

Sir William Lawrence, Treasurer, dealt with the accounts and also referred to the new hall. He did not know what the cost would be, and although he had a figure in mind, he did not propose to state it. The Society was, however, in a happy financial position in having about £138,000 in investments and in reserve; with this sum and the spreading of certain capital expenditure over a series of years, he felt that, if the present success of the Society continued, the large expenditure necessary for the new hall need not frighten anyone.

Mr. C. T. Musgrave, by means of a model, demonstrated the method of lighting the new hall. He hoped the completed plans, approved by all the authorities concerned, would be ready in a few weeks, and that excavations on the site (behind the present hall) would commence in July. Mr. Musgrave stated that whereas the present available space for exhibitions was about 10,000 square feet, the new hall would provide a total available area of 21,000 square feet.

The motion was then put and carried, and as the nominations for President, Vice-Presidents, Members of Council, Auditors, etc., were no more than sufficient to fill the several positions, no voting was needed, consequently the President declared them all duly elected. The new members of Council are Mr. M. Fenwick, Mr. G. W. E. Loder, and Mr. W. R. Oldham.

Lord Lambourne then presented the Victoria Medals of Honour in Horticulture—Mrs. Dykes received the one awarded to her late husband; Mr. Dick's son received the one awarded to his late father; in the absence, owing to failing health, of Mr. George Mount, his medal was handed to his son, Mr. Harry Mount; this left Mr. Joseph Rochford as the only one of the four to personally receive the coveted honour. The Lawrence Medal was presented to Mr. E. A. Bunyard; the Sander Memorial Medal to Sir George Holford; the big Cory Cup to Mr. E. A. Bowles, and the Loder Cup to Mr. W. J. Bean; Mr. E. H. Wilson and Mr. W. P. Thomson, to whom Gold Veitch Memorial Medals had been awarded, were not present to receive them.

Mr. R. Fife then proposed "That this General Meeting is of opinion that the situation and soil of Wisley render it unsuitable for a Trial Garden, and remits to the Council to endeavour to procure suitable land in a place more easily accessible to visitors and to report to a future meeting." Mr. Fife spoke at considerable length, and expressed the opinion that the Trials at Wisley were practically useless and the garden of little value except as a wild garden. He made no complaint concerning the staff or the conduct of the trials, but considered the soil and situation were so bad that no one could carry out effective trials of fruits, flowers and vegetables under the conditions prevailing. Mr. W. J. Chittenden seconded the motion, and Mr. C. Nix, who replied on behalf of the Council, pointed out that it was absurd to expect the Council to seriously consider the acquisition of a new Wisley and he stated that the National Dahlia Society had expressed approval of the Dahlia Trials (upon which Mr. Fife was especially severe) and had requested their continuance.

Although the Fellows gave Mr. Fife a perfectly courteous hearing and almost all of them remained to the close of his remarks, it was fairly obvious that the proposer had overstated his case, in short, he did protest too much, and so failed to secure for his proposal any other support than that of its seconder.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

Friday, January 22.—*Committee Present:* R. Ashworth, Esq. (in the chair), Messrs. C. Branch, A. Burns, D. A. Cowan, J. Evans, A. Keeling, E. W. Thompson and H. Arthur (secretary).

First-Class Certificate.

Odontoglossum illustrissimum var. rubrum.—A well-shaped flower of rich port wine colour; the broad, flat lip is tipped with a deep band of white. From Mrs. P. Smith.

Awards of Merit.

Cypripedium Pioneer var. punctatum (*Zoe* × *Desdemona*) and *C. Aureoma giganteum* (*aureum* × *Desdemona*). From Mrs. P. Smith.

Odontioda Ruth and Odontoglossum promerens var. albanense. From J. B. Adamson, Esq.

Cypripedium Evelyn Moore (*Lady Dillon* × *Gaston Bulteel*). From S. Gratrix, Esq.

Groups.

J. B. Adamson, Esq., Blackpool (gr. Mr. R. Taylor), staged a group to which a Gold Medal was awarded.

A Gold Medal was also awarded to S. Gratrix, Esq., Manchester (gr. Mr. C. Branch), for a group of Cypripediums in variety.

Obituary.

Dr. William Bateson.—We learn with intense regret of the death of Dr. William Bateson, Director of the John Innes Horticultural Institution. Apparently a heart attack followed bronchitis and after a brief illness he succumbed on Monday morning, February 8th. Horticulture has thus suffered a severe loss. In these days when many of us are troubled concerning the scientific aspects of our hobby or our profession the John Innes Horticultural Institution seemed the one bright spot where the enthusiasm and industry of the Director and his colleagues ensured that this country should be pre-eminent in the important part of genetics. Dr. William Bateson was born at Whitby in 1861 and was the son of the Rev. Dr. W. H. Bateson for many years Master of St. John's College, Cambridge. Educated at Rugby he gained a scholarship at his father's college and became a well-known figure in Cambridge for many years. As an undergraduate he was rather young in appearance, a little boisterous, and gained somewhat of a reputation among his fellow-students by the catholicity of his tastes; apparently lectures on all subjects, with the exception of mathematics, had their attractions for him, though he was ostensibly a science student. He specialized in zoology and was Balfour Student in 1887-90. Working at the anatomy and development of Balanoglossus, he became interested in variation and although he had been warned that the subject had been swept clean he travelled all over Europe to study what variations *did* occur, rather than what theoretically *might*. The results are to be found in his *Materials for the Study of Variation* (1894), which by many is regarded as a classic. It is in this work that he distinguishes between continuous and discontinuous variations. From then onwards variation and its ramification was his chief study. In 1900 biologists were startled by the "rediscovery" of Mendel's Law by de Vries. The story of how the results published by the Austrian abbot, Gregor Johann Mendel, in 1866, received no recognition until the practically simultaneous confirmation by de Vries, Correns and Tschermak, has often been told in these pages and elsewhere. Bateson now had a key to his vast accumulation of data, and became the foremost Mendelian. On the appearance of de Vries's paper he immediately gave an account of Mendel's results in a lecture to the Royal Horticultural Society on "Problems of Heredity as a Subject for Horticultural Investigation." (*Journal R.H.S.* XXI., 1900.) and edited a translation of Mendel's paper which appeared the following year. With additions, these were published in *Mendel's Principles of Heredity, a Defence* (1902) wherein he took to task the late Prof. W. R. Weldon who had criticised Mendel's results from a biometrical point of view. With a band of enthusiastic workers (Miss E. R. Saunders, the late R. P. Gregory, the late R. H. Lock, Prof. R. C. Punnett and others) he was able to accumulate an abundance of experimental facts capable of Mendelian interpretation. As President of Section D. (Zoology) at the Cambridge meeting in 1904 he gave a stirring address which had far reaching effects. In 1906 Dr. Batson was President of the International Conference of Genetics: the subject had now come into its own. The first Conference was held at London in 1897 and was a very small affair; the second at New York in 1902, and Dr. Bateson was one of the R.H.S. delegates and made there a very great impression; an idea of the third conference may be gained from the report published by the R.H.S. in 1907. These various activities resulted in 1908 in the founding of a chair of Biology at Cambridge with Dr. Bateson as the first Professor. His inaugural address (which was later published in book form) was a good augury of what the endowment was to accomplish. However, the following year, the Trustees of the newly formed John Innes Horticultural Institution offered him the Directorship. Realising that such a post gave him greater scope in every way, he accepted it. What appeared in our pages at the time (Vol. XLVI., p. 360) has been fully borne out. Merton has become the Mecca of all geneticists who visit this country, although pilgrimages to his garden at Grantchester were not unknown. Shortly before leaving Cambridge he published *Mendel's Principles of Heredity* (1909) and in 1913 his *Problems of Genetics* based on the Sillman lectures he had given at Yale in 1907. In 1910 he founded the *Journal of Genetics* in collaboration with his successor at Cambridge, Professor R. C. Punnett: of his several contribution to this *Journal* the last written in conjunction with his only surviving son Gregory, appears in the most recent number. Honours naturally came to him. Amongst others he was Fellow of the Royal Society; Hon. D.Sc. of Sheffield, Melbourne and Perth; V.M.H.; and Hon. Fellow of St. Johns. He was also twice Vice-President of the Linnean Society. During the visit of the British Association to Australia in 1914 he was President, and was President-elect of Section K (Botany) for the Oxford meeting to be held this year. He was foreign member of several foreign societies—American, Danish, Belgian, Swiss and Norwegian. An honour he greatly valued, was his appointment in 1922 as a Trustee of the British Museum. Dr. Bateson had a striking appearance and a striking personality. No one could have better carried the new ideas forward. A little inclined to use heavy guns in controversy he was sure to indulge in some *bon mot* which was remembered; and all were convinced of his regard for truth and his tenaciousness in thrusting it forward. Though impatient of fools he gained the sincere affection of all those who were closely associated with him. He was generous in the cause of science. As a lecturer he had his failures—but few were his equal in the more formal lectures which from time to time he was called upon to give; these such as "Evolution and Modern Doubts" delivered to the American Association for the Advancement of Science in 1921 often reached the general public. There would be few who would deny that William Bateson was our foremost British Biologist.

Rev. Joseph Jacob, M.A.—Floriculture has suffered a grievous loss by the death of the Rev. Joseph Jacob, who passed away during the night of Friday, the 5th inst., at the age of 67 years, His familiar stalwart figure and kindly manner will be sadly missed at floricultural gatherings in this country and in Holland and particularly so during this spring. Passionately fond of flowers and a wide reader of old floricultural literature, he achieved fame as a writer, but all his writings had a good foundation of practical knowledge gained as a cultivator and raiser. After his education at Uppingham, the Rev. Joseph Jacob went to Trinity College, Cambridge, where he took honours in natural science. In 1882 he was ordained to the curacy of Malpas, and two years later became vicar of Whitewell, Shropshire, where he spent the rest of his life—forty-one years, in the kindly conduct of his clerical duties and tending the plants and flowers he loved so well. He had a large garden and quite early in his career took up the cultivation of Daffodils, of which he became an acknowledged authority in this and other lands. As a member of the Royal Horticultural Society's Narcissus and Tulip Committee, his association with Daffodil and Tulip experts was a lengthy one, and if on occasion he irritated some people by his insistence upon the recognition of minute floricultural details, as did the older florists, everyone loved him because of his enthusiasm and sincerity. He was the author of *Daffodils* and also of *Tulips*, both books belonging to the Present Day Gardening Series, and he was chiefly responsible for the several issues of the *Daffodil Year Book* published by the R.H.S. at the request of its Narcissus Committee. It was a sad day for the vicar of Whitewell when eelworm so devastated his Daffodils that he had almost to abandon their cultivation and give up the serious work of raising Daffodils, which had occupied his attention for some time. The imminence of this disaster led him to propose that the R.H.S. should investigate the Daffodil disease, a proposal that led to the appointment of the late Mr. J. K. Ramsbottom and resulted in the discovery that the disease was due to the presence of eelworms and could be controlled by treating the bulbs with hot water. Scarcely less wide was Mr. Jacob's knowledge of Tulips, and to these flowers he gave great attention in recent years. Lachenalias and Freesias pleased and interested him, and of both these flowers he raised a number of excellent varieties. But although best known by reason of his work among bulbous plants, he kept in close touch with all advances in the production of Michaelmas Daisies, Delphiniums and other hardy flowers and contributed useful and critical writings upon these subjects to our pages. For two or three years past he had not been in good health, indeed his medical adviser had bidden him be careful and reduce his activities. This advice was difficult to follow by a man who would often read and write until the small hours of the morning. Recently he became seriously ill, and although his many friends hoped for a recovery, signs were not wanting that any untoward circumstance might hasten the end, therefore, when pneumonia supervened, there was little hope of his recovery. Like many another clergyman who has taken kindly to floriculture, he has left his mark on the horticultural world, and many besides those who knew him personally will mourn his loss.

Charles Lemaire.—We regret to note that M. Charles Lemaire, the Director of the Antwerp Colonial University, died at the end of January, at the age of sixty-two. A famous African explorer and an enthusiast for the Belgian Congo colonies, he was passionately fond of horticulture, and introduced into Europe a great many tropical fruit trees. He established a fruit nursery at Equateurville, and published a number of useful notes on the alimentary plants of the Congo.

GARDENING APPOINTMENT.

Mr. A. Thompson, previously at Spring Grove Gardens, Oughtibridge, as Gardener to R. Whitehead, Esq., Hargate Hall, Millers Dale, Derbyshire.

ENQUIRY.

I should be interested to know if any of your readers have any experience of rabbits eating Ericas I am about to plant a quantity of Ericas in woodland where rabbits are plentiful and do not wish to enclose with wire netting if this is not necessary. *T. C.*

REMARKS.—More business has been done in this department during the past week; supplies have increased generally and prices have been on the downward direction. Best Daffodils are retaining their prices. The newest sorts from home-growers are Victoria and Sir Watkin; King Alfred is exceptionally fine in quality just now. Good supplies of the cheaper grades are coming from Cornwall, Guernsey and Scilly; these consist of Golden Spur, princeps and Henry Irving. The largest supplies of the season of Narcissus Soliel d'Or and Grand Primo arrived last week. Tulips still retain their excellent quality, especially the double varieties, which include Flamingo, Tea Rose, Double White, Double Yellow, Rosina and Double Pink. The first consignment of the red Darwin Tulips, Bartigon and William Pitt, came to hand last week; a few pink Darwin Tulips are also on sale. Prices of Arums (Richardias) have been greatly reduced owing to the increased quantities. Supplies of Lilium longiflorum are ample for present requirements, also of L. lancifolium rubrum. Of Roses, Columbia and Richmond are the most plentiful; these are blooms of the new crops, and their quality is improving gradually. Other subjects are similar to those listed last week, and they show little fluctuation in prices.

—Plums	5 0-8 0
—Others	4 0-5 0

REMARKS:—Trade shows an improvement generally. Large Cooking Apples are in fair demand, and best quality vegetables are a good trade.

GLASGOW.

WHILE prices of cut flowers generally moved in an upward direction, business during the past week was somewhat slow. Daily supplies were none too plentiful as local growers are expecting a better range of values in the near future. Daffodils were dearer, King Alfred being worth 2/6 per dozen; Golden Spur, 2/- to 2/8; princeps and Sir Watkin, 1/8 to 2/-; ornatus, 1/- to 1/4; Narcissi special, 3/- to 4/-, and ordinary, 1/- to 2/-. The changes recorded in quotations of Tulips were mostly towards higher levels, and the averages for the week worked out as follow:—William Pitt, 1/9 to 2/-; Bartigon, 1/6 to 2/-; Le Notre, 1/6 to 1/9; Ibis, 1/2 to 1/5; Rose Tendre and Rosina, 1/6 to 1/8; Couronne d'Or, 1/2 to 1/4; Tea Rose, 1/- to 1/3; Brilliant and Prince of Austria, 1/ to 1/2; Flamingo, 1/-; Murillo special, 11d. to 1/1, ordinary, 8d. to 10d.; La Reeve, 8d. to 1/-, and Thos. Moore, 8d. to 10d. Hyacinths of all colours ranged from 8d. to 1/- for 3's. Madame Butterfly Roses made 12/- to 14/- per dozen. Lilium longiflorum (Harrissii) was cheaper at 7/- to 9/-, but Arums kept steady at these prices. Mimosa declined to 5/- and 7/- per cane, and Carnations were easier at 3/- to 4/- per dozen. Lily-of-the-Valley sold from 1/6 to 2/- per bunch; Smilax at 1/- to 1/6, and Asparagus Fern from 6d. to 1/2. Good quality Hyacinths in bowls averaged 2/- each.

A moderate turnover was reported in the fruit market. Oranges continued to appreciate in value, Jaffas making from 17/- to 19/-, and Valencia counts were also firmer 360's and 504's commanding 9/- to 10/6, 300's 10/- to 14/-; 240's and 200's, 14/- to 16/6; 420's, 12/6 to 16/ large ditto, 18/- to 28/-; and 214's, 14/- to 18/-. Mandarin improved to 1/2, and Seville Bitter Oranges were scarce round 14/6 per half-chest. Palermo Lemons, 300's, were worth 12/6 to 15/6, and Porto Rico Grape Fruit, 22/- to 24/-. Apples were offered in great variety and prices of certain brands were 1/- down at the following quotations:—British Columbia Delicious, 13/- to 15/- per case; Spitzbergen, 11/- to 13/-; Jonathan, 10/- to 12/-; Grime's Golden, 9/- to 11/6; Oregon Newtown, 13/- to 16/-; Spitz. 10/- to 12/6; Washington Delicious, 13/6 to 16/-; Spitzbergen, 11/- to 13/-; Newtown, 16/6 to 18/-; Grime's Golden, 10/- to 12/6; Winesap, 12/- to 14/-; Virginia York Imperials, 32/- to 35/- (per barrel); Ben Davis, 12/6 to 16/-; Ganos, 16/- to 20/-; New York Greening, 26/- to 30/- (barrel); Ben Davis, 12/- to 15/-, Nova Scotia Baldwin, 10/- to 15/-; Golden Russet, 16/- to 24/-. Canadian Baldwin, 22/- to 25/- (barrel), and Greening 28/- to 32/-. South African fruits were in fair demand Peaches making from 5/6 to 7/6; Pears, 4/6 to 6/6; and Plums, 5/6 to 9/-. The price of Winter Nelis Pears was unchanged. Gros Colmar Grapes remained steady at 3/- to 3/6 for English; 1/8 to 2/6 for Dutch; and 2/6 to 3/6 for Scotch. Pines averaged 5/- each.

In the vegetable section, Sea Kale ranged from 2/3 to 2/9; Sprue, 1/- to 1/3; Endive, 3/- to 4/-; French Beans (Madeira), 4/- to 5/6; forced Lettuces, 1/6 to 1/9 out-door Lettuces, 3/6 to 4/- per dozen.

ANSWERS TO CORRESPONDENTS.

GARDENER'S NOTICE TO QUIT.—*O. G. W.* It has been held by the High Court that a head gardener is to be regarded as a domestic servant, and must give or receive a month's notice. There is no reason why an employé should not obtain another situation before giving notice provided he gives a proper notice afterwards, but should he not serve throughout the period of such notice he will be liable in damages to his employer.

MALE AND FEMALE CHRYSANTHEMUMS.—*P. Cheeseman.* All Chrysanthemums have hermaphrodite and female flowers in one bloom. A wild species has all the ray florets female. In semi-double and double cultivated Chrysanthemums the rays or outer florets are greatly multiplied, and all these are female. The centre of the flower of the wild plant consists of a great number of small yellow florets with four or five teeth to the corolla, and all these have the male and female organs present, except one here and there that may be imperfect owing to crowding. In a perfectly double flower it is difficult or impossible to find these hermaphrodite or perfect florets; but if you want to cross them or to get seeds grow some plants in pots, stop them two or three times during the season, give them no feeding but starve them in order to get an open centre or eye, when perfect florets with pollen will be found. Clip away the rays to half-an-inch or so from the base. Look for the female organs in the ray florets, namely, a very short style with two short arms at the top. In due time when the central florets come into bloom, you will be able to find the yellow pollen which may be transferred with a camel-hair brush to the central as well as the ray florets of some other variety you wish to cross. Clip away the rays of all blooms upon which you wish to operate.

NAMES OF PLANTS.—*A. P.* Fittonia Pearcei. The Cypripedium is probably a form of C. Little Gem (Baron Schröder × Harrisianum) The flower is rather larger than the original, but is similar in other respects. *H. P. W.* Probably Begonia maculata. *B. F. D.* Bignonia venusta, a native of Brazil, but introduced to many tropical and sub-tropical countries, where it is grown extensively. It is not common in this country except in botanic gardens. *L. C.* Lonicera Standishii.

William Bateson. By the death of Dr. William Bateson (as recorded in our issue of February 13) the world has lost one of its most distinguished men and the sciences which he expounded have been deprived of a great leader. His friends, and they were many, have sustained a yet severer loss. To them his friendship—a little aloof, as it must be when great men give friendship to lesser ones—was a source of inspiration. For no man knew Bateson who was not the better for knowing him. In his search for knowledge and in his love of truth there was, it is true, a certain ruthlessness which might repel those who cared for these virtues less strenuously than he did. And those who prefer the prophets to prophecy smooth things might be startled by his outspokenness. In his direct glance there were not only a grave fearlessness and a bright enthusiasm, but kindness was also there. For Bateson combined in an unique way qualities which rarely meet in men cast as he was in the heroic mould. He loved truth, but he cared also for the good things of life, pictures and books, and fun and friends. The life which he led, when—after seeking in vain the clue to the mysteries of evolution along the well-worn tracks of embryological science—he turned to the study of variation, seemed to have invested him permanently with a habit of loneliness. But it was only the loneliness of preoccupation. Pioneers must perforce be solitary. And so for many years he went his way—as though inspired by that hard saying that "science is measurement"—noting, measuring and recording the range of variation in living things. Meanwhile the biologists went on along the usual high roads of discovery, leaving Bateson straying in these neglected and tangled by-paths. But presently he came back and startled them by publishing a massive tome, *Materials for the Study of Variation*, to which he added a brilliantly written preface and in which he declared on irrefragable evidence that nature, far from jogging along the evolutionary way by imperceptible paces, is of a more joyous habit and is always apt to skip and jump. In these discontinuities of variation Bateson predicted would be found the starting points of the evolution of new species. Controversy, which now seems lifeless, but which played a vital point in the progress of biology, sprang up around these views and Bateson proved himself a bonny fighter. But though he hit hard the wounds he gave soon healed, for the weapons he used were clean. He was not one of those of whom Sir Thomas Browne speaks as not being worthy to testify to truth. Then suddenly Mendel's immortal researches were rediscovered and Bateson saw in them the clue which he had sought so long. Thenceforth throughout his life he devoted himself to the experimental study of heredity, for which with his usual felicity of expression he coined the name "genetics." Of his many discoveries there is no need to speak now in detail. but none who learned them at first hand can forget how by genetic magic he succeeded in stripping off, as it were one by one, the coats of many colours which may adorn a flower—a Sweet Pea for example—and from simple pigments compounded in the Mendelian pestle, rearranging the plant in ordered gorgeousness. Nor may it be forgotten that it was Bateson and his colleagues who first resolved the mystery of reversion by showing how two Mendelian characters, long wandering yet not lost, might chance to come together by the mating of the kinds which bore them severally and, in meeting, reproduce the character which their separation had perforce suppressed. In a masterly series of reports to the Evolution Committee of the Royal Society, and later in the *Journal of Genetics*—which he founded in collaboration with his colleague Professor Punnett—these and many other of his discoveries and those of his pupils and colleagues are recorded. Not least among the results of these unremitting labours are those which showed the curious orderliness in disorderliness which sometimes appears in Mendelian experiments which ordinarily are quite disconnected with one another, when characters get bound up or coupled together or, conversely, disjuncted or repelled from one another. And it is pleasant to know that although Bateson failed to find the deep significance of these facts he lived to learn and welcome its discovery by the brilliant band of present-day American geneticists. So in the fullness of his powers and ardour of discovery, Bateson has died and there is left only to the friends who so greatly cared for him, the knowledge which he bestowed, the inspiration which he imparted, and the memory of his rare and great personality.

Capt. F. Kingdon Ward's Ninth Expedition in Asia.—Capt. F. Kingdon Ward left London on Thursday, February 18, for Burma, whence he will commence his ninth plant-hunting expedition in Asia. He proposes to explore a practically unknown part of Tibet, and at one period of his travels expects to be entirely out of touch with civilisation for a period of three or four months. We feel sure our readers will be glad to know that Capt. Kingdon Ward has promised—as on previous occasions—to contribute an account of his travels and discoveries, in serial form, to *The Gardeners' Chronicle*.

Mr. Wm. Cuthbertson—Many of our readers will be pleased to learn that Mr. and Mrs. W. Cuthbertson, who are "going round the world," are both well and having an enjoyable and interesting time. In a letter dated January 11, Mr. Cuthbertson stated that they were going on to Sydney, from Melbourne, that night, on their way to New Zealand.

The Australian Apple Crop.—The first shipment of the new season's Australian Apples is due to arrive in London on March 25. According to the Commissioner for Australia, Sir Joseph Cook, forty-three vessels have been listed to load Australian Apples for Great Britain between now and the end of May, and it is estimated that over 2,500,000 cases will be shipped this season.

Kenwood.—Dame Beatrix Lyall, Chairman of the L.C.C. Parks Committee, planted a Beech tree in Kenwood on the 13th inst., to mark the spot where the King dedicated the use of the estate for the public last July. Dame Beatrix Lyall stated that improvements at Kenwood were shortly to be put in hand. The bathing pond was to be fitted with dressing accommodation and screened, more seats were to be provided, and a rustic shelter, to be erected out of the balance of the funds raised to acquire Kenwood, would be in readiness for the April showers. The grass tennis courts would be ready for use during the coming summer.

Wormseed.—The possibility of growing Levant Wormseed (Artemisia Cina) in certain sections of the United States as a commercial crop has been considered. This plant is the source of the important vermifuge santonin. The present source of the plant is Turkestan and Persia, and the importation of santonin has been so reduced in recent years that it commands an exceedingly high price. Artemisia Cina has been grown successfully for several years at Chico, California, which indicates that it will probably thrive in the hot interior valleys of California

The Alaska Pea.—This culinary Pea is the principal variety used in the canning industry in the United States of America because of certain peculiar characteristics which it possesses. During the past season no fewer than two-hundred-and-three samples of Alaska Pea were planted at Arlington Experiment Farm, U.S.A., these being obtained from different retail seedsmen. It is interesting to learn from the annual report issued by Mr. W. A. Taylor, Chief of Bureau, of the Department of Agriculture, U.S.A., that the different samples in the collection varied from pure Alaska variety with no mixture, to those which contained not a single plant of the Alaska variety, showing that American seedsmen are no more to be trusted than some in other countries. It is pointed out in the report that the planting of such spurious or mis-named seeds, if grown for canning purposes, will prove a serious loss to the growers. During 1924 no fewer than four hundred varieties and strains of Peas were planted in a trial plot at McMillan, Michigan, and the work of testing is being continued during the current season, the collection including several hundred newly purchased samples of Pea seeds from foreign sources. In the selection-work special attention is being given to the Alaska variety with a view to segregating particularly promising strains or types. The experience in America serves to emphasize the importance of trials of vegetables, varieties and strains of which are more often confused than in other crops. An inspection of a trial of, say, culinary Peas or Lettuces at Wisley at once proves the great duplication of names for varieties and the need for eliminating all inferior strains, some of which are so distinct as to bear little resemblance to the type.

Belgian Sweet Pea Show.—The exhibition of Sweet Peas arranged by the Belgian Sweet Pea Society is to take place in the Brussels Botanic Garden from the 26th to the 28th of June next. The Minister of Agriculture has promised his patronage, and the exhibition appears likely to be very successful. The cultivation of this flower has increased very considerably in Belgium during the past three years.

The Frankfurt Palm Garden.—The celebrated Palm Garden at Frankfurt is to undergo considerable alterations and improvements in the near future. The houses have been extensively repaired and improved, and new Rose gardens and herbaceous gardens are now being planted. The present Rose garden is old-fashioned, and the soil is "Rose-sick"; it has therefore been decided to make an entirely new Rosarium on the lawn in front of the Taunusplatz, where the Roses will be planted in beds according to colour. The herbaceous garden will be a new departure, there having been none up to the present. The Dahlia trials having proved very popular, the cultivation of this flower is also to be greatly extended, and summer-blooming kinds will be introduced; more attention is also to be paid to the pot-plants in the show houses.

Prizes for London Gardens.—*The Daily Telegraph* is again offering prizes for the best gardens in the London postal area. There are four classes, in two of which a first prize of £100, a second of £40, a third of £20, a fourth of £10 and a fifth of £5 are offered. Class three is for gardens at the front, sides or back of houses, restricted to those not exceeding one-eighth of an acre; the remaining class is for gardens of houses not exceeding a rateable value of £35 per annum, situated within a four miles' radius of Charing Cross. Full particulars of the competition may be obtained from the Gardening Editor, *Daily Telegraph*, Fleet Street, London, E.C.4.

Excursion to the Scilly Isles at Easter.—The Garden Club, Limited, is arranging for members and their friends to visit the Scilly Isles at Easter for the purpose of inspecting the bulb fields and gardens. The party, which will be conducted by Mr. Herbert Cowley, will leave Paddington on Thursday night, April 1, and embark at Penzance for the Scilly Isles on the morning of April 2, returning on Tuesday, April 6, or on the morning of April 7. The cost of the trip, including first-class travel and hotel, together with visits to gardens, will be about £13. Special arrangements may be made beforehand for those desiring to stay longer.

Aphides Infesting Bulbs in Store.—Although the fact is not new to science, few horticulturists are aware that—under certain conditions—colonies of aphides are present under the outer skin of bulbs and corms. At lifting time the bulbs may appear to be free from infestation, but if the pest is present it may multiply amazingly while the bulbs are in storage, with the result that the "flesh" of the bulbs becomes pitted, soft, and discoloured. When these colonies occur there is the still greater danger of further infection so soon as the bulb begins to grow and the apex of the growth commences to open. The aphis chiefly responsible for this infestation is Anuraphis tulipae, although Rhopalosiphonius tulipaella has also been found. Special attention has been drawn to the trouble that may arise from the presence of these aphides by the destruction by colonial authorities of a valuable consignment of bulbs and rhizomes exported from this country because they were infested with aphides and mites, although they appeared perfectly clean when dispatched. Investigations made at the Ministry of Agriculture's Plant Pathological Laboratory at Harpenden have shown that the infestation could not have been discovered, before packing, except by a process which would have involved the destruction of the bulbs examined. The development of the infestation occurred between the despatch and the receipt of the consignment. Further investigations and experiments at Harpenden* have resulted in the discovery of a method of fumigation which will destroy the aphides without damaging the bulbs, except in the case of Iris filifolia and giant Iris Xiphium, although these specimens were in such poor condition (their planting season being long past) that they may have suffered as a consequence of weakness. The method which has, so far, given the best results is fumigation with paradichlorbenzene. A close fitting box is used as a fumigating chamber, and in the bottom of this is placed a layer of crystals of paradichlorbenzene; the crystals are covered with a single thickness of loose-textured sacking on which the bulbs to be exported are laid and, in turn, covered with a similar piece of sacking on which a second layer of crystals is placed. The box is then closed tightly and left closed for not less than forty-eight hours, preferably for three days. This lengthy period of fumigation appears necessary because during that period any moulting aphides become subject to the treatment which would be ineffective in, say, forty-eight hours, owing to the natural protection the pests possess when about to change their skin. The experiments suggest that the lesser period of fumigation might be effective if the bulbs were treated soon after they were lifted. Further experiments are in progress, especially with a view to obtaining a cheaper and equally effective fumigant.

THE LATE DR. WILLIAM BATESON, F.R.S.

New Immune Varieties of Potatos.—The Minister of Agriculture and Fisheries has approved as immune from Wart Disease of Potatos for the purposes of the Wart Disease of Potatos Order of 1923 the following additional varieties of Potatos: Celurca; Dunaverney; Grannispud; The Mac; Main's Triumph; Response; and Wonderful.

The Jamaica Banana Industry.—The cultivation of the Banana is one of the chief industries of Jamaica, but according to the somewhat belated report of the Jamaican Department of Science and Agriculture for 1924, the 1924 crop suffered a loss in value, as compared with the previous year, of £1,040,000. The number of stems was 12,000,000, which was some 483,000 stems short of the previous year. The report states that the effect of a loss of 25 per cent. in the value of exported Bananas has naturally reacted on trade and finally on public revenues. Jamaican growers have suffered three bad seasons through drought, and in addition the markets for Bananas have been bad. The significant statement is made that "the slow but generalised paralysis resulting from a three years' drought is even more deadly to the agricultural success of the colony than the swift destruction wrought by a passing cyclone." It is pleasing to know that the prospects of the Banana industry for the coming season are excellent.

Kew Bulletin.—No. 1, 1926, of the *Bulletin of Miscellaneous Information*, published by the Royal Botanic Gardens, Kew, appears in a new cover and includes a coloured plate which is, we believe, a new feature. The plate illustrates an article on "Taxonomic and Genetical Notes on Some species of Nemophila" by R. J. Chittenden and W. B. Turrill. The number also contains particulars of the Gamble herbarium which was presented by the late Mr. J. S. Gamble to Kew, who also presented to Kew his very valuable and interesting collection of hand specimens of Indian Timbers, which have been placed in No. 4 Museum. Amongst other articles the more important are "Humboldt and Bonpland's Itinerary in Colombia"; "Additions to the *Index Kewensis*"; and "Linden and Planchon's Plantae Columbianae."

The proposed Scottish Farm College.—At a meeting of the Governors of the West of Scotland Agricultural College, held at Glasgow last week, the offer of Mr. John Hannah, Girvan Mains, to present the mansion house and policies of Auchencruive Estate together with an area of three hundred acres of arable land was rejected by seventeen votes to nine. In the course of discussion, opposition was directed against the condition stipulating the removal of the college from Glasgow, owing to the location being too far away from the area which the college served, and also on account of the expense necessary in structural alterations and removal. In a letter to the press on the day following the meeting, Mr. Hannah explained why he insisted on the removal of the college from Glasgow to the Dairy School from Kilmarnock. He pointed out that large sums were being annually expended on agricultural education, and yet farmers were not being educated. There were approximately 9,200 farms in the area served by the college, and assuming the average tenure of each holder to be thirty-five years, 260 farmers enter or succeed to the tenancy each year. During the last five years the average number of students enrolled for the first year's course for farmers was twenty-two, and of the seventy-four students who enrolled for the three years' course during the same period, only nineteen came from farms. That is to say, seventy-five per cent. of the students came from the city and neighbourhood and were taking the course not because they had any special interest in agriculture but to acquire knowledge in botany, chemistry and poultry-keeping for commercial and other purposes. As showing the fallacy of continuing the college on its present lines, he quoted a letter from a farmer in Galloway stating that so far as that area was concerned the college was a dead letter.

Losses on Small Holdings.—Mr. Guinness, in reply to a question in the House of Commons, stated that in the financial year ended March 31, 1925, the claims in respect of losses incurred by County Councils in England and Wales in respect to small holdings amounted to £791,850. Similar claims will be made in respect of the year ended March 31, 1926, but thereafter the Ministry's payments will cease to be made on the basis of annual losses, but will be determined by the result of the valuation now in progress under the Land Settlement (Facilities) Amendment Act, 1925.

Town Botany in Winter.—In the botany section of Glasgow University, on Saturday last, Professor J. Montagu Drummond, delivered the second of a series of lectures under the auspices of the Workers' Education Association. Taking "Bulbs" as the subject, he described the distinctive features of bulbs, corms, rhizomes and tubers and their structure. Using the Onion, Tulip, Crocus, Cyclamen, Gloxinia, Iris, Artichoke, Potato and Dahlia for demon-

---

*The Control of Aphides Infesting Bulbs in Store. R. Stenton, *Journal of the Ministry of Agriculture*, Vol. XXXII, No. 11.

stration purposes. Referring to the influence of light and heat in the formation of root growth as practised in the cultivation of bulbs, in bowls of fibre in the dark, he did not go so far as to say that light had nothing to do with it, but it was not of so much importance as keeping the plants cool. In the ordinary dwelling-house the coolest place was generally a dark place, and it was more a question of keeping the bulbs in a low temperature to allow roots to develop. The difference between a rhizome and a corm was simply a question of degree, and the Iris and Solomon's Seal were used as examples of the system by which the growth of each successive year could be traced by means of the scars. The distinctive character of multiplication was indicated in the tubers of the Potato and Dahlia which on separation produced a number of plants, and attention was also drawn to the close resemblance between the structure of a Narcissus bulb and that of a Brussels Sprout. The important function of the leaves of bulbous plants was commented on, and as one year's leaves were the basis of a new bulb and new flower they should not be removed, inasmuch as they provided the food materials.

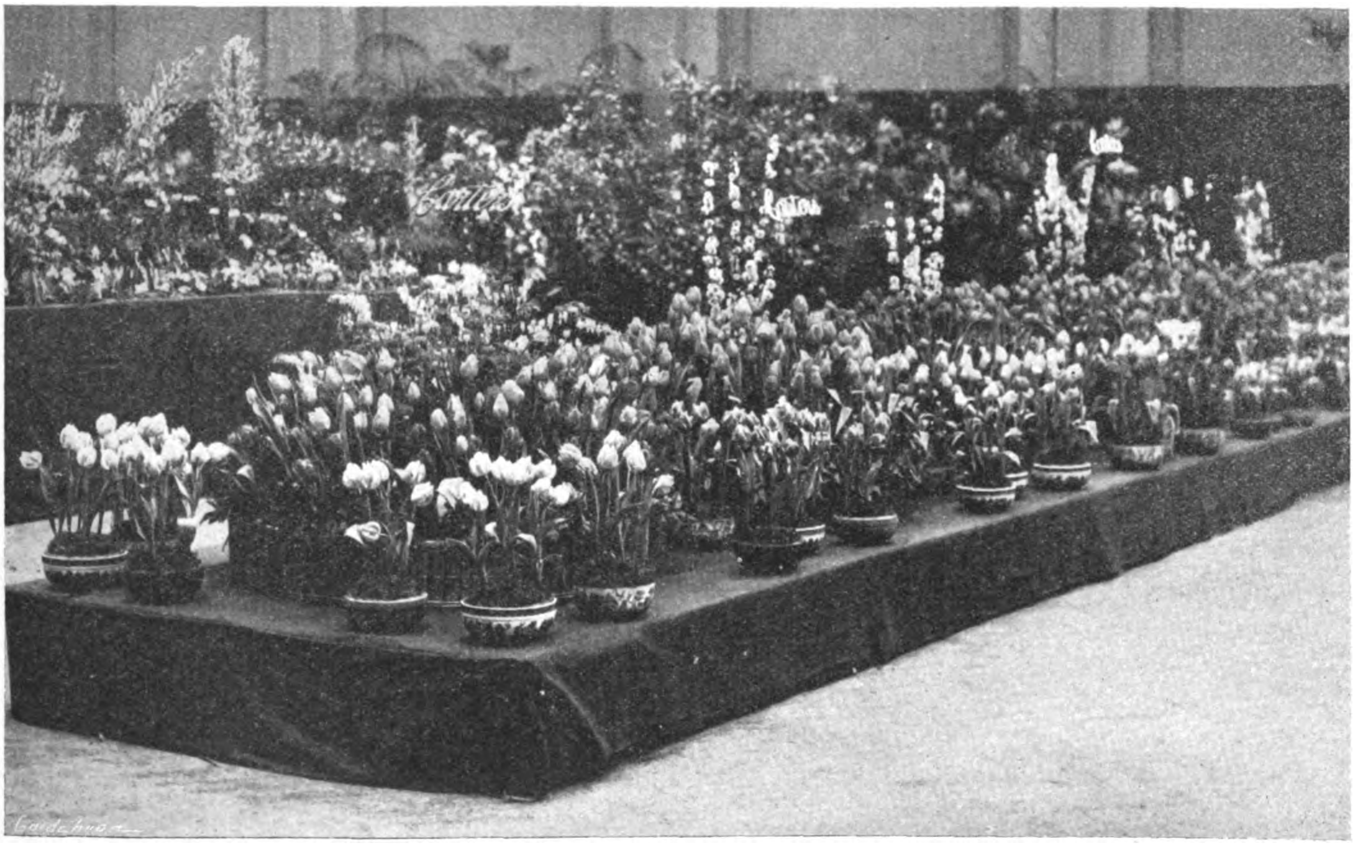

FIG. 63.—MESSRS. J. CARTER & CO.'S EXHIBIT OF TULIPS AT THE ROYAL HORTICULTURAL HALL ON FEBRUARY 9.
(see p. 124.)

Imperial College of Tropical Agriculture.—In reply to a question in the House of Commons, Major Hennessy stated that the Government had decided to make a capital contribution of £15,000 towards the cost of the erection of a hostel, a contribution of £3,000 towards the general expenses of the College in 1926-7, and, if absolutely necessary, certain further contributions in the three following years.

Royal Horticultural Society's Amateurs' Show.—We regret that in our issue of February 6, p 91, we gave the date of the Royal Horticultural Society's Amateur Exhibition as July 22, whereas the date of the show is June 22.

Agricultural and Horticultural Education in Algeria.—The French journal, *Jardinage*, for February, contains a very interesting article from the pen of M. G. Truffaut on the subject of agricultural and horticultural education and research in Algeria, which has made rapid strides in the last few years under the auspices of the French colonial administration. Education is of importance owing partly to the difficulty of obtaining properly trained and qualified labour on the land, and it was to provide it that the College at Maison-Carrée, near Algiers, was founded in 1905. The college has wide domains, and offers extended facilities for study and research in many different directions. It has developed considerably in recent years, and other smaller colleges have been established, as well as a number of research stations each devoted to one kind of cultivation—Cotton, fruit-growing, sheep-farming, cereals suited to dry climates, Grapes, etc. Tobacco growing has received much attention in the last few years, and it is claimed that certain Algerian Tobaccos yield little in quality to the best Egyptian kinds. An interesting feature is the insectarium attached to one of the trial grounds, where insects are reared which are parasitic on certain plant pests. Vine-growing is another subject which is being studied carefully, and which has already yielded encouraging results. In the favoured Mascara region excellent Grapes are produced suitable for almost every purpose, including the making of liqueurs. Sugar Beet cultivation has been tried for the past ten years, and the results tend to show that the quality and sugar content of the Beets exceed those produced in the north of France.

Appointments for the Ensuing Week.—Tuesday February 23: Royal Horticultural Society's Committees meet; Newcastle Horticultural Mutual Improvement Society's meeting and lecture. Wednesday, February 24: Wimbledon Gardeners' Society's meeting. Thursday, February 25: Paisley Florists' Society's meeting. Friday, February 26: Association of Economic Biologists meeting. Saturday, February 27: Lancaster and District Horticultural Association's meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Horticultural Society.* In anticipation of the coming Industrial Exhibition, the Council of the Horticultural Society has decided upon some new regulations, which it is now time to make public. In the first place, each Fellow of the Society may have forty-eight privileged tickets instead of twenty-four, as heretofore. It is also settled that all Fellows shall have an early admission at twelve o'clock, together with one friend; and that the same privilege shall be extended to the wife or sister of a Fellow; he not being able himself to attend. And in order to make this regulation the more valuable, the public will not be admitted till two o'clock instead of one, as in former years. At the same time the admission fee payable on the election of a Fellow is reduced from six guineas to two guineas. Mr. Hosea Waterer, of Knap-hill, who has withdrawn from the Royal Botanic Society's exhibitions in the Regent's Park, has also made arrangements for displaying his magnificent American plants in a part of the garden recently prepared for the purpose. Admission to this exhibition will be by tickets, 1/- each; but Fellows are personally exempt from that charge. Finally, it is intended to authorise all foreign ambassadors, ministers, or consuls-general to obtain tickets for the strangers belonging to the nation they represent, without the formalities formerly insisted upon in such cases. By these arrangements the privileges of Fellows are very substantially enlarged, and at the same time the utility of the Society will be much increased. *Gard. Chron., February 22, 1851.*

The Week's Work.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Increase of Growth.—As the present month advances the daily amount of sunlight and sunshine will increase appreciably, and most Orchids will begin to show renewed activities. But they should in no way be hastened into growth by an increase of moisture or fire-heat, as it is advisable to keep them at rest so long as possible. Bursts of sunshine during the middle of the day will raise the temperature of the various divisions, and considerable attention must be given to ventilation, for it is essential that a constant supply of fresh air be admitted without causing excessive fluctuations of the internal temperature.

Re-potting Masdevallias.—The general re-potting of Orchids usually commences about this period, and among the many that may claim attention in this respect are the Masdevallias. One of the favourite species of this genus is the pure white M. tovarensis. After the flowers have faded and the plants have started into growth afresh is a suitable time for re-potting or breaking up overgrown specimens and such as have become bare of leaves towards the centres. Orchid pans of medium depth with holes for suspending are suitable receptacles. These should be well-drained. A mixture of equal parts of Osmunda-fibre and Sphagnum-moss, cut into short portions, with a fair sprinkling of half-decayed Oak leaves, rubbed through a half-inch sieve, is a suitable compost for Masdevallias. The strong-growing species, such as M. ignea, M. Harryana, M. Veitchiana, and others of this section, may be grown in ordinary flower pots. The members of what is known as the Chimaera section are best cultivated in Teak-wood baskets, as their flowers are produced in a downward direction, and no crocks should be used in the drainage. The cultural requirements are much the same as for Odontoglossums, but Masdevallias should never be allowed to suffer from dryness at the roots. The plants should be watered with care for a time after root disturbance, but when well-established, they delight in copious overhead waterings, which are helpful in warding off attacks of red spider, to which the leaves of Masdevallias are extremely subject.

FRUIT UNDER GLASS.

By T. PATEMAN, Gardener to SIR CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Melons.—Plants raised from seeds sown as advised in a previous calendar are ready for planting out. Although the weather of late has been fairly mild, it has been practically sunless, and the young plants are consequently a little on the weak side. If the plants are not satisfactory it will be well to sow again, but those that have good, healthy stock should prepare a suitable bed in which to plant them. It is desirable to have bottom heat for this early crop, and even where it is supplied by fire-heat I would strongly advise a bottom heat combined with a bed of horse manure and leaves. The material for making the hot bed should be prepared in readiness out-of-doors, and should consist of equal parts of litter and leaves well mixed together. Throw the leaves and dung into a high heap and turn the latter about twice to allow the rank gases to escape before making up the bed. In the meantime the house or pit in which the Melons are to be grown should be thoroughly cleansed, washing the glass both inside and out so as to obtain the maximum amount of light. Melons grown on the cordon system will only need to be planted from fifteen inches to twenty inches asunder, therefore, in preparing the bed it will be necessary to cover a space two feet in width and about six inches deep with the compost, which should consist chiefly of good sweet loam, mixed with old mortar rubble and bone-meal. Make the soil moderately firm arranging a small mound of it for each plant. This will allow for a surface dressing when the border is well filled with roots, to assist the plants when they are swelling their fruits. Maintain a humid atmosphere by lightly syringing the plants and the bare spaces, but the grower must be guided in this by outside conditions. The night temperature should range between 65° and 70°, with a substantial rise during the day with sun-heat. Make another sowing in small pots to have young plants in readiness to meet the requirements of the establishment.

Cucumbers.—Plants raised from seeds sown during the first week in January are ready for planting out. See that the house in which they are to be grown is thoroughly cleansed for this early crop. I strongly advise the use of bottom heat from a bed of litter and leaves as advised for Melons. Cucumbers may be planted out four feet apart on small mounds of soil composed of two parts loam, one part short horse manure and one of leaf-mould. Create a humid atmosphere in the house and maintain the same temperature as advised for Melons.

Grapes in Store.—Give attention frequently to Grapes in store, seeing that no decayed berries are allowed to remain even for one day. A temperature of 45° is suitable, provided the atmosphere is kept dry. Late Grapes will not keep in an ordinary fruit room where Apples are stored.

PLANTS UNDER GLASS.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

Asclepias curassavica.—This useful greenhouse plant may be raised from seed sown at this time, the seeds germinating readily in a temperature of 55° to 60°. When fit to handle, the seedlings may be pricked off into small sixty-sized pots, placing three or four plants in a pot. In due course they should be potted on intact into five-inch pots, in which receptacles they should flower towards the end of the summer, at which time they prove useful for the greenhouse, when choice flowering plants for conservatory decoration are scarce. Athough generally treated as an annual, this plant may be grown a second year. These old plants should be wintered in a greenhouse, keeping them on the dry side. Early in the year when young growth develops from the base, the old shoots should be cut down and the plants transferred to six-inch or seven-inch pots, in which they should give a good display during the summer. This plant grows freely in any good potting compost, and succeeds in an ordinary greenhouse.

Rhododendrons.—The tender Rhododendrons of the R. javanicum and R. jasminiflorum types, of which there are many fine varieties, are deserving of much more general cultivation, for with a good collection they may be had in flower, more or less, all the year round. The successful cultivation of these plants is by no means so difficult as is generally imagined, and most of them succeed in a much lower temperature than that generally accorded them. In fact, some of the stronger-growing varieties succeed perfectly in an ordinary greenhouse in which the temperature during winter often falls to 45°; in such houses they make fine specimens planted out in a well-drained, shallow bed. They are easily propagated at almost any time from internodal cuttings made of shoots that have just finished growing, but it is usual to sever the shoots below a whorl of leaves. After trimming off the foliage, they should be inserted singly in small pots containing fine, sandy peat. After watering the soil the pots should be plunged in a warm propagating case provided with a bottom heat of about 70°. When rooted the plants should be stood out on the stage near to the roof-glass. As they grow and are potted on they should be gradually accustomed to an average temperature of about 55°. The potting compost should consist of a mixture of good fibrous peat and sand, with just a sprinkling of light loam for the stronger-growing varieties. Free drainage and careful watering are essential details of cultivation at all times. These Rhododendrons may be flowered in forty-eight-sized pots, but where large specimens are required, they should be transferred to larger receptacles. always, however, taking care not to over pot them. It is urged against them that they make straggly, unsightly plants, and this is true to a certain extent, but this may be largely obviated by bending down the shoots and training them around stakes. This treatment has the tendency to make them break from the older wood. A few good varieties are Taylori, Princess Royal, Latona, Diadem, King Edward VII, Cloth of Gold, Mrs. Neal and Lord Wolseley.

THE KITCHEN GARDEN.

By F. STREETER, late Gardener to MAJOR ALBERT PAM. Wormley Bury, Broxbourne.

Cucumbers.—With the aid of a good hot-bed and a fair amount of fire-heat. Cucumbers may now be raised from seeds. The hot-bed should be made in a low, span-roofed house; in making the hot-bed use three parts leaves to one part of long litter and turn the materials about three times to sweeten them. Cover the bed with a mixture of three parts turfy loam to one part decayed leaf-soil, and sufficient sand or road grit to keep the compost open. Arrange the soil in mounds four feet apart along the bed. and when it is thoroughly warmed through set out the plants from five-inch and six-inch pots. Grown on briskly and in a moist, hot atmosphere, the plants will make headway quickly. Do not stop the shoots until they have grown three parts up the house. The night temperature should not fall below 65°, and on warm, bright days admit a little air through the top ventilators when the thermometer reaches 80°, closing them again at 1 p.m.

Tomatos.—Young plants raised earlier in the season are ready for transference to six-inch pots. Use a rather stronger compost than before, consisting of three parts fibrous loam, one part finely-sifted old Mushroom-bed manure and sufficient sand to render the soil open; a dash of soot will also prove beneficial. Thoroughly crock the pots, and place the soil in the house in which the plants are growing, as it is most important that the latter should not be brought into the open air, no matter how mild the weather. Pot firmly and place a small stake to each plant. The plants will soon develop plenty of roots, and preparations should be made for re-potting them finally in a few weeks. Grow them in a temperature of about 60°, admitting air on all favourable occasions through the top ventilators.

Onions.—So soon as the weather and condition of the ground permit gently prick over the ground on which Onion seed is to be sown and make sure that it is in the best possible condition before sowing the seeds.

HARDY FRUIT GARDEN.

By W. AUTON, Gardener to VISCOUNT ELVEDEN, Pyrford Court, Woking, Surrey.

Small fruits.—If such fruits as Loganberries, Blackberries, Wineberries and other similar fruits of the rambling class have not yet been pruned they should be attended to so soon as possible. The operation consists chiefly in cutting out entirely those growths which have borne fruit, and training in shoots made in the last season of growth to take their places. These fruits may still be planted if desired; they are most useful subjects for covering the sides of old buildings or for creating quickly a screen to blot out any undesirable building, and the return of fruit over quite a long period of the year well repays any attention given to them. During the next week or two, autumn-fruiting Raspberries should be cut to within a few inches of the ground. This section of Raspberries is very useful amongst small fruits and provides dishes of berries which are much appreciated in late summer when variety in fruits is somewhat restricted. There is still time to make new plantations, but this should be done immediately and the canes cut down after planting. A good mulch of partially-decayed manure is of great benefit to newly-made Raspberry plantations.

Planting.—Weather conditions during a considerable portion of the month of January were certainly not helpful in enabling arrears of planting to be overtaken, but with better conditions prevailing, such work should be completed so soon as possible. All trees planted early in the season should be examined, and if they have become loose in the soil this should be rectified.

Strawberries.—Clean the beds, lightly fork the ground between the rows of plants, and where the latter have become loosened through frost and thaw tread them firmly into position. Maiden plants which are being grown for the provision of further stock, may be given a dressing of bone-meal, and the surface soil should be stirred frequently. Fruiting plantations may receive in addition a mulch of fairly fresh manure which, if of the right nature, will serve the double purpose of nourishing the plants during the next few months, and when washed clean by subsequent rains leaving a bedding to prevent the splashing of the ripening fruit.

THE FLOWER GARDEN.

By F. C. PUDDLE, Gardener to LORD ABERCONWAY,
Bodnant Taly-Cafn, North Wales.

Colour Schemes.—A combination of red, orange and yellow plants makes a very striking border which will be at its best during August and September. Dahlias, Kniphofias, Heleniums, Penstemons, Phloxes and Montbretias are the principal subjects that should be used. If Oriental Poppies are planted for early effect, they should be interplanted with scarlet Gladioli. Another attractive border may be composed of pink and salmon shades: this border provides a place for Paeonies in addition to pink varieties of the species already mentioned, whilst Dianthus Allwoodii is very effective as an edging. If the borders are limited to three, white flowers may be combined with the pink, but if a fourth border is available it is better to reserve the white kinds for this. The white border is most effective if it can be arranged with a green background of shrubs and in a semi-shaded position. The introduction of a few plants of pale yellow colour makes a delightful blend, and relieves the dead whiteness. If, however, the border is in the sun, a richer contrasting colour is better, and nothing is more effective than the rich crimson-purple of Dahlia Mevrouw Wurfbain and Gladiolus Master Wietse, also purple East Lothian Stocks. Borders arranged on these lines not only add to the interest of the garden, but they make a pleasant appeal to the senses, for the "blue border" has a soothingly cool effect in hot weather, the "red and orange" border has a cheering influence on a dull day, while the "pink" border is the border of early evening, and "white" is the garden of twilight.

Grafting Rhododendrons.—Layering is undoubtedly the best method of increasing choice hybrid Rhododendrons, but it frequently happens that a valuable variety has no branches sufficiently near to the ground for propagation by this method, and grafting is then the only alternative. Preparations should now be made to prepare the stocks for grafting next month. Seedlings of Rhododendron ponticum with stems about a quarter-of-an-inch in diameter should be selected and placed in five-inch pots. This is better done in early autumn, and the pots plunged out-doors for the winter. If, however, it has been delayed, the stocks should be potted with as little disturbance of the roots as possible. A frame should be prepared with a mild hot-bed and the pots plunged in this. Every effort should be made to get the stocks thoroughly established and the sap running freely before grafting takes place. Saddle grafting is the best system for Rhododendrons, and care should be taken that both stock and scion are as nearly as possible the same thickness so that a perfect union of stock and scion is ensured. The cut parts should be bound with raffia, but neither clay nor grafting wax should be used, for in the case of Rhododendrons this is detrimental to fusion of the graft and stock. After the operation is completed the pots should be again plunged in the hot-bed and the frame kept close until the union is complete, when the plants may be accustomed gradually to more airy conditions.

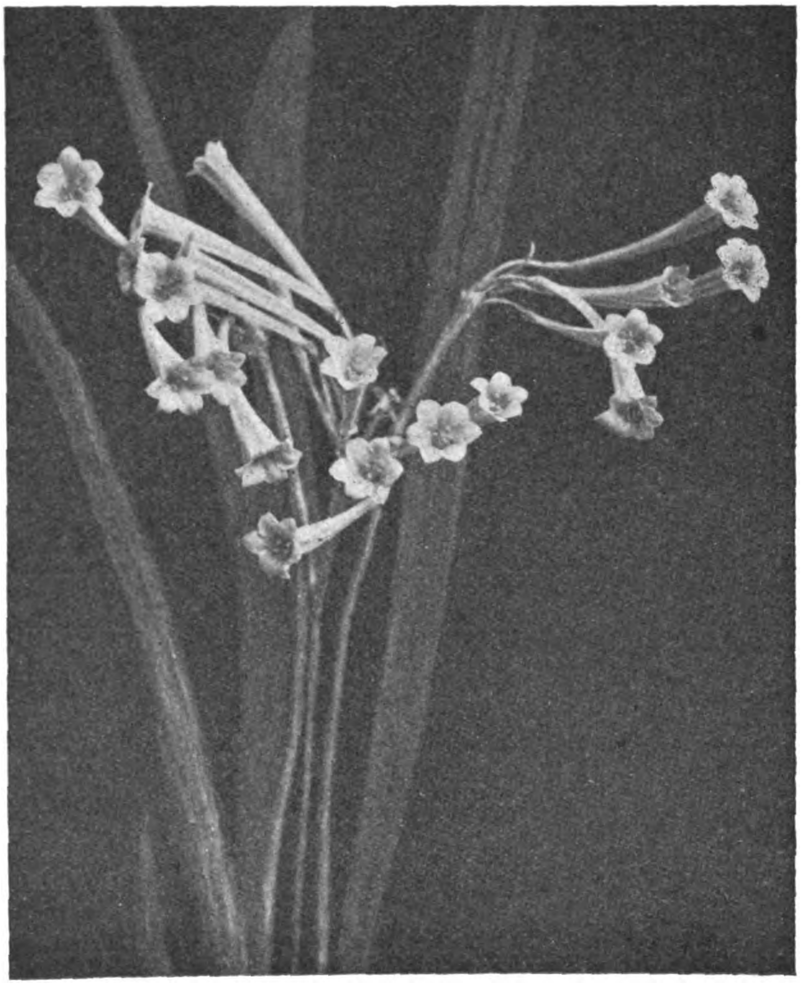

FIG. 64.—CYRTANTHUS LUTESCENS.

R.H.S. Award of Merit, February 9. Flowers tubular, yellow.
Shown by Mrs. Frank Platt-Barlow, Hans Place, W. (see p. 123).

FOR NORTHERN GARDENERS.

By A. T. HARRISON, Gardener to the MARQUIS OF AILSA, Culzean Castle, Maybole, Ayrshire.

Horse Radish.—If a new bed of Horse Radish is desired, the present is a suitable time for breaking up a portion of the old bed, and selecting sufficient crowns with a few inches of root attached, for planting. The thongs should be dibbled deeply in rows, on ground that has been well-manured and dug deeply.

Perpetual Carnations.—Cuttings of these Carnations inserted early in January should be ready for potting separately into thumb pots. Erect a temporary potting bench in the propagating house, and prepare the compost, which may consist of a mixture of loam, leaf-mould and plenty of sand. A number of small pots should also be prepared ready for use. These preparations will not only speed up the actual operation of potting, but by keeping the young plants in an equable temperature all the time, prevent any check at this early stage of their development. Pot moderately firmly, and keep the house fairly close for a few days, gradually admitting more air as the plants show signs of new growth, when in course of time they may be removed to cooler quarters.

Jerusalem Artichokes.—Where the bulk of last year's crop has been left in the ground for use as required, the roots should now be lifted and stored in some convenient spot, behind a north wall for preference, as in this position the tubers keep longer dormant and consequently longer fit for use. In lifting the crop, select medium-sized tubers from prolific stools for replanting, and if the ground is in a workable condition the planting may be done forthwith, placing the sets fifteen inches apart in the rows, and allowing a space of thirty inches between the rows.

Humea elegans.—Plants of Humea elegans which have been wintered in five-inch pots should now be shifted into seven-inch pots. This ornamental biennial is again coming into favour, and well-grown specimens are useful either for the greenhouse or for setting in odd corners in the mansion, where they will remain attractive for a long time if carefully attended to and not overwatered. They may also be used with good effect in a scheme of sub-tropical bedding, where their graceful, feathery plumes and their pleasing perfume add considerable charm. Add a quantity of broken mortar or lime-rubble to the ordinary compost, and do not give the plants too much water until the roots have again reached the sides of the new receptacle.

ORCHID NOTES AND GLEANINGS.

DENDROBIUM GATTON MONARCH.

The particularly fine form of Dendrobium Gatton Monarch, illustrated in the Supplementary Plate which accompanies this issue, was raised by Fred. J. Hanbury, Esq., at Brockhurst, East Grinstead, and it has now received the varietal name of "F. J. Hanbury." The parents of D. Gatton Monarch are D. Lady Colman and D. nobile nobilius, but Mr. Hanbury suspects that the original cross was made by using the form of D. nobile nobilius found in most collections and known as James' variety, whereas the form he used in the production of D. Gatton Monarch var. F. J. Hanbury is named "A. A. Pearson." He obtained a plant of the last at an auction sale a long while ago, and has no knowledge of the "A. A. Pearson" thus commemorated. This fine variety has bold flowers of intensely deep colouring and has been found to produce better results, as a parent, at Brockhurst, than the more commonly-grown form of D. n. nobilius.

Mr. Hanbury was fortunate in being able to raise a fine batch of seedlings of his variety of D. Gatton Monarch, all of which are of robust growth, some of the pseudo-bulbs being a yard high. The flowers of this splendid Orchid are about four inches across (one sent us is four-and-a-half inches across the spread of the petals), and have many of the fine characters of D. n. nobilis, the purple shading being deepest at the ends of the wide petals and on the sepals, The round lip has a deep rose-purple apex. then comes a creamy-white border which entirely surrounds the central rounded area of intense purplish-crimson of velvety texture, and extends to the base of the lip.

ODONTOGLOSSUM KRAMERI.

A **two-flowered** inflorescence of this extremely rare species from Costa Rica is sent by J. McCartney, Esq., Hey House, Tonge Moor Road, Bolton, who is the fortunate possessor of seven specimens of it, which flower irregularly, the curved spikes bearing from two to five flowers, each one-and-a-half inch across. The flowers are pale rosy-mauve, shading to white at the margins.

The lip has two bright yellow calli, the ovate blade having purplish lines at the base. The species is distinct in every respect from others of the genus. The original importers, Messrs. James Veitch and Sons, received a First-Class Certificate for it in 1868. A grand spike of a very fine form of O. Uro-Skinneri is also sent, showing the result of good cultivation.

ODONTOGLOSSUM KRAMERI ALBUM.

Messrs. A. J. Keeling and Sons, Westgate Hill, Bradford, send sprays of flowers, pseudo-bulbs and leaf of a very remarkable Odontoglossum received by them from Mr. C. H. Lankester, of Cartage, Costa Rica, under the above name.

The pseudo-bulbs and the nine-inch long, oblong, lanceolate leaf, are of typical O. Krameri, but the erect, one to three-flowered spikes show differences which would warrant a more critical examination when the plant flowers again, to determine whether it is a new species or not.

The flowers are pure white and very fragrant; the lip is more oblong than in typical O. Krameri, and has, especially in the form of the yellow crest, a resemblance to O. Oerstedii, which is, however, very different in growth. The question of hybridity between the two species might also be considered. Both plants are from Costa Rica. *J. O'B.*

NEW HYBRID ORCHIDS.

INDOOR PLANTS.

BROWALLIA.

Browallia viscosa is one of the strongest-growing of the annual species, and is very useful for conservatory decoration. By successional sowings the plant may be had in flower, more or less, all the year round. Seeds may be sown at the present time in a warm house, and when large enough to handle, the seedlings should be placed singly in small pots, repotting them as they require more room, until they are in six-inch pots, in which size fine specimens may be flowered. The young plants should be pinched several times to promote a bushy habit.

This plant grows well in any good potting compost and in a temperature of about 50°.

Browallia elata, and its white variety, as well as B. grandiflora are useful for greenhouse decoration. They grow well under the treatment recommended for B. viscosa.

Browallia speciosa major is the largest flowered kind, but its successful cultivation is by no means so easy as in the case of the other species. It is slower-growing, and should be grown in a slightly higher temperature, viz. about 55° to 60°. To obtain well-furnished plants it is necessary to pinch them several times. Over-potting should be guarded against; excellent specimens may be grown in forty-eight-sized pots. If desired, this species may be propagated readily by means of cuttings. There is a white-flowered variety, but from the decorative stand-point it does not compare with the blue-flowered type. *J. Coutts.*

PYCHNOSTACHYS DAWEI.

This recently introduced Labiate has already established itself as a valuable winter-flowering subject, and where blue flowering plants are in demand it seems likely to become a rival to the hitherto indispensable Coleus thrysoideus, particularly in establishments where growing accommodation is restricted. It is admitted that well-grown specimens of the latter are difficult to equal as blue-flowering winter plants, and for spectacular effect Pychnostachys Dawei cannot approach it, but the newer plant has some attributes which make it more valuable to the grower with little accommodation.

The great beauty of Coleus thyrsoideus is of comparatively short duration; it is somewhat exacting in its needs and not infrequently fails to give of its best, whilst it also needs fairly warm treatment during its whole season of growth.

Pychnostachys Dawei is a plant of the easiest possible cultivation, and its rich, linear-lanceolate leaves, borne in opposite pairs give it a furnished appearance. The flowers, disposed in whorls on a dense terminal spike, are of a rich, Gentian blue, and the whorls open in succession from the base upwards to the point thus giving a long period of display. Besides being of value for conservatory decoration it is useful for cut flower purposes, and in this direction it may be noted that after the terminal inflorescences have been cut, the lower axillary buds develop quickly and produce a secondary crop of smaller inflorescences which are invaluable for table decoration.

Cuttings rooted in the spring may be grown into specimens four or five feet high by the end of the season. The plant flourishes in an unheated pit, or will even succeed in the open from June to September. It is also just as easily raised and grown from seeds. Like all quick-growing plants, it is a gross feeder and should be given liberal treatment. *W. Auton.*

WINTER-FLOWERING PELARGONIUMS.

Where these useful greenhouse plants are grown, cuttings should be taken this month. Fill a number of five-inch pots with sweet loam of a sandy nature, and insert the cuttings around the edges of the pots; where large quantities of plants are required shallow boxes will answer the same purpose. Dust the surface of the pots or boxes with sand and soak the soil with water. After the soil has drained, place the pots on a shelf in a greenhouse where a temperature of about 65° to 70° is maintained.

Shade the cuttings from bright sun light when necessary

In about three or four weeks the cuttings will have rooted, and should be potted singly in three-inch pots The compost for this potting should consist of two parts fibrous loam, one part leaf-soil, half-part air-slaked lime and a little coarse sand. Pot moderately firmly and replace the plants as near to the roof glass as possible, to prevent damping, and to cause them to grow sturdily

As the plants make growth they should be pinched to promote a dwarf habit and to induce them to make side-shoots. Towards the end of April they will be ready for shifting into five-inch pots, using similar compost as before. Harden them in a frame, and until they are rooted only water them sufficiently to moisten the surface. Admit air gradually and increase the amount of air in the daytime as required. In about four or five weeks time the plants will be ready for their final potting in six-inch or seven-inch pots, furnished with plenty of drainage material. The compost should be made up as follows : two parts fibrous loam, one part leaf-soil, one part old Mushroom-bed manure, one part sand, half-part air-slaked lime and a good dusting of basic slag. Pot firmly. When the plants have restarted into growth give them plenty of air and grow them in a sunny position. Judicious pinching should be observed from time to time to promote sturdy growth, and care should be taken that the soil is not saturated with water. In dry weather a weak application of liquid manure or soot water, given at intervals, will be beneficial. By the middle of September the plants should be removed to their flowering quarters in a greenhouse, when they will soon develop flower trusses. *G. Barton.*

HARDY FLOWER BORDER.

NEMOPHILA INSIGNIS.

It would be a difficult task to find a more familiar garden flower than the blue Nemophila, for it is one of the first favourites of the amateur gardener, and never ceases, as some first favourites do, to retain a hold on the affections of all who grow it.

The plant is one of a series of hardy annuals obtained from California in the early days of exploration in the " Far West," by David Douglas, who was sent out by the Horticultural Society of London to secure new floral treasures for British gardens.

The Nemophilas, like the Eschscholzias, Gilias, Collinsias and other Californian annuals, make finer growth and flower more abundantly when sown in autumn than when sown in spring. The best method is to sow in August or September on poor, well-drained soil. If the plants are not too thick in the beds they will pass through the winter with but little harm, but if crowded or damp the winter weather will seriously reduce their numbers. Early in the spring they may be lifted in patches and carefully transplanted to well prepared beds.

The flowering of the plants under such treatment will surprise those who know them only as sown in spring and left in crowds to struggle for light and air. But success with spring-sown annuals may be obtained by sowing in February and March in well-prepared soil and taking special care to thin the plants so that every one has ample room for development.

Nemophila insignis is suitable for pot culture for the decoration of the greenhouse and conservatory. The pots should befil led with light, rich soil, and not more than three plants should be grown in a forty-eight-sized pot, which is the best size to grow them in. Although when planted in the garden they have to take their share of sunshine and it does them no harm, when grown under glass they should be shaded from the midday sun on bright days. These sweet little flowers belong more to the grove than the open prairie, and when grown as pot plants full sunshine is harmful to them. There are several varieties in commerce, but for general garden purposes none is superior to the type. *A. P. C.*

ALPINE GARDEN.

CLAYTONIA AUSTRALASICA.

If too rampant for the choicer parts of the rock garden, this little carpeting plant may be very useful in the part shade of woodland, about the stones of flagged walks and any other place of the kind where a ground cover is desired, and where it can be permitted to spread at will.

The plant creeps rapidly underground, and soon covers a considerable space with its narrow, grass-like foliage, barely an inch in height and of a bright, glossy green. During May and June this turf becomes studded with pure white, stemless flowers, each about half-an-inch in width and possessing a distinct family likeness to those of the other species in the pearly lustre of their petals.

C. australasica has withstood over twenty degrees of frost here, and that in a damp, cold part of the garden near the water. *A. T. Johnson, Taly Cafn, North Wales.*

ANAGALLIS.

The blue Pimpernel is worthy of a position in the rock garden, where its richly-coloured flowers will be welcomed during the late summer and early autumn. The seeds may be sown in prepared positions during April, and the seedlings thinned when large enough to handle. The plants grow to a height of about six inches and should be regulated to that distance apart. To bring the plant to perfection a sunny position is required.

SEDUM CAERULEUM.

This pleasing little annual may be grown either on the rockery or in the front of the flower border. The soft blue colour of the flower is charming but not very conspicuous, and for this reason the clumps should be fairly large.

The seedlings should be raised in a warm house during March, and when large enough to handle, pricked out about two inches apart, in boxes containing sandy soil. These boxes may be placed in a cold frame and remain there until the plants are ready for transferring to their permanent quarters.

This Sedum is not very tender, and after undergoing the usual hardening off, may be planted out during May.

In well-drained situations, self-sown seedlings will be found to survive a normal winter, but being small are liable to perish through the lifting action of frost. The height of the plant is about four inches. The seeds may be sown where the plants are to flower, but as they are very small, raising the plants under glass is a more reliable method. *Charles Hodgson.*

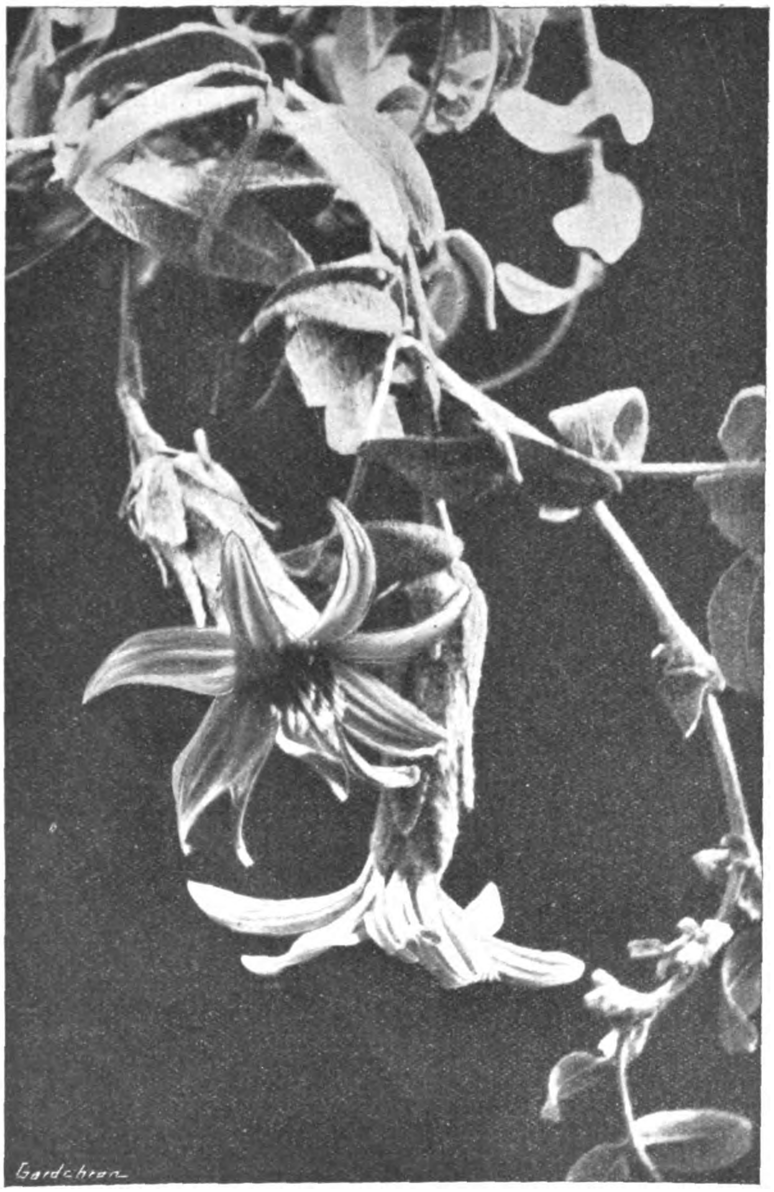

FIG. 65.—MUTISIA CLEMATIS.
R.H.S. Award of Merit, February 9. Flowers pendant, corolla scarlet.
Shown by Lieut.-Col. Messel (see p. 123).

NOTES FROM A WELSH GARDEN.

Olearia semi-dentata is such a beautiful shrub—probably the best of the genus—that it is hard to have to abandon it on account of its being too tender for this immediate locality. The early December frosts which killed our oldest specimen were undoubtedly abnormally severe, but, even so, we have lost this fine species before, and I doubt if it will be replaced this time. In the same "black list" must be placed Cistus vaginatus, a remarkably handsome species from Teneriffe, which is much the tenderest of all its kind grown here. Even in a favoured spot against a wall, this has perished. Cantua buxifolia is another shrub of which a similar tale must be told, for even if it does not get killed by frost, fresh growth always starting from the base, it has never yet flowered. And after all, why attempt to grow "doubtfuls" when there is such a wide choice of really reliable and equally attractive subjects which will take their places ?

The many weeks of mild and muggy weather which we have had since December have brought about the inevitable premature development of leaf and flower on all sides. Rhododendron Nobleanum was in bloom soon after mid-January, R. praecox being but a few days later. These are at least a month before their usual date with us and, as I write (February 10), R. Christmas Cheer, a R. causasicum cross, is breaking into colour. This latter, with its neat, compact trusses in bright rose and white, is very delightful in the early year, and its blooms seem better able to withstand wintry weather than those of most early Rhododendrons.

One of the most interesting plants now in flower is the tiny Arcteria nana, which is apparently quite satisfied with a bed of old leaf-soil and grit on the cool side in the rock garden. Though barely three inches across, and only about half as tall, this little mite from Spitzbergen is laden with blossom, every twig terminating in a crowded raceme of creamy-white, urn-shaped bells which smell strongly of honey. At first we had this little plant in a partially shaded bed in the woodland, given over to dwarf Gaultherias and kindred plants, but it resented the drip or lack of light and was undoubtedly "in decline" when it was moved to its present place with practically full overhead exposure, and where, as I have said, it is vigorous and healthy. An excellent illustration of A. nana appeared in *The Gardeners' Chronicle* of April 19, 1924.

Anemone Hepatica has been in evidence for some weeks. Indeed, a robust, pure white—presumably A. H. triloba alba—had copious clusters of flowers before the Winter Aconites and Snowdrops had appeared, and this white form, it is worthy of note, is the only one of this genus which produces self-sown seedlings here. In fact, it is fully and freshly naturalised, whereas I cannot recall having found a single seedling of any coloured variety. All these Hepaticas are so charming that is is difficult to make comparisons, but a "best half-dozen" would surely have to include A. H. angulosa lilacina grandiflora, A. H. angulosa rosea (a very rich Cherry-carmine), A. H. triloba violacea, or any other good single dark blue, a single pink and the white mentioned. Tastes will always differ, but the single blooms in these cheerful tokens of the early year are to my mind more beautiful than the doubles.

Crocus Tommasinianus in open spots in the woodland will be in full flower before these notes are in print; there are sunny places already glittering with the common yellow Dutch Crocus—always the earliest and one which, if it never sets seed, is constantly spreading, the corms probably being carried about by mice. Species of Muscari are showing their various blues, dainty M. azureus in the clearest Cambridge blue being especially lovely. Dog's-tooth Violets, notably Erythronium revolutum Watsonii and E. americanum, have unsheathed their buds much before their usual date, and Cyclamen Coum is brightening the densest shade with its lively rose carmine flowers.

On a warm border, Iris reticulata is in bloom, and more charming features the season does not yield than these violet-scented, rich purple and gold blossoms. I. reticulata is, moreover, a little plant of much discretion, its buds waiting with most commendable patience for a break of genial weather. Many of the early Saxifrages, on the other hand, seem to regard the date with more punctiliousness than the weather. S. Burseriana and some of its allies for example, always seem to march with the Snowdrops unless the weather be very severe, and nothing daunts the bravery of S. apiculata. S. Bursiculata is equally robust, and if it is not as choice a plant as good forms of S. Burseriana (one of its parents) it is exceptionally reliable and trustworthy, thriving and blossoming freely where the true S. Burseriana of more exalted standard is not so successful in winter and more impatient of summer heat. S. Faldonside and S. Grisebachii are in bloom, and beyond praise, and the delightful S. kewensis is studded with buds.

Omphalodes cappadocica is always precocious, the first of its kind here to give colour, and what an exquisite blue it is! But its season is a long one, and a goodly plantation, ever extending by self-sown seedlings, will not be at its best until the branches of Magnolia stellata above it are a-flutter with their white-rayed flowers. Indeed, it is not unusual for O. cappadocica to be still flowering gaily when a bush of Rhododendron occidentale, which also stands among it, is announcing the arrival of full summer with its fragrant white blooms.

Quite the most remarkable survival of the very severe weather we have had is Lithospermum rosmarinifolium. As stated in earlier notes, this fine subject came into flower this season in autumn, several weeks before its usual date. Its flowers and a good many buds were of course, destroyed by the frost, but the shrub itself did not suffer and it is now better than ever, its glossy dark green foliage being covered with the wonderful Gentian-blue flowers.

In his "Notes from Glasnevin" (p. 98), Mr. W. J. Besant refers to the advisability of growing L. rosmarinifolium in poor rather than rich soil, and suggests the "top of a dry wall." I heartily concur in that opinion, and have no doubt but that the safety and success of my old plant are due to the fact that it is in soil that is two-thirds stones and grit (with a little old mortar), and this is on the top of a low and very dry retaining wall over which the branches hang to the extent of nearly three feet.

Daphne Blagayana is in full bloom in the part shade of woodland trees, its creamy clusters filling the air about it with a delicious fragrance on every mild day. So soon as its flowers are over the plant will be top-dressed with leaf mould and grit well up to the foliage, the branches being held down by stones. To this application in spring and early autumn we attribute our success with this rather fastidious alpine. D. Dauphinii has broken into flower again since the frost. In spite of the delicate appearance of its fresh green leaves, this Daphne (supposed to be a D. odora × D. collina hybrid is quite hardy here, even in such a winter as this has been.

With the exception of Veronica Traversii and V. salicifolia, the taller shrubby members of this genus do not produce self-sown seedlings. Very occasionally one may find a seedling from some of the hybrids of the speciosa group and a few days ago I found, for the first time, two or three little plants which are undoubtedly the offspring of the odd-looking, V. macroura. In spite of its curiously crumpled appearance, this prostrate species is undoubtedly one of the more attractive of the larger shrubby Veronicas having pure white flowers. It is, moreover, exceptionally hardy and robust. It is not often that Veronica chathamica is affected by frost here, but this winter a large specimen trailing over a low retaining wall has been rather badly injured. Still, considering the severity of the frost, if this plant had not been tolerably hardy it would never have survived at all.

V. chathamica is one of the very few members of its genus which are perfectly prostrate.
A. T. Johnson, Ro Wen, Talycafn, N. Wales.

MESEMBRYANTHEMUM.

(Continued from p. 117).

1.—CONOPHYTUM, Haw.

(Additions and Corrections; see vol. LXXVIII, p. 450).

In the *Zeitschrift fur Sukkulentenkunde*, vol. II, p. 137 (December, 1925), Mr. G. Schwantes has proposed to separate from the genus Conophytum those species belonging to the same group as C. bilobum, C. Elishae and allies (and he also includes the very different Lithops Friedrichiae among them), and to form of them a new genus, to which he gives the name Derenbergia, stating that Derenbergia differs from Conophytum as follows:—(1) by the absence of bracts; (2) by having a 4-celled capsule; (3) by the shape of the growths. From this statement it would seem that Mr. Schwantes has neither dissected these plants nor even read my descriptions of them, or he would have found:—(1) that if flowering growths had been cut open a small pair of bracts would have been seen to be present upon the pedicel (which is concealed in the body of the growth) of the flower in C. bilobum, C. Elishae and allies, and upon that of every other species of Conophytum! (2) That the ovary and capsule of C. bilobum, C. Elishae and some other species is 4, 5 or 6-celled in different flowers of the same plant, and varies in different years! (3) As to the shape of the growths, that is only a specific, not a generic character. Conophytum contains several types of form, and around each type several species may be grouped, and the groups mostly grade into each other without well defined limits.

Therefore, as there are no valid characters whatever by which Derenbergia can be separated from Conophytum it can only rank as a synonym of that genus. No new species are described under that generic name, but some of the species described by myself are transferred to it.

When I described C. Meyeri, N. E. Br., in *The Gardeners' Chronicle*, 1925, vol. LXXVIII, p. 484, I described the growths as they appeared shortly after they were received, but now they have "plumped up," they are almost globose in form, with no trace of any compression.

In *The Gardeners' Chronicle*, 1926, vol. LXXIX, "C. Whettsteinii, N. E. Br." and "C. Eliskae" p. 12, columns 1 and 3, should be corrected to *C. Wettsteinii and C. Elishae* respectively. I regret that these errors were quite overlooked by myself in the proof.

4.—RIMARIA, N. E. Br.

Stemless, succulent perennials, with the growths under natural conditions usually crowded upon the top of a deeply descending rootstock, rarely solitary. Growths subglobose or compressed-ovoid, formed of two (or when forming a new growth, four) hemispherical or thick, ovate, equal or unequal, leaves united for half or two-thirds of their length, and their free parts pressed closely together, entire or with minute teeth on their edges and sometimes along a slight keel on the top; smooth, glabrous or puberulous with microscopic soft points, green or whitish, or dove-grey, without dots. Flowers solitary. Pedicel partly or at least the ovary exserted, bearing a pair of bracts included in the body of the growth. Calyx subequally 5–9-lobed down to its union with the ovary. Petals numerous, free, in about 3 series, linear. Stamens numerous, erect, no staminodes. Style none; stigmas 7–15, erect filiform. Ovary inferior, 7–15-celled; placentas on the floor of the cells. Capsule shallow, flattish on the top, with 7–15 valves and cells; valves, when wetted, widely spreading or more or less reflexed; expanding-keels more or less diverging, with broad, membranous, marginal wings; cells roofed with flat, flexible, membranous, semitransparent cell-wings; no tubercle at the opening. Seeds many in a cell, very small, subglobose, with a nipple at one end, smooth.

Species 4, natives of the Karoo region of South Africa. The type of the genus is R. Heathii, N. E. Br.

The name is derived from the Latin, *rima*, a cleft or fissure, in allusion to the crack-like cleft between the closely applied faces of the leaves when the plant is at rest.

This genus is readily distinguished from nearly all others of the Mesembryanthemum tribe by its dwarf, stemless habit, subglobose or compressed-obovoid or oblong growths of firm substance, with the two leaves of which they are composed closed tightly together during the resting period. The only genera with which it can be confused are Gibbaeum and Didymaotus. From those few species of Gibbaeum that have equal or subequal leaves, the firmer substance of the growths, and the more numerous (7-15) stigmas, valves and cells of the ovary well distinguish it; and from Didymaotus, the absence of dots upon the growths, the central (not lateral) flowers and more numerous stigmas readily separate it. The sectional structure of the flower resembles that of Lithops, but in its vegetative character, more numerous stigmas and cells of the ovary, and especially by the presence of cell-wings roofing the cells of the capsule, it is very different.

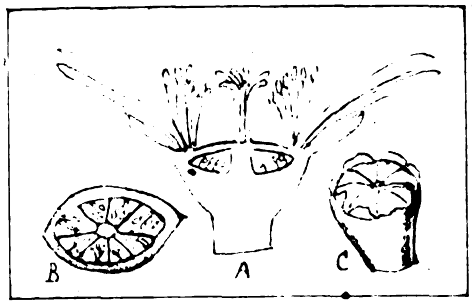

FIG. 66.—RIMARIA HEATHII.

A. Diagram of the structure of the flower.
B. Transverse section of ovary.
C. Capsule.

The diagramatic figures (Fig. 66) showing the structure of this genus are not drawn to any scale: the figure of the capsule is about one-and-a-half times natural size.

KEY TO THE SPECIES.

1.—Surface of the growths microscopically puberulous, velvety to the touch; leaves or lobes with minute teeth on their edges and often along the faint keel. **3, Roodiae.**

Surface of the growths glabrous, no teeth. **2**

2.—Surface faintly rugulose and microscopically granulate, of a light dove-grey colour. **4, Pole Evansii.**

Surface smooth, whitish, glaucous-green, or of a pale reddish tint. **3**

3.—Growths 1-1¾ inch high, 8-15 lines broad and 6-10 lines thick; flowers white. **1, Heathii.**

Growths ½-1 inch high, 4-8 lines broad and 3-6 lines thick; flowers unknown. **2, dubia.**

1.—**R. Heathii, N. E. Br.** (Figs. 66, 67). Rootstock thick, deeply descending. Growths crowded upon the top of the rootstock, or, under cultivation, at the ends of short prostrate branches, subglobose and from 1-2 inches in diameter or compressed obovoid and 1-1¾ inch high, 8-15 lines broad and 6-10 lines thick, with the fissure between the leaves 5-8 lines deep, and the top of the leaves rounded or faintly keeled, quite entire, smooth, glabrous, uniformly whitish to pale glaucous-green, or sometimes tinted brownish or reddish, without spots or other markings. Pedicel equalling or slightly exceeding the growths, stout, flattened, with acute edges and 5-6 lines broad, glabrous. Calyx compressed, subequally 8-9-lobed, glabrous; lobes 3-4 lines long, 2-2½ lines broad, oblong, obtuse, mostly with membranous edges. Corolla 14-18 lines in diameter, expanding about midday and closing at the latter part of the afternoon; petals numerous, in 3-4 series, free, subequal, 7-9 lines long and in ¼-¾ line broad, linear, obtuse or acute, white. Stamens numerous, in several series, erect and loose or spreading so as to form a ring, 1½-3 lines long; filaments filiform, not dilated nor ciliate at the base, white; anthers creamy white. Stigmas 8-9, erect, with spreading tips, about 2 lines long, filiform or subulate, acute, green. Ovary flat or very slightly convex at the top, 8-9-celled. Capsule about 5 lines in diameter, very slightly convex, with 8-9 raised ridges on the top, and with 8-9 valves and cells; valves with the expanding-keels diverging from their base, adnate to about the middle of the valve with the upper part free, provided with broad, rounded, membranous wings that are often united in pairs between the valves; cells roofed with flattish membranous cell-wings, without a tubercle at the opening. Seeds very numerous in each cell, about ¼ line in diameter, subglobose, pale brown, with a dark brown nipple, smooth.

Mesembryanthemum Heathii, N. E. Br., in *Journ. Linn. Soc. Bot.*, vol. XLV., p. 67.

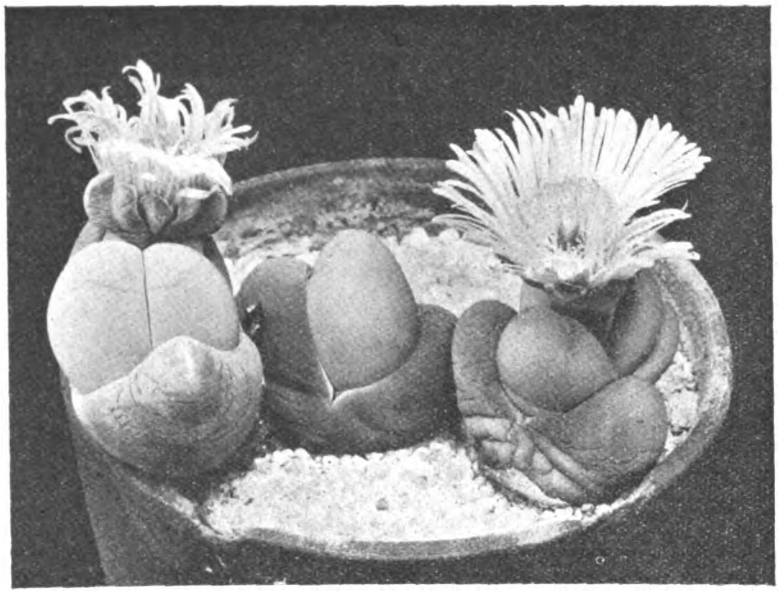

FIG. 67.—RIMARIA HEATHII, N. E. BR.

Natural size. From a photograph by Dr. Rodier Heath.

Ladismith Division: In the Klein Karoo between Garcias Pass and Ladismith, Pillans 890!; near Adams Kraal, Muir 3415!; at Hondewater, Muir 3665! 3776!, and 3777! at Algeryns Kraal, Muir 3775!; and without precise locality, Muir 3773, 3774!

This very distinct plant was first introduced in 1906 by Mr. N. S. Pillans, who sent plants of it to Kew, which soon died; a capsule upon one of them was, however, given to Dr. F. H. Rodier Heath, who raised some plants from the seeds, which is the source whence most of the plants now in cultivation have originated.

According to Dr. J. Muir it is common locally in several parts of the Klein Karoo, and is known to the Dutch farmers by the name of "Vogelstruis Water," *i.e.*, Ostrich-water, as Ostriches eat them for the water that is contained in their succulent growths.

Kept constantly in a greenhouse, this plant seldom flowers, but in hot, sunny summers, if given as much open air treatment as possible, it is less difficult to get it to flower. *N. E. Brown.*

(*To be continued.*)

IRIS GARDEN.

IRIS UNGUICULARIS.

I READ with great interest of Mr. W. Auton's remarkable success with this Iris (see *Gard. Chron.*, January 23, p. 60), and congratulate him not only on the large numbers of flowers produced, but also on the care taken by him to convey to your readers full details of his methods of culture.

In our mild and humid west we cannot hope to emulate Mr. Auton's success with this fine winter-flowering Iris, but much may be done by following his plan of a raised, narrow border, and planting in very poor stony or sandy soil, as these conditions more nearly conform to those of the country of its origin, Algeria. Another plan which I have tried, with fair success, is to plant at the foot of a south wall where the gravel path goes right up to the wall, planting actually in the path. Although this Iris had, previous to that, been growing for many years without producing a flower on sheltered borders, it responded to this starved rooting-medium the first winter by producing a number of flowers, and continues to bloom freely each successive year.

In the *Gardener's Pocket Diary* issued by the R.H.S., a note on this Iris has appeared for a number of years, and it is recommended to cut its leaves back to half their length in May or June, as a certain remedy for its non-flowering. If this is carried out and proves correct, many more flowers of this lovely Iris should be forthcoming. It is certainly worth trying where the plants persistently refuse to flower, either because they are in a very rich soil or in too sheltered a spot.

A number of years ago I saved some seeds from this Iris and sowed them in a box filled with ordinary soil. No seedling appeared for eighteen months, and, growing impatient at the long delay, I upset the box and its contents on to the Peach-house border, simply picking off the crocks and scattering the soil. Picture my astonishment when about a month later some thirty or forty of the seeds germinated, as if they preferred my rough treatment to the more usual method of seed-sowing. This Iris is frequently grown in gardens under its synonym I. stylosa; the flowers are somewhat fugitive and they are too tender for packing for travelling. *A. T. Harrison, Culzean Castle Gardens, Ayrshire.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

CLASSICAL AND LEGENDARY GARDENS.

II.—The Gardens of Adonis.

THE story of Adonis is of high antiquity, and, in one of its forms, of Phoenicean origin. With much of the legend, or legends rather, for they are numerous, the modern mind can have but scant sympathy. To modify a saying of J. R. Lowell—time makes this ancient law uncouth. It seems, however, that the story is one of the ways in which the Eastern intellect endeavoured to set forth among other things, the mysterious powers of nature. At his birth the beautiful child Adonis was placed in charge of Persephone, who, later, declined to surrender her protege. Adonis became the lover of Aphrodite, and so great was the grief of the latter at his death that he was permitted to spend one half of each year with her on earth, the other half being passed in the nether world. Aphrodite, according to the mythologists, represented the fructifying powers of nature, while Adonis symbolized the death of nature in winter. In this case the legend must have originated amongst a people who resided in a region where the year was nearly equally divided into two parts of six months each. The death of Adonis and his return to life gave occasion for annual celebrations known as Adonai, at Athens, Alexandria, Byblos and elsewhere.

According to Cox, one of the staunch supporters of the Solar Myth, "the dawn, as bringing back the sun and recalling to life the slumbering powers of nature, is especially the lover of the bright fruits and flowers which gladden her pathway. In other words, Aphrodite loves Adonis and would have him for ever with her. The word Adonis is manifestly Semitic, and the influence of Asiatic thought may be readily admitted in the later developments of this myth; but the myth itself is one which must be suggested to the inhabitants of every country where there is any visible alteration or succession of seasons." In another place (*Mythology of the Aryan Nations*) he writes of the sensualizing of the legend of Adonis, which represents the sun calling the earth back to life.

Much has been written respecting the similarity which exists between this and other legends, such as the Hebrew Tammuz with its Babylonian equivalents, and those more western forms to be found in Scandinavian folklore. But while the myth is admitted by many writers to be connected with the changes of season, W. R. Smith and others give it a different interpretation. The question, however, is too complex for our present purposes, and I turn to that aspect of it which is of more immediate interest to lovers of plants and the garden.

It is well-known that more than one plant bears the name of Adonis. The name Adonis-flower or Flos Adonis was applied to the Pheasant's Eye (Adonis autumnalis, L.) by Linnaeus, who was very fond of using classical names for plants and insects. The name Bluts-Tröpfchen which is given to another species (Adonis aestivalis) by the German people recalls the story of the untimely end of our hero. One variant has it that, having received a fatal wound from a boar, he poured out his life-blood on the greensward, whence sprang the red Adonis flower. Ovid and others have repeated and added to the legend, telling us now that the flower sprang from his blood, and again that it was due to the tears of Venus on account of his death. Yet another version has it that the Rose sprang from the blood and the Windflower from the tear.

> "But gentle flowers are born and bloom around
> From every drop that falls upon the ground,
> Where streams his blood, there blushing springs the Rose.
> And where a tear has dropped a Windflower blows."

Since these forms do not suffice the poets and romancers, we further learn that the Anemone blossomed from the corpse of Adonis, while the gore which flowed from the foot of the goddess, who trod on a thorn while hastening to his aid, turned the white Rose to red. Shakespeare has an allusion to the legend in Venus and Adonis:—

> "By this, the boy that by her side lay kill'd
> Was melted like a vapour from her sight,
> And in his blood that on the ground lay spill'd
> A purple flower sprung up, chequer'd with white,
> Resembling well his pale cheeks, and the blood
> Which in round drops upon their whiteness stood."

In an ancient codex of Dioscorides, which is preserved in Vienna, is to be found an illustration of the Adonis flower as described by Ovid, under the name Argemone. As one of our Poppies bears this name we are reminded that the red Poppies of Flanders were said to have sprung from the blood of the soldiers who perished in the battle of Waterloo!

Among the Romans, Adonis was one of the divinities, of which there were several, who had gardens under their protection. We find, therefore, that the term "Gardens of Adonis" has several meanings. Not only were they the resorts of pleasure which he had under his care; they were also pleasaunces devoted to his honour. Eden, says Milton, was a place of delight;

> "Spot more delicious than those gardens feign'd
> Or of revived Adonis, or renown'd
> Alcinous, host of old Laertes' son;
> Or that, not mystic, where the sapient king
> Held dalliance with his fair Egyptian spouse."

The visitor to Rome will not need to be reminded of the gardens planted by Domitian, near his Stadium, in honour of Adonis, rendered famous as being the place where St. Sebastian suffered. Hare's description is as follows:—"A lane runs up to the right from the Arch of Titus. On the left is a gateway surmounted by a faded fresco of S. Sebastian. Here is the entrance to a wild and beautiful garden possessing most lovely views of the various ruins, occupying the site of the Gardens of Adonis. This garden is the place where S. Sebastian underwent his (so-called) martyrdom, and will call to mind the many fine pictures scattered over Europe, of the beautiful saint, bound to a tree, and pierced with arrows. The finest of these are the Domenichino. in S. Maria degli Angeli, and the Sodoma at Florence. He is sometimes represented as bound to an Orange tree, and sometimes, as in the Guido at Bologna, to a Cypress, like those we still see on this spot." (*Walks in Rome*).

I visited these Gardens of Adonis on May Day, 1925. It must, however, be noted that while Pliny mentions the Gardens of Adonis, as Milton does, with those of Alcinous and the Hesperides, and Spenser as—"The first seminary of all things that are born to live and die according to their kinds," the Greek writers frequently employ the term in quite a different sense. From the many allusions to the subject which may be found, I quote that of Professor Sayce. "It was, above all, in the Phoenician town of Gebal or Byblos (eight miles to the north of Beirut) that the death of Adonis was celebrated. Hard by was the river of Adonis, the Nahr Ibrahim of to-day, which rolled through a rocky gorge into the sea. Each year, when the rains and melting snows of spring stained its waters with the red marl of the mountains, the people of Gebal beheld in it the blood of the slaughtered Sun-god. It was then, in the month of January or June, that the funeral festival of the god was held. For seven days it lasted. 'Gardens of Adonis,' as they were called, were planted—pots filled with earth and cut herbs, which soon withered away in the fierce heat of the summer sun—fitting emblems of the lost Adonis himself. Adonis, the young, the beautiful, the beloved of Ashtoreth, was dead; the bright sun of the springtide, like the verdure of nature which he had called into life, was slain and withered by the hot blasts of the summer."

The plants which were used on these occasions were not always "cut herbs," or sprays which withered when the sun shone. In the little earthen pots Lettuce and Fennel, Cress and other plants were grown, while a wooden image of the god was placed in their midst. These were all symbolical. The Lettuce, for example, was regarded by the ancients as a suitable salad for times of mourning, on which account "they employed it largely in their funeral repasts in commemoration of the death of Adonis whom Venus had concealed in a bed of Lettuces," where he was found and slain by the wild boar which came there to pasture. Fennel also has much ancient lore attached to it, and its use was symbolical.

The name for garden in Greek was *Kêpos*, and our Greek Lexicons inform us the 'Gardens of Adonis' (*Adonidos kepoi*) were "cresses and other plants grown quickly in pots." From this arose the proverbial use of the term for amusements and pastimes.

We are thus led to note one other use of the phrase. Among the scholars whom Leo X gathered around him at the beginning of the sixteenth century was a learned Italian named Guarino, whose first publication consisted of a collection of remains from a large number of Greek grammarians. This bore a very elaborate title in Greek, which was given in Latin as *Thesaurus, Cornucopiae et Horti Adonidis*, the printer informing us in his preface that it might with equal propriety be known as the "Horn of Plenty, a Thesaurus, or the Gardens of Adonis." *Hilderic Friend*

TREES AND SHRUBS.

CAMELLIAS FRUITING.

In reference to the note (p. 79) on this subject, it may be of interest to record that several plants have been raised from seeds, ripened on semi-double varieties growing in the open ground in these gardens.

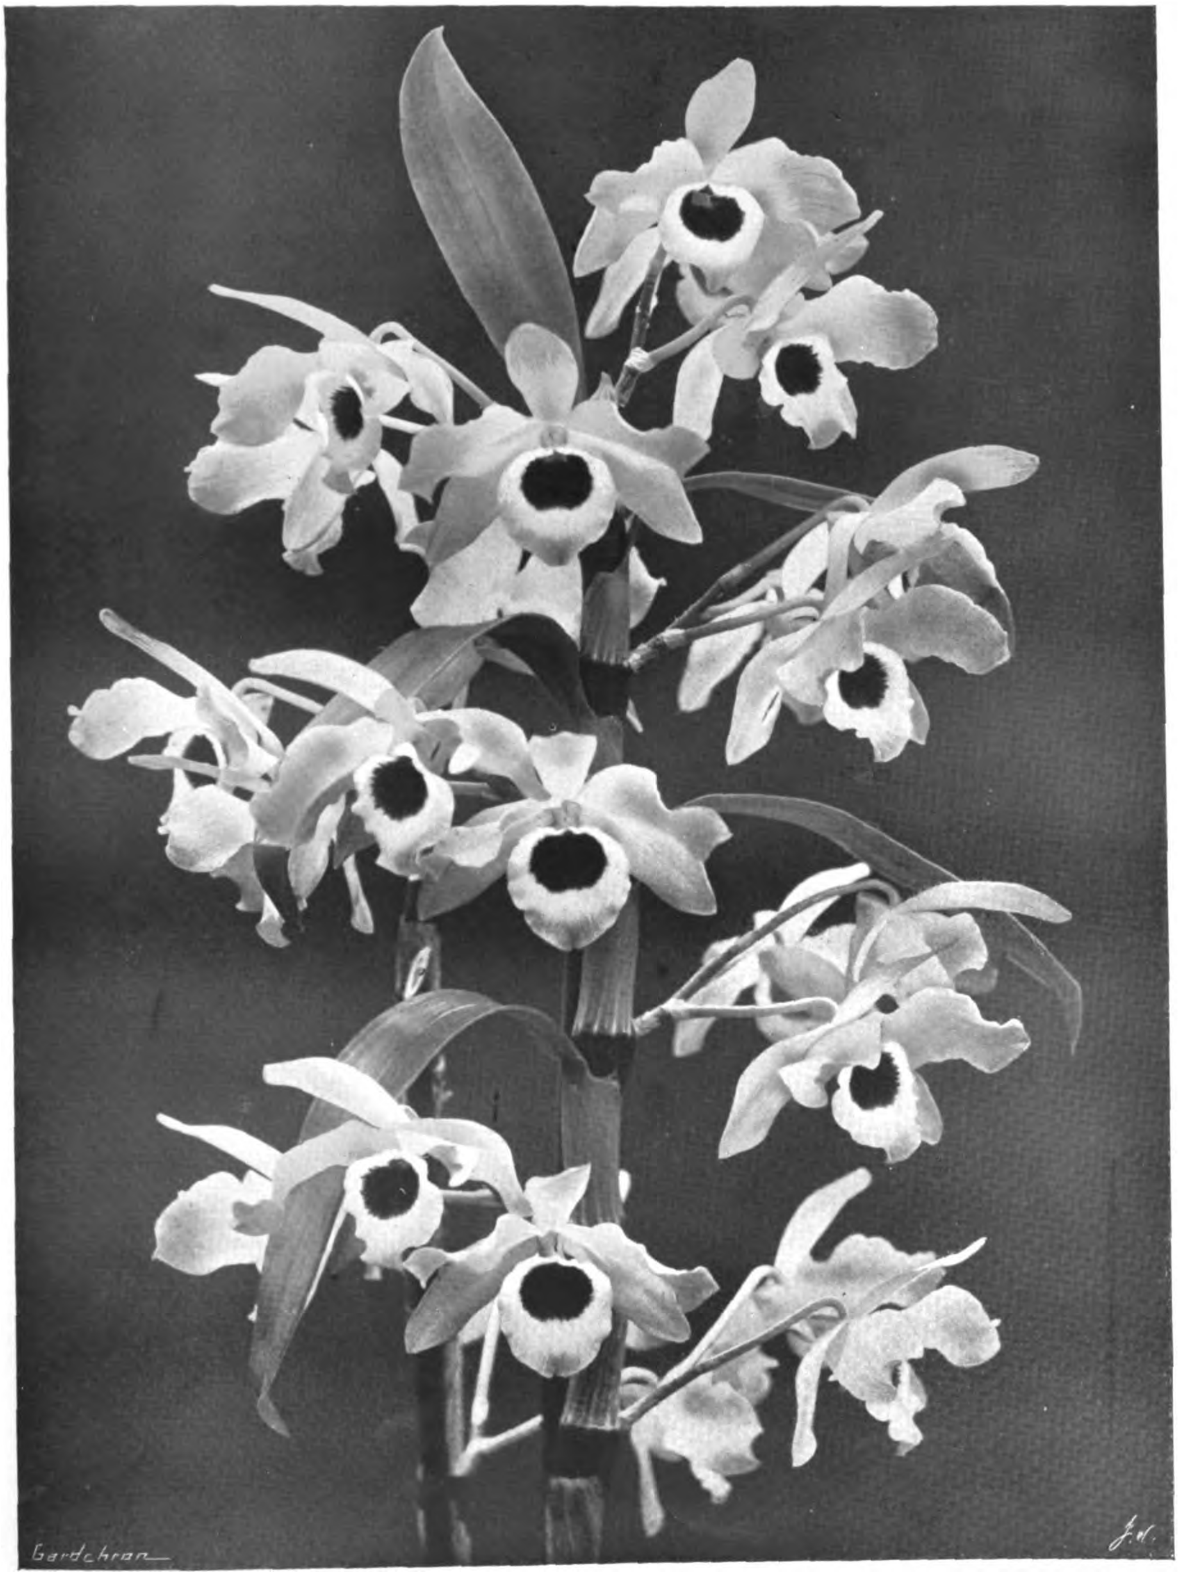
The seedlings are now about two feet in height, and will probably be planted outside this season.

C. Donckelaari and a series of semi-double varieties, such as Jupiter and Ceres, sent out about twenty years ago, by Messrs. Paul and Sons, produce seeds the most freely.

I have never seen fruit on Camellia Sasanqua or Lady Clare, though the latter is one of the best of the semi-doubles, and grows and flowers freely in the open air.

I have closely examined C. cuspidata and find that it fruited last summer; a spray cut from the bush is enclosed. *J. Comber, Nyman's Gardens, Handcross.*

Supplement to The GARDENERS' CHRONICLE



DENDROBIUM GATTON MONARCH.

RHODODENDRON NOBLEANUM.

Although nearly a century has elapsed since Rhododendron Nobleanum was raised at the Knap Hill Nursery, it still remains one of the most popular of the hybrids derived from R. arboreum, notwithstanding the competition it has to withstand from hosts of more recent introductions. Its other parent was R. caucasicum. Under favourable conditions, R. Nobleanum becomes a small tree, attaining a stature of fifteen feet, and producing an abundance of bright, rose-coloured flowers. Its precocity in blooming makes a strong appeal, for any hardy plant that flowers in January and February commends itself to garden lovers; but this early-flowering habit is also a weakness inasmuch as many of the brilliant flowers are destroyed when sharp frosts occur. In the southern and south-western counties, in south Wales and in southern Ireland, R. Nobleanum seldom suffers as a result of its efforts to brighten the early days of the new year, but, even so a sheltering screen of trees on the north and east will ensure protection from cold winds and bright sunshine. It often happens that bright sunshine acting on slightly frozen flowers will spoil the display, whereas if the flowers thaw before the sunshine reaches them little harm will be done.

The specimen illustrated (Fig. 68) represents a plant in the garden of Admiral A. W. Heneage-Vivian, at Clyne Castle, Blackpill, Swansea. It is fifteen feet high, and in mid-January carried eight hundred trusses of flowers.

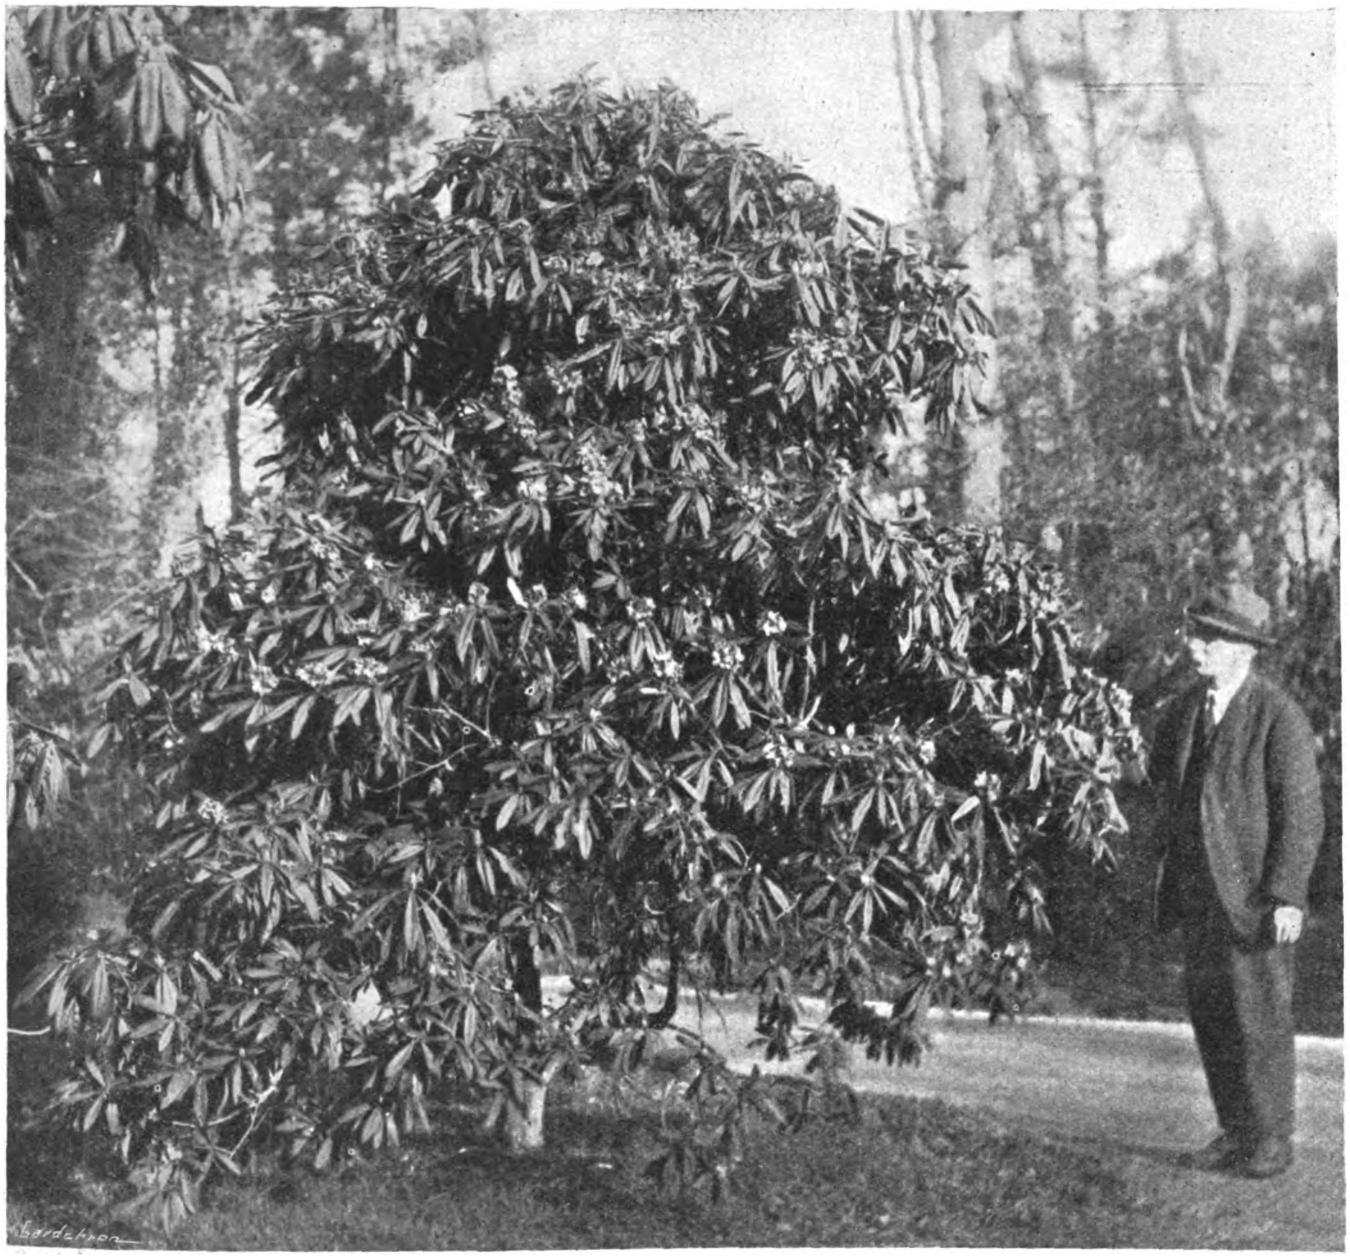


FIG. 68.—RHODODENDRON NOBLEANUM AT CLYNE CASTLE, BLACKPILL, SWANSEA.

ÆSCULUS PARVIFLORA.

Trained to a single stem, Æsculus parviflora will grow to a considerable height, but the nature of the plant is to throw up suckers and so form a broad mass some six feet or more in height and twice as much across.

The leaves, consisting of five or more leaflets, are handsome, and the upright flower panicles which terminate the branches are from six inches to ten inches in length, and proportionally wide. The flowers are pure white, to which the red anthers impart a pink flush.

In a good soil that is not too dry, Æ. parviflora will flower abundantly, and the fact that its blooming season is July and August gives the shrub an additional value. A well-grown specimen in full blossom is a most charming sight, the habit being graceful, and the abundant, tall spires of blossom singularly attractive. This species, moreover, is absolutely hardy and easy of cultivation. It is a native of the south-east United States, whence it was introduced by John Fraser in 1785. *J.*

POLYGONUM BALDSCHUANICUM AND P. AUBERTII.

In reply to Mr. R. Gardner's note in your issue of January 30 concerning the above plants, I feel sure there are sufficient botanical differences to enable anyone to distinguish the two. P. baldschuanicum has larger leaves and of a darker green than those of P. Aubertii. The former starts flowering in August, has pink flowers, and is not very free, while the latter will flower under favourable conditions by the end of June and continue flowering throughout the summer and autumn, bearing masses of nearly white flowers. The flowers are smaller than those of the former, but appear in much greater number.

P. Aubertii is by far the most preferable plant of the two, as it has a stronger constitution and is not so subject to disease. But the principal point is, that the true P. baldschuanicum does not flower so freely, and often does not flower at all the first year after planting. In the trade there is much confusion between the two kinds as they sometimes vary a little in habit and also in the colour of the flowers, which is always between pink and white. *B. Ruys, Royal Moerheim Nurseries, Dedemsvaart, Holland.*

BERBERIS SANGUINEA.

THIS evergreen Chinese Barberry is usually the first to flower here, and if it is not one of the most ornamental species there is a distinction and attractiveness about the little shrub when its bluish-green foliage is strung with the hanging yellow "lanterns," each canopied by conspicuous crimson sepals and suspended by a stalk of the same bright colour.

In dry, poor soil, B. sanguinea does not grow much higher than four feet here, but it is said to attain double that stature in a better medium. It is a very dense shrub and spiny. The long, narrow leaves are also armed at the tips, and the slender branches are gracefully arched. The fruit consists of a blue-black berry.

This is apparently a mountain species and quite hardy. It was introduced to this country from France in 1898. *A. T. Johnson, Taly Cafn, North Wales.*

PUBLIC PARKS AND GARDENS.

THE Town Council of Guildford has received sanction to borrow £5,808 for the purchase of land at Stoughton for a new recreation ground.

THE Ministry of Health recently held an inquiry at the Portishead Council Offices into an application by the Urban District Council for sanction to borrow £500 for the adaptation and development of Portishead Battery and grounds as public pleasure grounds.

THE general superintendent of the Manchester Parks (Mr. W. W. Pettigrew) has suggested to the Parks Committee that a central nursery for propagating half-hardy plants which are used for bedding and for the embellishment of the different parks and open spaces should be provided. Some of the present glasshouses are in a dilapidated condition and not therefore suitable for the purpose, and the superintendent's suggestion is that, seeing the Corportation has one hundred acres of land at the Carrington Moss nurseries for the propagation of trees, it would be an ideal place for a nursery. Last year the department raised about 300,000 plants under glass, but had to buy 12,000 Pelargoniums for bedding purposes from nurserymen.

The construction and planting of the two new parks on the southern side of the city was another subject before the Committee. The extent of the new park at Fog Lane is forty-nine acres, and that of Chorlton thirty-nine acres. No definite date, it appeared, can be given as to the availability of these parks, but it is thought probable that they may come into use in 1929. The Committee agreed, on Mr. Pettigrew's recommendation, to plant in these new parks ornamental shrubs and trees such as are not to be found in the northern parks, in consequence of unfavourable atmospheric conditions, and similar to those grown in other southern districts.

The Committee had received a letter from Professor Weiss, on behalf of the Ecological Society, expressing the appreciation of members of the Society for affording them opportunities of inspecting the Cactus house at Alexandra Park, and the fine collection of succulent plants there to be seen.

WALLASAY TOWN COUNCIL has decided to apply to the Ministry of Health for sanction to borrow £30,000, the purchase price of Upton Park. Half the area will be utilised as a recreation ground, the remaining half for other purposes.

THE Corporation of Hull has made application to the Ministry of Health for sanction to borrow £11,500 for laying out land between Pickering Road and Anlaby Park Road for public walks and pleasure grounds.

THE Urban District Council of Llandudno is to purchase five acres of land between Riviere Avenue and Rumania Drive for a recreation ground.

TETRACHLORETHANE AS A GLASS-HOUSE FUMIGANT.

SEVERAL correspondents in recent issues of *The Gardeners' Chronicle* (vol. LXXVIII, p 488, and vol. LXXIX, pp. 35 and 86) have referred to the use of tetrachlorethane as a fumigant against White or Snowy Fly on plants growing under glass, but warning should be given to all those who intend to use this chemical that serious damage will ensue if certain plants are exposed to the gas.

Tetrachlorethane ($C_2H_2Cl_4$) is a non-inflammable, volatile liquid with a boiling point of 147°C., and a specific gravity of 1·6 The advantage of using this fumigant is that the gas is not highly toxic to human beings, and may therefore be used in conservatories opening into rooms, and in small greenhouses where the measurement of a small quantity of sodium cyanide or potassium cyanide is difficult. The present price is 1/4 a pound (=1/10th of a gallon) which makes its use on a commercial scale too costly

This gas was first experimentally used against White Fly on Tomatos by the late Professor Maxwell Lefroy, at Wisley, in 1915, and later by Dr. L. Lloyd at the Lea Valley Experimental Station, Cheshunt, in 1920. (*Annals of Applied Biology*, vol. IX, No. 1, pp. 20 and 21.)

It is sometimes suggested that dipping or spraying plants with contact washes is a ready means of clearing them of White Fly, but experience shows that these operations are useless in the case of plants growing in large pots and borders by reason of the difficulty experienced in directing the wash on to the undersurfaces of the leaves where the ova, nymphs or "scales" and adults congregate. An efficient gas is able to diffuse at normal temperatures and permeate to all parts of the house.

A most important factor in the fumigation of a glasshouse is to ascertain its correct cubical capacity. Careless determinations result either in damaging the plants by an overdose of the gas or a low percentage of insect mortality due to under-estimating the required dosage.

Having ascertained the correct cubical capacity of the house, the measured quantity of the liquid is poured down the central path and the house closed for at least twelve hours; five to ten fluid ounces of tetrachlorethane are sufficient to fumigate 1,000 cubic feet of space. The actual amount of liquid used depends on (1) the season and fecundity of the pest; (2) the type of plant to be fumigated; (3) air tightness of the house; and (4) the degree of infestation. Two or three successive fumigations are essential as the gas is not toxic to the ova, and the minimum dose is often insufficient to kill all the nymphs, protected as they are by their waxy covering and position on the plant. The interval between fumigations varies from three weeks in the early spring and late autumn to ten days in the summer months.

The temperature should be between 65° and 70°, which allows for a regular evaporation and diffusion of the gas. It is not necessary to dry-off the house prior to fumigation as the gas, unlike hydrocyanic-acid gas, is insoluble in water. Fumigation should not be commenced until dusk when assimilation and respiration are reduced to minimum quantities.

Tetrachlorethane is somewhat restricted in its use against pests, for although it is highly toxic to the nymphal and adult stages of White Fly, it has little effect on plant lice (aphides), scale insects and red spider. There are several proprietary materials on the market which have tetrachlorethane as their active base.

The following lists show (A) plants that may be fumigated with safety, using from five to ten ounces to 1,000 cubic feet; and, (B) those that are liable to damage when subjected to the gas—as tested at Wisley.

Chrysanthemums (especially the white varieties), Cinerarias and Dahlias are particularly susceptible to damage by tetrachlorethane and should be removed from houses prior to fumigation. Failure to do this will result either in the plants being killed or in the severe scorching of the leaves and flower buds, the damage showing in three or four days after the operation.

List A: Safe.—Adiantum, Antirrhinum, Asparagus plumosus, Aspidistra, Asters (perennial), Beans (French), Carnations, Coleus, Cucumber, Fuchsia, Heliotrope, Marguerite, Nephrolepis exaltata, Primula malacoides, P. obconica, Sobralia, and Tomato.

List B: Not Safe.—Acer pseudoplatanus (Lloyd), Asparagus Sprengeri, Azaleas (indica, etc.), Barleria purpurea, Chrysanthemums (especially whites), Cinerarias, Dahlias, Eupatorium glandulosum, Pelargoniums (Cape), Primula sinensis, and Salvia. *G. Fox Wilson R.H.S. Laboratory, Wisley.*

FORESTRY.

THE INFLUENCE OF PROLONGED DAYLIGHT IN THE VEGETATIVE SEASON ON THE QUALITY OF CONIFEROUS TIMBER GROWN AT HIGH LATITUDES.

(*Continued from p.* 104).

AT mid-day at the summer solstice at the latitude of 64° N. the chemical intensity of the sunlight is double what it was at the vernal equinox, and probably is much in excess of the *optimum* requirements* of either the Scots Pine or the Larch, while, instead of having alternating, approximately equal, intervals of daylight and darkness, as obtains in the tropical zone, during the greater part of the growing season, they have all the advantages of the protracted illumination of the sub-arctic day, with no real night. In the illustration of the globe as shown in Fig. 69, the position of the earth's axis is represented as it is at the vernal equinox—that is, it is vertical to the plane of the ecliptic, and therefore to the path of the sun's rays, which are represented by the parallel lines. The number of units of chemical light intensity at the latitudes of 0°, 41°, 64°, and 90° are as given in Hann's *Handbook of Climatology* at that time. As seen in the lower half of the illustration† the North Pole of the earth, which has now moved in its path from the vernal equinox to the summer solstice, is inclined towards the sun at an angle of 23½° from the vertical, and at mid-day at this time these forest regions occupy the same position in the sun's rays, and receive the same amount of chemical energy, as Central Spain at the vernal equinox, while at this time the equatorial regions receive approximately one-third more chemical energy than these forest regions, but less than one-half the daylight. In effect, by the earth's movement from the spring equinox to the summer solstice these points change their positions in the sun's rays at mid-day to the extent of 1,600 miles southwards, as measured on the earth's surface, and at latitude 64° N. the units of chemical energy received in a day at the equinox (210) are more than doubled with, however, double the duration of day-light. But, as may be observed from the illustration, while every point on the earth's surface is carried southwards in the sun's rays at mid-day at the summer solstice, at midnight it is carried northwards in space by an equal amount, and, with the exception of those within the arctic circle, every one is cut out of the sun's rays daily for periods varying from approximately twelve hours at the equator to *nil* at the arctic circle.

---

* It is not known exactly what are the limiting factors somewhere between which lies the degree of light intensity at which any particular plant thrives best. It varies during the lifetime of the tree, and it is subject to variation even at the different parts of the same vegetative season.

† This illustration shows the position of the earth's axis at the summer solstice, when it inclines towards the sun at an angle of 23½ degrees from the vertical to the ecliptic, and when every point on its surface is carried 23½ degrees, or over 1,600 miles, southwards, in the sun's rays daily. At midday the terrestrial latitude of 64° N. now occupies the position in the sun's rays which was occupied by the terrestrial latitude of 40½° N. at the vernal equinox, and receives 2·25 times the number of units of chemical light intensity which it received then, while the daylight is doubled in duration. All the other northern latitudes now receive light of the same chemical intensity as was enjoyed by latitudes 23½ degrees farther south at the vernal equinox. For example the northern tropic (23½° N.) has now taken the position in the sun's rays that the equator did at the vernal equinox, and receives the maximum number of 716 units of chemical light intensity, while the equator now occupies the position of the southern tropic (23½° S.).

As we have seen, both at Bailowieska (53° N.) and in Aberdeenshire (57° N.) the quality of naturally-grown timber is inferior to that of Finland and Northern Russia, and it is therefore quite obvious that the superiority of the latter is not so much due to increase in the chemical intensity as it is to the enormous increase in the duration of the daylight in the growing season. Now if, as seems to be the case, a prolongation of the duration in the growing season promotes anabolism in an annual plant like Barley, it almost goes without saying it must also do so in the case of perennial plants generally; but in the case of trees which rear their heads of foliage far above the ground, and in which the cambium cells already exist and only await the necessary warmth to enable them to function and form fresh material when the vegetative season arrives, this action must be more prompt than in the case of more lowly plants, the temperature of which must be largely controlled by that of the soil in which they grow, or of seeds such as Barley, which have, in addition, to spend some time in the process of germination before they even come under the influence of the light, and have afterwards to form superstructures before they can function. In these high latitudes all plants have, perforce, owing to the very limited duration of the growing season, to, metaphorically speaking, "make hay while the sun shines." Not only do they function at high pressure, but they work overtime in order to complete their work before the cessation of growth for the season sets in, and although they do this at a somewhat lower temperature and under weaker illumination than obtains at lower latitudes, they have a much longer working day. In fact, for a short time at the middle of the vegetative season they practically live and work in perpetual daylight. *A. D. Richardson.*

(*To be continued.*)

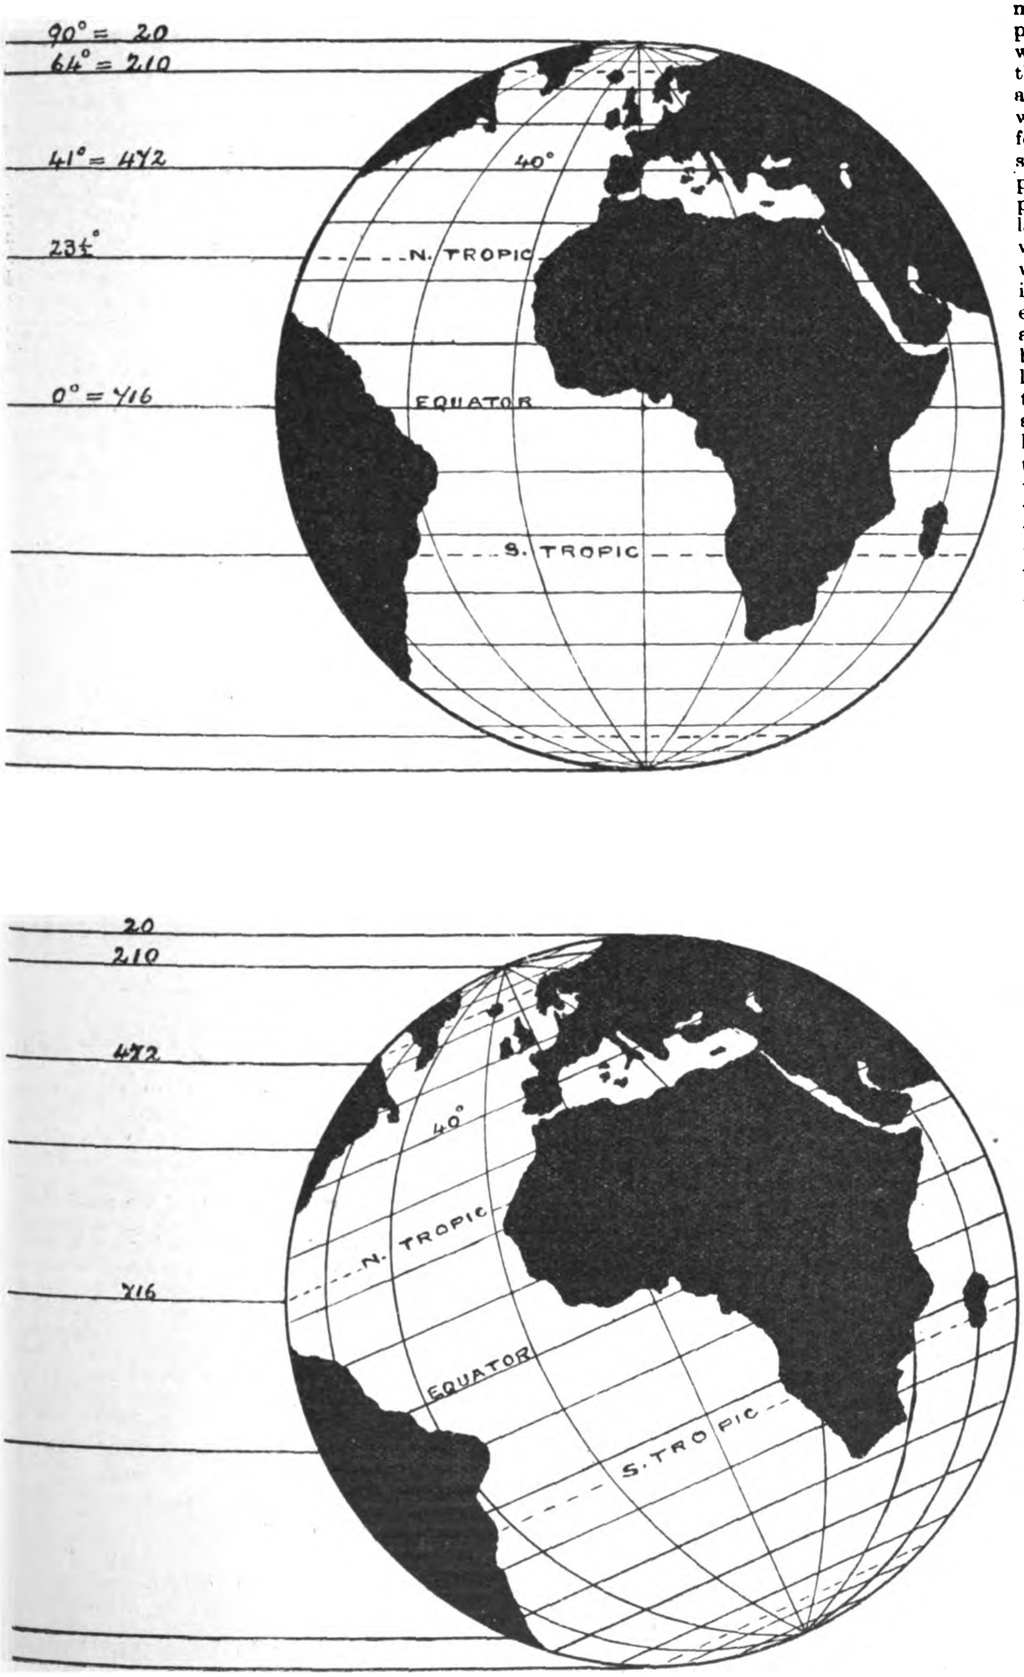

FIG. 69.—INFLUENCE OF DAYLIGHT ON THE GROWTH OF TIMBER.

Upper: Position of the Earth's axis in relation to the Sun's rays (represented by the parallel lines), at the Vernal Equinox. Lower: Position of the Earth at the Summer Solstice.

MARKET FRUIT GARDEN.

Pruning Black Currants.

I have pruned my Black Currants more severely than I expected would be necessary. It has been shown that hard pruning of this crop may result in a serious loss of yield; and, as in these days of bud mite and Nettle-head, the bushes are not likely to stand for many years, it is usually wise to fruit them as heavily as possible. But, with all varieties except Boskoop Giant, I find a difficulty in getting the bushes to make enough growth once they have started to crop. Probably mine is not really good Black Currant soil, for no treatment will induce the bushes to send up many shoots from below ground, as I have seen them do in the West Midlands, for instance.

Most of my bushes of bearing age are of the French type, and they seem to have a habit of almost stopping growth so soon as they begin to crop freely, in spite of manuring. They make splendid growth before they reach that stage. When I began pruning I found that many of the older branches, although covered with fruit spurs, looked worn out, showing little or no terminal growth. I cut them out freely, pruning to a lateral where there was a strong one, and, failing that, to within a few inches of the ground. This is simply the regulation method of pruning. I believe that most of the fruits that will be lost would have been small. Certainly the bushes look a good deal better for the treatment, which can hardly fail to stimulate a certain amount of growth. I think I have fairly well proved, however, that Boskoop Giant is really the only variety worth growing on my soil, in spite of its being more liable to bud mite than it used to be. When the plantations were young, and nearly all interplanted with Black Currants of the variety mentioned, the bushes were never pruned after they reached the fruiting stage, and yet they continued cropping and growing well until hopelessly affected by bud mite. Finding the best variety for the locality is most important with Black Currants.

SPRAYING COX'S ORANGE PIPPIN APPLE.

In preparation for the coming campaign against scab, I am trying to find out whether Cox's Orange Pippin Apple can safely be sprayed with Bordeaux mixture of full standard strength (8-8-100) when at the pink bud stage. If any gardener or grower can tell me this from actual experience I shall be very grateful. I dare not spray this variety with Bordeaux mixture of any strength after blooming. It can sometimes be done with safety, but is always too risky. I know that it will stand a good deal more before blooming, although anyone who has not tried it might imagine that the contrary would be the case. It seems curious that the tender young leaves surrounding the bloom should be less vulnerable than the mature foliage, but such is undoubtedly the case. *Market Grower.*

VEGETABLE GARDEN.

PEAS.

THE varieties of culinary Peas are so numerous that the grower is wise who relies on those sorts which he has proved to do well in his particular soil and district, and in this respect the numerous names that have been given to very similar varieties is most puzzling and causes the small grower much confusion. Peas do well on stiff and calcareous soils, and also light soils when liberally manured. They need potash, lime and phosphates, also a constant supply of moisture. On poor land they give a poor return, in fact, food and moisture in abundance are very necessary to obtain good crops of Peas. The ground should be prepared in the autumn, and if it is trenched, so much the better. Heavy manuring is not needed for the earliest crops, but for late Peas, trenching the soil and incorporating with it plenty of decayed manure and vegetable refuse always pays, provided the manure is placed below the top spit. Early Peas should be grown on ground that was trenched and heavily manured for a previous crop. In the case of late summer and autumn Peas, unless the land has been treated liberally and is good in every respect, the Peas soon lose their colour and become infested with maggots and mildew; the failure is then complete.

I do not resort to watering Peas even in a hot, dry period, but prefer spending half the time and labour in preparing the ground properly at the right season, for this gives much more satisfactory results than watering.

The rows for late Peas should always be prepared at the same time as the early ones; the manure has then time to become in a fit condition for the roots. In very dry weather the drills should be soaked with water before sowing the seeds, and the latter covered with dry soil, the rows to be mulched with half-decayed manure later. By allowing a distance of about eighteen inches on each side of the row and making the drills about three inches wide, in conjunction with a thorough preparation of the soil, watering will be rendered unnecessary even in the driest weather.

Mid-season and late Peas are so valuable that everything should be done to help the crop to pass through its most difficult periods. Large Marrow Peas should be allowed plenty of room for branching out, and be sown thinly—about three inches apart. The rows should be isolated from other tall-growing crops. Where sticks are plentiful, tall, main-crop sorts are best for planting as they are most prolific, but dwarf Peas are universally desired for small gardens on account of their quick returns and the small amount of space they occupy. The rows may vary from two feet to three feet apart; nothing is gained by close sowing, as the rows may be intercropped with Lettuces and other similar crops. The seeds may be sown from November to March.

Wrinkled Peas are usually more tender than tha round-seeded sorts, and do not germinate so well as round Peas, nor does the germinating power of the seeds last so long. Early Peas may be produced in various ways; success generally follows the sowing of an early, dwarf variety at the foot of a south wall, but one or more sowings of quick-growing varieties should be made on a sheltered border, prepared especially for the purpose, and where protection may be provided whenever necessary. On a warm soil and in a good season the plants of an early sowing on a south border give pods for use about the end of May, whilst pods from those sown on less sheltered borders are available early in June. In some seasons the crops from the February and March sowings are not more than eight or ten days behind those of the November sowings, but even a week or ten days advance in cropping is a consideration.

It is a much disputed point amongst good growers whether November sowing has any advantage over one made early in spring, as the latter crop is less subject to injury from mice, birds, insects and damp, and generally proves the most productive. Every endeavour should be made to extend the Pea season from the beginning of June until the end of October. In some seasons exceptionally good Peas may be gathered in November, but such a late crop is mainly dependent upon the season. To maintain a regular succession it is always wise to sow three or four distinct sorts at the same time, as early and second-early varieties sown during February and March will not vary more than a week or ten days in the date of cropping. In April the succeeding crops may be sown so soon as the preceding one is through the ground. Dusting the rows on frequent occasions with soot is to be recommended, and a little soil should be drawn up to the rows so soon as the Peas are well through the ground. The sticks should be placed in position early, filling in between the large sticks at the base with twiggy material to enable tall-growing varieties to ascend, and to protect them from cold winds.

In the trial of early Peas at Wisley in 1920 some well-known varieties failed to justify the awards given them in 1915. To those who have a sheltered position and favour sowing in November, or later if unfavourable at that time, I recommend Superb, Earliest of All and Eclipse in the dwarf section, and Primo, Pilot Improved and Essex Star in the tall section, in the order named.

I do not like omitting William the First, but Essex Star has a better constitution. All these varieties may be relied upon to mature pods the last week in May or first week in June, according to the season.

For spring sowing we have choice of many dwarf varieties, but I would again put Laxton's Superb first, especially for growing in cold soils. We have Reading Wonder, Little Marvel, Laxton's Progress, Pioneer, Hundredfold, and Excelsior to follow, and of the newer varieties Kelvedon Wonder, Giant Stride and Marvellous Improved, all of which are worthy of extended trials. If sown in February or early in March, all the above sorts may be regarded as first-earlies, and the crop will be ready the first or second week in June. Taller varieties suitable for this sowing, besides those named, are Prosperity, Electricity, First of All, Express, Early Morn and Bedford Champion, the last a grand Pea, superior to Gradus. Second-earlies and main-crop sorts include, in the dwarf section, Senator, Victory, Beauty and Yorkshire Hero, to supplement those already recommended. Tall varieties include Admiral Beatty, Stourbridge Marrow, Alderman, Duke of Albany, Reliance, Peerless Marrow and Lancastrian. These varieties sown during April and May will take about thirteen or fourteen weeks to mature their pods in an ordinary season. New main crop varieties of great merit are King George, King of Peas, Sharp's Renown, Northern Record and Premier. Late varieties of merit, which should not be sown later than the second week in June, are Ne Plus Ultra—this variety has been subject to mildew in recent years, Omega, August Monarch, Captain Cuttle, Late Queen and The Gladstone, the last an excellent cropper and possibly the most reliable late Pea in cultivation.

Some of the hardy early varieties are worth growing, being especially good in a favourable season on a warm border. Much, however, depends on the weather of September.

There are many other varieties that will compare most favourably with the above selections, and different growers may have a preference for some of these sorts, yet those recommended are good growers, good croppers, and give Peas of excellent table quality. *F. Jordan.*

FORCING LETTUCE.

THE variety of Lettuce called Grand Rapids in America was grown at Wisley in the trials under glass in 1924-5, along with another of the same type—known variously as Tomhannock, Prize Head, and American Gathering—also largely grown in America, and it has been grown in other ways on other occasions. Tomhannock is red-tinged and white-seeded. Grand Rapids, wholly green and black-seeded. Both are very large Lettuces of good quality, tender, crisp and rather bitter in flavour. Both gave a very fair account of themselves under glass, but they belong to a group that has not found favour in British horticulture up to the present for instead of making hearts (as all well-conducted Lettuces should do) the centre of the mature plant is occupied by a tightly-bunched group of frilled and blistered leaves, not overlapping as in the well-known hearting varieties. Grand Rapids is known and grown by a few in this country under the name of Winter Gathering.

That excellent Lettuce for growing under glass which shared with the new Dutch variety Nunhem, the distinction of F.C.C., called Gotte a Graine Noire in the country of its origin, but known here as Early French Frame, is of the normal hearting type. It is much smaller than Grand Rapids, and neither It or Nunhem is suitable for out-door cultivatioun. Both, however, are highly to be recommended for this special purpose.

As your note (p. 74) states, Stanstead Park and Hardy Green Hammersmith, old Cabbage varieties, both well held their own out-doors in the trials of autumn-sown Lettuces, but both were greatly surpassed by Nunhem and Early French Frame under glass. *Fred J. Chittenden, Wisley.*

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents].

Frost and Insects.—In reply to Mr. G. C. Johnson, p. 68 after twenty-three degrees of frost on the 16th ult., and a consecutive frost of about 115 hours, I found numbers of the small black slug and the brown slug among and under the leaves of Lamb's Cress, growing on a south border in the open. If my memory serves me right, there was not any perceptible decrease in the insect world in the summers following the great storms of 1895 and 1917. Concerning snails or slugs, there is a small black one in this district which will take a lot of beating for mischief, and is at all times very plentiful. *J. E. L.*

Awards at the Royal Horticultural Hall.—As a fairly regular visitor to the fortnightly meetings of the R.H.S. at Vincent Square, I have often been puzzled by the way awards are made to certain exhibits. The *Book of Arrangements* states that the "Gold Medal is awarded to exhibits of special excellence," but it conveys no indication of how this is to be interpreted. It must be extremely difficult for the Council or a committee to decide when an exhibit is worthy of a gold medal, and it would almost appear that the standard varies. I could understand that two exhibits of Orchids at the meeting of January 12 were worthy of a gold medal, but could not understand why the fine exhibit of vegetables failed to receive similar recognition. In it, I counted over 120 dishes of distinct sorts, and although no one would pretend that the specimens were as perfect as if shown in September or October, I thought they were as perfect as any one could produce them in

January. Trade exhibitors may or may not trouble themselves about R.H.S. awards at these shows: if they do not, then surely it is time the Council ceased to make awards to their displays, especially as the members of the horticultural press have usually made their notes and left the hall before the Council has issued the list of awards. *A Fellow.*

Memories of Dr. William Bateson.—A correspondent who desires to remain anonymous, writes: "Though perhaps a little outside the scope of an obituary notice in this paper, I feel that no picture of the late Dr. William Bateson would be complete without a reference to his very human enjoyment of the good things of life which lay outside his work. A new artist, or that rarer thing, a new joke, had his quick and undivided attention and the reward it deserved. The writer remembers his delight when he first came upon the remarkable collection of Samian pottery in the Reading Museum, or again at a recent agricultural show when a collection of local handicrafts captured his attention for some time. A quick glance showed him which things were worthy of closer inspection, and he studied for some time a silver bowl, making suggestions to the designer. A little further on a mechanical nightingale in a cage was given the same fresh attention. It was amusing to sit near him while a game, perhaps of croquet, was in progress. The players would be admonished, cheered and jeered at, and in the midst of it all he would turn to a neighbour and say, "Yes, it is the question of inter-sterility we want to get at." It was this almost boyish zest that made it possible for him to turn from animals to plants so soon as Mendel's work was re-published, and in a very short time he got a good grasp of many branches of horticulture, and even appeared as a witness in a famous law suit when the identity of Gradus Pea was in question. Though his interest was primarily scientific—an endeavour to get at the laws beneath the appearances—one noted a certain satisfaction when some fact of practical utility emerged as a bye-product. Like all men absorbed in their work, Bateson was a little difficult of access a very natural protection; but to those who knew him better he was a constant source of delight. His knowledge and love of art, his quick eye for human weaknesses and a constant sense of humour, made the Bateson of private life a very different person from the eminent scientist lecturing before a learned society. His view of horticulture was never doctrinaire, and he realised that in dealing with things in the mass, such for instance as seed-growing, it is impossible to expect the accuracy which the laboratory demands. Horticulture is the poorer by his loss, and those who knew him cherish the memory of a great man who showed that wisdom and humour may dwell together in amity."

Onions.—On page 86, Mr Roy indicates an alternative method of Onion culture to the one I recommended in my note (page 34). The statement that to pot off the seedlings into thumb pots "is quite unnecessary" is very definite. It seems to me that many things which are quite unnecessary may be desirable in order to attain the best results. Such was my object when I penned my note, and I maintain that the potting off process gives a higher yield of produce than any other method of cultivation. I have proved it in practice. It is rather remarkable to learn that one can safely feed the Onion crop at any time. The information abolishes the need of any further teaching in matters of plant nutrition. My experience has been that "thick neck" is liable to develop if feeding commences too early, and second growth supervenes if feeding is continued too late. Though the nomenclature of vegetable varieties is somewhat confused, I have never considered that Premier and Ailsa Craig were synonymous. In my judgment the two varieties are distinct in habit of growth and shape of bulb. There is a resemblance between Ailsa Craig and Cranston's Excelsior, in fact, some strains of the two varieties appear to be synonymous. *Geo. H. Copley, N.D.H.*

SOCIETIES.

BRITISH MYCOLOGICAL

A MEETING of the above Society was held at University College, London, on January 23, with Dr. G. H. Pethybridge, President, in the chair.

The first paper was by Mr. W. M. Ware, who gave an account of Pseudoperonospora Humuli and its mycelial invasion of the host plant. A characteristic of downy mildew or "spike" disease of the Hop is the production of "spikes"—arrested growths from both the rootstock and the main bine. Continuous observation and investigation of the disease were made throughout the growing season of 1925, and nursery sets were examined during the early winter. It was found that the mycelium of the fungus may overwinter in the underground parts of the host, and though the mycelium found has not been definitely connected with its fruiting stage, there is little doubt of its identity. The inference is that in early spring it probably invades developing buds, and either overwhelms the young shoot, producing a basal "spike," or is carried by the rapidly elongating bine close behind the growing point. In the latter case the mycelium may be carried up to a considerable height in its entirety, or small quantities may be deposited at nodes during the rapid growth of the bine: thus we could account for diseased laterals at isolated nodes and terminal spikes at any height from the ground. Actual transference of the mycelium has not yet been observed, however, and early external infection may prove responsible for some or perhaps all of the spiked growths.

An account was given of the discovery and investigation of the internal mycelial invasion of the Hop plant. Mycelium is present within the cortex and pith of the stem of "spiked" growths from the rootstock, and is also present in one-year-old portions of the rootstock. In longer bines with terminal or lateral "spikes" the mycelium is present within the bine but is not necessarily continuous, and healthy intermediate nodes and internodes may be found. The fungus has not been found at the base of such longer bines. The mycelium is present in the winter not only in the pith and cortex of nursery "sets," but it has also been found in the cortex of the roots. Oospores occur plentifully in the pith of terminal and lateral spikes and within the bracts and bracteoles of the Hop "cone."

Kodak, Ltd., then demonstrated the Eastman Colorimeter. The instrument affords a basis for accurate colour measurement. Neutral light filters modify the intensity of light passing through standard comparator filters to equal that on the colour to be tested. Standards are then modified until the colour in the two halves of a visual field, one of which is the object to be tested, agree.

Mr. B. Barnes followed with some preliminary observations of the physiology of Lachnea. A species of Lachnea grown on media containing nitrogenous material with a low carbohydrate content, gives the conidial, Acmosporium, stage, followed by the apothecial stage. On media with more carbohydrate the conidial stage appears occasionally, followed by secondarily formed apothecia. The conditions which determine the appearance of one or the other stage are being analysed, and the relation between the composition of the media and the development of mycelial fusions. As ascospores of Lachnea have not been germinated, it is thought that the Acmosporium-Lachnea combination, which shows no sexual phenomena, is an ascomycete with a hyphomycetous bias.

After lunch, Mr. Chastin Chapman, President of the Royal Microscopical Society, spoke on the need for a national institute of microbiology. The study of the precise way that living organisms exercise their vital activities stands out prominently from the problem of bio-chemistry. The inefficient clumsiness of laboratory methods of synthesis compared with natural methods is striking, and it is by closer study of the living cell that the chemist may hope for a new era of industrial organic chemistry.

There are many industrial processes in which micro-organisms are the active agents. Glycerine is produced on a large scale by the fermentation of sugar, moulds are used for the saccharification of starch. Vinegar, lactic, butyric and other acids are manufactured by fermentation processes, and micro-organisms are also important in agriculture, in dairy work and in the treatment of sewage. Many biological industries in this country, representing a large amount of trade, have made little or no process since their beginning, and it is to be hoped that industrial micro-biology may share the present enthusiasm for scientific research. In 1923 a joint meeting of the Society of Chemical Industry and the Biochemical Society supported a scheme for the founding of a national institute of microbiology. Such an institute would provide for research in the industries in which micro-organisms are concerned, it would serve as a centre for specialised training in microbiology and afford opportunities for instruction of technical employees engaged in biological industries. In addition, it would house a complete collection of pure cultures of industrial micro-organisms and supply these as required in large quantities for industrial purposes and generally serve as a home for British industrial microbiology. Such an institution with the right men behind it would quickly be self-supporting, but to become successful it would need to be a separate national institute and not a department of any existing teaching institution.

A resolution was carried unanimously that "The members of the British Mycological Society are of the opinion that it is most desirable that a National Institute of Microbiology should be established in this country."

Mr. G. Tandy then gave an account of the cytology of Pyronema domesticum, Sacc. In the fertilisation of this species the nuclei fuse in pairs in the oogonium, but haploid and diploid nuclei are found in the ascogenous hyphae. The definitive nucleus of the ascus is sometimes diploid and sometimes tetraploid. The nuclei of the bi-nucleate stage are sometimes diploid and sometimes haploid as are the nuclei at the quadri-nucleate stage, but in no case has a diploid spore nucleus been seen. It is suggested that the fusion in the oogonium may miss, but that the double fusion is compensated for by two reductions.

The last contribution was by Mr. J. Ramsbottom, with the title Fragmenta Mycologica V. This included an account of a visit to the veteran mycologist of the Trentino, Abbé G. Bresadola, and an exhibit of photographs; also a display of a large number of air photographs which had been loaned by Mr. O. G. S. Crawford, Archaeologist to the Ordnance Survey, the photograph showing "fairy rings" of various sizes and stages of fusion.

FÉDERATION HORTICOLE PROFESSIONNELLE INTERNATIONALE.

THE registration of the following novelties have been submitted to the International Bureau of Registration:—Gladiolus Margaret Lewtas: a very early flowering variety with spikes thirty-six to forty-five inches tall, containing some twenty or more blooms of cerise-red colour.

Gladiolus Sarah Wood:—A large, bright red variety with a silvery sheen on the inside of the petals. The stem is straight and vigorous. Both these were raised by MISS NELLIE M. STOCKFORD, Woolwich Street, Guelph, Ontario, Canada

Rose Agnes.—A cross between Rosa rugosa and Persian Yellow, the habit, texture and colour of the leaves resembling R. rugosa. The flowers are double, of pale amber colour, fragrant, and develop early, but the variety only blooms once during the season. Raised by the late Mr. W. Saunders, Ottawa, Canada.

Gladiolus Lauretta Peer—A seedling variety, the parentage being unknown. The colour is light purple, and deep purple in the throat, the mid-vein on the petals being light. The spike usually carries about fifteen flowers which are closely arranged on the inflorescence.

Gladiolus John Wesley.—This seedling has three-cornered segments of salmon-pink colour suffused with deep red inside, the mid-vein being lighter. The flowers are about five-and-a-half inches across, sixteen to seventeen being borne on a vigorous, erect spike. Both raised by Mr. J. WESLEY PEER, Lorne Park, Ontario, Canada.

Strawberry Scugog.—A cross between Rango (a seedling raised by Mr. Crawford) and Bubach. The variety is a heavy cropper. The fruits are of a good colour, have very little core, a solid centre and fair flavour. It is a vigorous grower. Raised by Mr. CHAS. BYRON CRAWFORD Cooksville, Ontario.

ROYAL GARDENERS' ORPHAN FUND.

THE Annual Meeting of The Royal Gardeners' Orphan Fund was held on the 3rd inst., at Simpson's Restaurant, Strand. Mr. D. Ingamells, chairman of committee, presided, and those present included Mr. J. F. McLeod, Mr. D. Campbell, Mr. H. J. Jones, Mr. C. H. Curtis, Mr. J. Gregory, Mr. J. Cull, Mr. J. M. Bridgeford, Mr. D. Swain, Mr. R. B. Leech, Mr. J. Wort, Mr. W. Howe, Mr. G. F. Tinley, Mr. A. Dawkins, Mr. A. Harris and Mr. A. C. Bartlett (Secretary). After the notice convening the meeting and the minutes of the previous annual meeting had been read, the chairman called upon the secretary to read the report of the executive committee for 1925, of which the following are extracts :—

EXTRACTS FROM THE REPORT OF THE EXECUTIVE COMMITTEE.

Your committee are most pleased to be able to report that Her Majesty the Queen has graciously consented to become the Patron of the Fund.

Your committee offer grateful thanks to all the subscribers and donors for their continued support which enables them to extend the relief to the orphan children who have been so unfortunate as to be deprived of their fathers. In addition to the customary allowances it has thus been made possible for the committee to continue the allowance for a further twelve months to several of the children who have won scholarships at their schools. In these cases the head-masters have written giving their scholars exceedingly good reports, and have expressed their unqualified opinions of the value the extended education will be to the children individually, and, it is hoped, to the country in the near future. In every instance the widowed mother has made great sacrifices in order to give her child the best possible start in life, but it has been fully evident that her hopes and desires could not have been realised without the help she receives from the Fund.

As will be seen in the Statement of Accounts the total income of the Fund, from all sources, during the past year, including the balance from 1924, amounts to £5,162 2s. 11d. This includes legacies of £500 from the late Sir Harry J. Veitch, and of £50 from the late Mr. J. P. Jones, of Reading, and the repayment of the Great Indian Peninsula Railway Stock held by the Fund. The investment of the legacies, etc., has enabled the committee to do something towards restoring the Invested Funds to their pre-war position. Your committee would point out that all legacies must be invested in approved stock and only the interest is available, and to carry on its work the Fund has to rely principally on annual subscriptions and donations.

The Annual Festival Dinner, which was held at the Hotel Victoria last May, again proved to be very successful, and your committee would offer their sincere thanks to Sir Alfred Mond, Bt., M.P., who very kindly presided and made a donation of one hundred guineas.

Your committee again wish to acknowledge with heartiest thanks the valued contributions from the following gardening associations during the past year. The Altrincham and District Gardeners' Improvement Society, Croydon Horticultural Society, Parkstone Gardeners' Association, Leeds Paxton Society, Royal Caledonian Horticultural Society, Croydon Chrysanthemum Society, Egham and District Horticultural Society, Wimbledon Gardeners' Mutual Improvement Society, Bradford Paxton Society, Dumfries and District Horticultural Society, Bournemouth and District Gardeners' Mutual Society, Sevenoaks Gardeners' Society and the West Kent Chrysanthemum Society.

Considerable amounts were collected by Mr. W. Auton, Pyrford Court Gardens, Woking; Mr. T. H. Cook of the Royal Gardens, Sandringham; Mr. F. C. Stainsby, lately of Brocklesby Park Gardens, Lincolnshire; Mr. T. Pateman, Brocket Hall Gardens, Hatfield; Mr. Wm. Rowe, Squerreys Court Gardens, Westerham; and Messrs. Wm. Thomson and Sons, Clovenfords, chiefly by means of concerts and other entertainments. Your committee desire to record their great appreciation of the work thus done on behalf of the Fund.

In addition to the loss the Fund has sustained through the death of its Royal Patron, your committee is deeply grieved to have also to record the deaths of Arthur W. Sutton, Esq., who was long a valued vice-president, and Whitpaine Nutting, Esq., who for many years was a member of the committee and a most generous supporter of the Fund.

The chairman moved the adoption of the report and balance sheet, which he stated was very satisfactory, and he congratulated the Fund on reaching the happy position of being able to give a little additional help to those orphans that needed it. Mr. C. H. Curtis seconded the adoption of the report, and in doing so, stated that the balance sheet showed an excellent state of affairs; he congratulated the committee on being able to place on the Fund all the candidates seeking election.

The secretary referred to items in the balance sheet, in which it was shown that subscriptions amounted to £256 7s. 9d., and donations to £406 1s. 2d. The proceeds of the annual festival dinner totalled £749 13s. 0d., dividends on stock, interest, etc., came to £386 8s. 4d., and together with legacies, and balance from 1924, the total income amounted to £5,162 2s. 11d. The principal payments were £1,037 15s. 0d. in respect of children's allowances, secretary's salary and establishment charges, £231 18s. 10d.; printing, stationery and postages, £117 9s. 11d. Both the report and balance sheet were adopted without further comment.

Reference was made to Her Majesty The Queen graciously consenting to become Patron of the Fund, and in this connection the meeting offered sincere thanks to Lord Lambourne for his kindness in this matter, and desired his lordship to convey the Fund's loyal and dutiful thanks to Her Majesty. Sir Alfred Mond was elected vice-president of the Fund, and a hearty vote of thanks passed to him for presiding at the last annual festival dinner.

The election of officers was the next business; Mr. E. Sherwood was re-appointed treasurer; the retiring members of the committee, Messrs. A. Dawkins, J. E. Dixon, R. Findlay, H. J. Jones, D. Campbell, G. Reynolds and F. C. Stainsby, were re-elected, and Mr. Herbert R. Nutting elected to the vacancy caused by the death of Mr. Whitpaine Nutting. The retiring auditor, Mr. R. A. Witty was also re-elected. The chairman proposed the election of Mr. A. C. Bartlett as Secretary and said his work on behalf of the Fund during the past year had been very satisfactory and that he had proved an efficient and sympathetic secretary. This concluded the formal business, and the meeting next proceeded to the election of seven candidates. There being no necessity to take a poll the whole of these orphans, whose claims had been considered by the committee, were elected by resolution; the names of the children were published in our issue for February 13, p. 109. A vote of thanks to the chairman concluded the proceedings.

READING AND DISTRICT GARDENERS'.

THE first fortnightly meeting of the spring session was held in the Club Room, Abbey Hall, on Monday, the 25th ult., when there was a crowded attendance, presided over by the newly-elected Chairman, Mr. F. J. Green.

This meeting was set apart for the reading of essays in a competition for young members, and the innovation proved a great success. In the spring of last year, Mr. Councillor T. Waldron offered to give prizes to encourage the younger members to take a deeper interest in the work of the Association by giving lectures at the meetings. The papers read were most practical, and the cultural details excellent. Great interest was manifested by the members and Mr. H. F. Simmons, one of the oldest members of the Association, was so impressed by the educational value of the competition that he asked permission to double the value of the prize money, whilst Mr. Waldron offered to give similar prizes again next year. At the close of the reading of the papers a vote was taken as to the merits of the different subjects, with the following result:—First prize, "Lawns from Seed," Mr. G. F. Drew; second prize, "Garden Pests," Mr. J. Drew; third prize, "The Culture of the Japanese Chrysanthemum for Exhibition," Mr. S. A. Pearce; and fourth prize, "Sweet Peas and their Culture for Exhibition." Congratulations were tendered to the writers, and were replied to by Mr. G. F. Drew and Mr. S. A. Pearce, thus bringing to a close a most interesting and enjoyable evening.

Mr. T. C. WAITE, Verona, Basingstoke Road, staged several varieties of Apples, all in good condition, to which the judges directed special attention.

A LARGE attendance of the members assembled on Tuesday, the 9th inst., under the chairmanship of Mr. Frank E. Moring, to hear a lecture on "Sweet Peas" by Mr. E. R. Janes, of Messrs. Sutton and Sons. The lecturer claimed for the Sweet Pea that it was the most beautiful of all annual flowers, and proceeded to give the fullest details of its culture for exhibition and garden decoration. The first and most important question, he said, was the time of sowing, and in his opinion, autumn sowing was preferable to spring sowing, as the former gave a longer period for root development, and the seedlings were ready for planting out at the end of February or beginning of March. An interesting discussion followed the lecturer's remarks. Among the varieties recommended were Avalanche, Constance Hinton, Black-seeded Cream, Youth, Hébe, Picture, Charming, Mammoth, Royal Scot, Warrior, Powerscourt and Mrs. Tom Jones. A series of lantern slides showing a year's work in Sweet Pea culture, from seed-sowing in September until the plants finally pass out of flower, added greatly to the interest of the lecture. The only exhibit was from Mr. G. CLARK, Dyson's Wood Gardens, who staged several fine sticks of Rhubarb, to which an Award of Merit was given. Seven new members were elected.

ROYAL CALEDONIAN HORTICULTURAL.

ANNUAL MEETING.

THE annual general meeting of this Society was held in Dowell's Rooms, George Street, Edinburgh, on the 13th inst., with Mr. Fife, the retiring president, in the chair. The report by the Council stated that the Society has had a satisfactory year, and that the International Show was a great success, financially and otherwise. There was, however, a considerable deficit on the Spring Show, and it had been decided to discontinue this meantime.

Mr. A. D. Richardson submitted the financial position of the Society to severe criticism. He pointed out that while there was a steady increase in the number of admissions to membership on the 5s. scale, the numbers on the higher scales were either decreasing or practically stationary, and that since the incorporation of the Scottish Horticultural Association with the Society in 1921, the average subscription per member had decreased from approximately 9s. to 8s. last year. There was a deficit on the revenue and expenditure account of £52 4s. 2d., and, with a sum of £366 19s. 11d. due to sundry creditors at the close of the financial year, the deficit on the current year's account would be over £450. Where was this to come from? It was quite impossible to run a society such as this on a 5s. subscription, and hopeless to try to exist on show surpluses. The only source from which deficits could be made good therefore was the funds, which at present stood at £864 12s. 4d.

Mr. Richardson moved the adoption of the following motions, of which he had given notice: (1) That, in order to afford members residing in country districts an opportunity to attend, in future the annual general meeting of the Society be held in the afternoon instead of the evening, as was the practice prior to 1921; and (2) that at least two of the vacancies in the Council be filled annually by members residing elsewhere than in greater Edinburgh, and that they be nominated by the Council. These motions he submitted, he said, as an act of justice to two-thirds of the members of the Society who, owing to the impossibility of attending at the inconvenient hour (7 p.m.) to which the annual general meeting was now held, were prevented from taking any part in the business of the Society. The motions were, however, defeated by substantial majorities.

Mr. Richardson also moved that the Council resume negotiations with the Board of Agriculture for Scotland on the scheme for the suppression of plant pests which was submitted to it by the Society in 1923, upon which a committee of the Council, of which he was a member, with two co-opted members, spent much time, and regarding which the report by the Council stated that nothing more was likely to be heard of from the Board. The motion, however, failed to find a seconder, and he warned the Council that, after the assurance the committee received from the chairman of the joint meeting of the committee and the Board's representatives that the Board had decided to set up test stations, the action of the Council in endeavouring to induce the Royal Horticultural Society to come into Scotland to do so, if persisted in, would meet with strenuous opposition outside.

Lord Elphinstone was re-elected honorary president, and the other vacancies were filled as follows:—President, Mr. W. J. Thomsons, Vice-president, Mr. J. H. Alexander: Councillor: Messrs. R. L. Scarlett, W. Fife, R. L. Harrow and E. P. Laird.

Votes of thanks to the retiring office-bearers and the chairman concluded the meeting.

Obituary.

Valère Bouckenooghe.—The many English friends of this renowned Belgian horticulturist will grieve to learn of his sudden decease at Ypres on February 9. Mons. V. Bouckenooghe was sixty years of age and remained at work until the end. When a young man, he went as a student gardener to the Royal Botanic Gardens, Kew, leaving in 1892. He later worked for a considerable period in the Belgian Congo, and for his services there was awarded the Décoration Spéciale Agricole of the Second Class. Returning to Belgium, he became interested in commercial work, and was well-known as the Managing Director of a large and successful nursery established at Ypres. Grapes, Carnations, Arum Lilies, Lilacs and foliage plants were grown on a considerable scale. In one season twenty-five tons of Grapes were sent from the establishment to Covent Garden; in the early days of the Great War the first British battalion to enter Ypres was given temporary shelter in his largest vinery, which covered one acre. Shortly before the commencement of hostilities, Mons. Bouckenooghe conducted a party of British horticulturists around the town pointing out features of interest. During the distressful months which followed hostilities, Mons. Bouckenooghe and family were forced to leave the war zone and found refuge in England. He frequently spoke of the kindness they received during their sojourn in England from many friends, especially from Mr. and Mrs. Brunton, at Burnley. On their return to Ypres they found their house in ruins and hardly a trace left of the once prosperous nursery. Conditions did not permit of the business being recommenced, and Mons. Bouckenooghe's services were required as Commissaire d'Etat in connection with valuation of land and property for war damages. Quite recently he received the honour of appointment as Chevalier de l'Ordre de la Couronne de Belgique. He was the first honorary member of the British Club at Ypres, and by his kind and generous nature won the esteem and gratitude of the British Colony resident at Ypres since the war. He assisted them in their work and difficulties and frequently joined in their recreation. Many societies, both Belgian and British were represented at the impressive funeral service on Friday, February 12. Our deep sympathy is extended to Madame Bouckenooghe who is a real friend of the British people, and to the two sons, the elder of whom follows the horticultural profession with Mr. Engelmann, at Saffron Walden, the younger being on military service in Belgium.

ANSWERS TO CORRESPONDENTS.

Carnations Diseased.—*W. A.* The trouble is apparently what is known as stigmonose, caused by the puncture of some sucking insect, probably, in this case, thrips; if indoors, the species likely to be causing the damage is Heliothrips haemorrhoidalis; if out-doors, several species might be concerned. The spots, at first pale yellow in colour, turn a purplish-red later. The tissues of the leaf collapse, turn yellow and wither, and the plants may become stunted. If the plants are indoors, fumigation with hydrocyanic acid would be effective; out of doors, spraying with nicotine and soap solution is best, though many gardeners rely on regular spraying with ordinary water. Frequent stirring of the soil around the base of the plants is also said to help keep these pests in check.

Forthcoming Shows.—*A. E. B.* There is a list of horticultural societies with names and addresses of secretaries in our *Horticultural Directory* (latest edition 1924, price 2/-, post free), but if you desire the dates of the shows to be held in 1926, we can supply this information, also with the names and addresses of the secretaries, on typed sheets, for the sum of 2/7, post free.

Lime-Sulphur Wash.—*G. P.* The home-boiling of lime-sulphur wash is a messy business, and when it is done one cannot really tell what dilution to use without having a hydrometer to test the specific gravity of the concentrated liquid. An iron "copper" with a fire under it is required. Suitable quantities would be 42 lb of lime; 56 lb. of sulphur, and 25 gallons of water. The lime, which must be in lumps, is placed in the copper, slaked with a little water first, and then the rest of the water added. The contents are now brought to the boil, and kept gently boiling while the sulphur is added. This should be done gradually, in small quantities at a time. The mixture should boil for an hour after all the sulphur has been added. A little water will have to be added to make up for that lost by evaporation. As home-boiled lime-sulphur is always weaker than factory-boiled, you would no doubt be safe in using it for winter spraying at a dilution of one part in twelve.

Names of Fruit.—*J. C.* 1, Adams's Pearmain; 2 and 11, Northern Greening; 3, Broad Eyed Pippin; 4, Herefordshire Pearmain; 5, Mabbot's Pearmain; 6, Hormead Pearmain; 7, Ribston Pippin; 8 and 10, Melon; 12, Fearn's Pippin. *W. T. J.* 1, Ashmead's Kernel; 2, Nancy Jackson. *A. P.* Harvey's Wiltshire Defiance.

Names of Plants. *M. C.* 1, Sequoia sempervirens; 2, Cryptomeria japonica; 3, Pinus Strobus; 4, Abies lasiocarpa; 5, A. pectinata; 6, Cupressus pisifera var. plumosa; 7, Thuya plicata; 8, Cupressus Lawsoniana var. juniperina; 9, C. L. var. Fraseri; 10, C. L. var. aurea; 11, C. L. var. erecta viridis.

REPLY.

I do not think your correspondent *T. C.* need be afraid of rabbits eating his Ericas planted in woodland. I have planted some thousands of all kinds of Heaths during the past few years in a wood in which rabbits are numerous. In exceptionally hard winters they might do a little damage to the young shoots, but I have never had occasion to protect any of the Heaths from rabbits, although I have had to do so in the case of young Scots Firs growing in the same wood—even this winter, but not to a great extent—but only while frost was prevalent recently. *Ernest Seaplehorn.*

GARDENING APPOINTMENT.

Mr. Henry Cameron previously at Mertoun Gardens, St. Boswells, as gardener to Major Falconer Stewart, M.C., at Castle Fiddal, Braco, Perthshire. (Thanks for 2/6 for R.G.O.F. Box. Eds.).

Remarks.—Best Daffodils still remain firm in price. King Alfred is exceptionally fine in quality. Sir Watkin, Victoria and Emperor are more plentiful, but Golden Spur is somewhat shorter in supply. The finest blooms are from the Hampton district. Larger consignments of the cheaper grades of Daffodils are being received from Cornwall and the Channel Islands; these are Henry Irving, Golden Spur, princeps and King Alfred. Large supplies of yellow Narcissus Soliel d'Or, Gloriosa, Grand Primo are also arriving from Guernsey and Scilly. The quantities of Tulips have been somewhat shorter during the past week, especially of coloured varieties. Darwin Tulips are increasing in quantity, and their prices are on the down grade. Narcissus ornatus is now coming from several districts, and prices are easier for all grades. Amongst Liliums, small consignments of L. longiflorum, var. formosum are on sale, these being very fine in quailty. The variety giganteum appears to be shortening, and prices were a trifle firmer to-day. The only Roses still available from home growers are Madame Butterfly, Columbia and Richmond. A few small blooms of Sunburst have been received from Holland during the past week. English Violets, Freesias and Snowdrops are arriving in large quantities. Forget-me-nots are good in quality. A few Wallflowers marketed are of very medium quality. Small consignments of Chrysanthemum Cheshunt White, are still arriving in good condition and meet with a good demand. Larger consignments of flowers are now arriving from the south of France; with the exception of Paper White Narcissus, prices are on the down grade, and they fluctuate according to the quality on arrival. Anemones, Ranunculus and Parma Violets are much improved in quality. Some well-grown Freesias are arriving in good condition and they are meeting with a good demand; the stalks are long and the spikes useful for decorative purposes.

GLASGOW.

The tone of the cut flower market was somewhat irregular in the past week, with an easier tendency of prices which reached their lowest level on Tuesday. A moderate recovery, however, took place on Friday, but it did not extend to all sections of the market. Mimosa was very plentiful, and part of the daily consignments from London was unsaleable at 2/6 to 4/- per chip. Lilium longiflorum (Harrissii) declined to 6/-, and Arums (Richardias) to 5/-. Lily-of-the-Valley to 1/- per bunch, while Narcissi were only worth from 1/6 to 2/3 per dozen bunches. Carnations ranged between 3/- and 5/- per dozen, and. Hyacinths sold from 8d. to 1/- for 3's. Although Tulips were in shorter supply, values generally moved in a downward direction, which is reflected in the following quotations: Bartigon, 1/3 to 2/-; William Pitt, 1/3 to 1/9; Farncombe Sanders, 1/3 to 1/7; Le Notre, 1/3 to 1/6; W. Copland, 1/- to 1/3; Ibis, 1/- to 1/2; Couronne d'Or, Flamingo, Tea Rose and Prince of Austria, 10d. to 1/1; Brilliant, 9d. to 1/-; Murillo and La Reine, 8d. to 10d. Prices of Daffodils also dropped, King Alfred making 2/- to 2/4 per dozen; Golden Spur, 1/- to 1/2; princeps, and Sir Watkin, 11d. to 1/-; and ornatus, 5d. to 7d. per bunch.

There is not much of importance to report in the fruit market, business being moderate in dimensions and values steady. Jaffa Oranges advanced to 22/-, and first arrivals of Californian Navel Oranges averaged 35/-. Valencia Oranges and American Apples showed no movement one way or the other. Naples Lemons, 300's, sold at 15/- to 18/-, and Palermo at 12/6 to 15/-, while Palermo Bitter Oranges returned 8/- for 200's. South African Peaches fluctuated between 5/6 and 7/6; Pears, 4/6 to 6/6, and Plums, 5/6 to 9/-. Pines were worth 5/- to 5/6 each. Prices for Gros Colmar Grapes remained steady, English at 3/- to 3/6; Scotch at 2/6 to 3/6, and Dutch at 1/8 to 2/6.

In the vegetable department, Cucumbers sold at 1/- to 1/6 each. Teneriffe Tomatos, 30/- to 38/-; Dutch Carrots, 7/- per cwt.; Syboes, 7/- to 8/- per dozen bunches; Lettuces, 1/6 to 1/9, out-door, 3/6 to 4/-; Seakale, 1/8 to 2/-; Asparagus (sprue), 1/- to 1/3; Chicory, 4d.; Endive, 3/- to 4/- per dozen; and Rhubarb, 28/- to 32/- per cwt.

TRADE NOTE.

With reference to the recent activities concerning foreign Apples which have been rendered more or less poisonous by the use of a spray containing arsenic, it may be of interest to note that a considerable amount of business has been placed with Lloyds' Underwriters by various fruit importers. The insurance effected is intended to cover all losses to the assured (and his customers, in respect of Apples supplied by him) in respect of all claims made against him in connection with the sale of American and Canadian Apples, including any litigation, legal damages or prosecutions by local or government authorities, and also indemnifying him against any loss on account of Apples condemned by the authorities. The insurance also covers third party risks, that is to say, claims by persons who have been poisoned by eating Apples supplied by the assured. Premiums are based on the approximate turnover for the last year, and are charged "in full" and not as a percentage. There do not appear to be any general rates at present in force, the rate varying with each individual case. On account of the number of enquiries received, and the fact that only certain underwriters are accepting this business, the rates are hardening daily, and a general rise is expected shortly.

CATALOGUES RECEIVED.

Hurst and Son, 152, Houndsditch, E.1.—Gladioli, etc.; Bamboo Canes, etc. (Wholesale).

T. Smith, Daisy Hill Nursery, Newry.—Seeds of hardy plants.

Clibrans, Ltd., Altrincham.—Indoor and bedding plants; trees and shrubs, etc.; Cyclamen.

John Forbes (Hawick), Ltd., Buccleuch Nurseries, Hawick.—Florists' flowers, hardy plants, seeds, etc.

SCHEDULES RECEIVED.

Taunton Deane Horticultural and Floricultural Society.—Fifty-fourth annual show, to be held in The Park, Taunton, on Wednesday and Thurdsay, August 11 and 12.—Secretary, Mr. F. J. J. Stacey, 3, Hammet Street, Taunton.

Reigate, Redhill and District Gardeners' Mutual Improvement Association.—Floral Fete to be held at Batts Hill House, Redhill, on Wednesday, July 7. Secretary, Mr. W. Rose, Hillside, Linkfield Street, Redhill.

The Bermondsey and Rotherhithe Horticultural Society—Spring Flower Show to be held in the Princess Club, Jamaica Road, London, S.E. 16, on Thursday, April 15, at 7.30 p.m.—Secretary, Mr. L. D. Corder, 42, Upper Grange Road, Bermondsey.

Leeds and District Market Gardeners' Association.—Thirteenth Annual Rhubarb Show, Dinner and Smoking Concert to be held at the Griffin Hotel, Leeds, on Saturday, February, 27, 1926.—Hon. Secretary, Mr. S. H. Ramsden, Branlcar, near Wakefield.

Arsenical Sprays and Weed-Killers.

THE question whether the use of arsenical preparations for spraying fruit trees or killing weeds is apt to be attended by results harmful to the life of animals has often been discussed. During the past year it has again been brought into prominence by the discovery of arsenic in not inconsiderable traces on imported Apples. The most recent investigations on the use of arsenic in horticulture and agriculture are those made by Mr. Alexander McCutcheon who gave an account of his observations at a recent meeting of the Pharmaceutical Society of Great Britain*. Mr. McCutcheon, who has made an extensive series of experiments in the use of weed-killers and on the poisonous effects of arsenic on plants, appears to incline to the view that weed-killers containing arsenic have little if any superiority over those which do not. He finds that dry sodium carbonate in a 1—2% solution, or a 5—10% solution of washing soda, suffice to destroy most weeds and he adds the useful comment that if the solution be made up with soapy water its efficacy is increased. We could wish that our own experience confirmed Mr. McCutcheon's conclusions; but although there may be non-arsenical weed-killers as efficacious as those which contain arsenic, it has not been our good fortune as yet to discover them. There can, however, be no doubt that every effort should be made to dispense with arsenical weed-killers, for although the danger which attaches to their use is, as we think, overrated, the existence of the danger cannot, in view of the evidence brought forward in the discussion which followed the reading of Mr. McCutcheon's paper, be denied. For our part we are inclined to believe that if precautions are taken to keep animals, poultry and the like, away from the sprayed area for a short time during the spraying and the drying of the spray, no evil results are likely to follow. Mr. McCutcheon thinks that arsenic to be effective must touch the foliage; but although this may be true there is the curious and well ascertained fact that an arsenical weed-killer is apt to act slowly. The amount of weed destruction that is to be observed immediately after the application of an arsenical weed-killer is small; but in the course of a few days, provided that the weather be dry, the whole area is brown with the dead plants. The cause of this progressive action of the poison is not clear, but probably resides in the fact that traces of arsenic, too small to be detected by analytical means, are actually absorbed by the plant and prove fatal to it. Nevertheless, it is to be hoped that further systematic experiments will be made in the use of non-arsenical weed-killers and we would suggest that the Royal Horticultural Society should institute a series of trials with a view to determining which are the best and safest weed-killers. Sodium chlorate and ammonium chlorate have been used apparently with success, the former on paths, the latter on arable land, and gardeners would be glad to know if by using these substances they could keep their paths clean without undue expense. With respect to the use of arsenical sprays for fruit trees, few gardeners would be prepared to forego the annual application of lead arsenate—in combination with lime sulphur—which enables them to grow clean fruit. Nor do we think that the risks attendant on the use of this spray, if made at the proper time, are other than negligible. If deferred until the Apple blossom is opening the spraying is likely to have fatal effects on bees; but if done early, before the blossom buds have burst, there would appear to be no danger at all. In America there is a tendency to develop spraying into an elaborate ritual and advice is sometimes given to spray several times. The conjecture may therefore be hazarded that the occurrence of arsenic on the imported fruits was due to late spraying. In this country few gardeners or fruit growers can afford to give their trees more than two sprayings; a winter wash and the lead-arsenate spring cleaning. Nor, in our experience, is more than this necessary; indeed, if the winter spraying with carbolinium compounds, now being so generally tried, proves successful, it may be possible to keep our orchards clean with one annual spraying only. Or if that proves impossible it may be found that the spring spraying must be diverted rather to the control of fungous than to that of insect pests, and lime sulphur, undoubtedly beneficial and harmless, may come to be used together with nicotine, for the spring-time spraying. Everyone would like to dispense with such highly poisonous substances as arsenic. It may be possible to achieve this aspiration by using equally efficacious non-arsenical weed-killers and spray fluids, but at the present time it cannot be stated with confidence that the non-arsenical sprays can do all that those containing arsenic are known to do. Alkaloids — as for example those derived from Derris elliptica—may prove ultimately to be the means of absolving us from the use of arsenical sprays. Preparations of this kind are, we believe, already on the market and appear to give excellent results. We, as gardeners, await authoritative guidance based on comparative tests and are prepared to follow the former if the results of the latter are convincing.

The Hooker Lecture.—Dr. A. B. Rendle announced at the meeting of the Linnean Society on February 18, that the next Hooker Lecture would be delivered by Professor Carl Schröter, F.M.L.S., of Zurich, on April 15 next, entitled, "The Swiss National Park and Scientific Researches into its Nature."

The Lindley Library.—Very considerable additions have been made to the Lindley Library during the past few years; in 1925, no fewer than 451 works, presented, purchased or sent to the Royal Horticultural Society for review, have been added to the collection. The sale of the late Mr. C. Harman Payne's library enabled the Society to acquire many rare books and pamphlets, especially on florists' flowers. Mr. Harman Payne was greatly interested in the Chrysanthemum, and a considerable number of his books were on this flower. The Society also acquired a few of his books dealing with floricultural history, including *Le Floriste Francois*, which is stated to be the earliest monograph of the Tulip, and one of the earliest of all floricultural monographs; it was published at Caen in 1654. Mr. E. A. Bunyard, in the *Journal of the Royal Horticultural Society*, vol. LI, part 1, states that a new catalogue of the Lindley Library is in preparation, and this will be looked forward to with interest by all lovers of gardens, and especially students of horticulture. Mr. Bunyard appeals for gifts of old nurserymen's catalogues in which the historian of horticulture, he states, finds "original sources" of the greatest value

The Civil Service Sports Ground. — Last Saturday the Duke of York, in his capacity of President of the Civil Service Sports Council inaugurated, what is claimed to be the finest and largest sports ground in the country. There was no formal opening, but His Majesty the King was present and was attended by several Cabinet Ministers and many other prominent persons. The weather was ideal for an outdoor function and the event attracted a large concourse of spectators. A short fifteen months ago the thirty acres which now comprise this first-rate sports ground along the river bank at Duke's Meadows, Chiswick, were fruit orchards and derelict land. Before the work proper could be commenced it was necessary to demolish an ancient roadway and culverts and drain a sewage swamp, as well as grub up the many fruit trees. This new sports ground has a spacious two-storied pavilion which provides ample dressing rooms for three hundred players and is fully equipped with plunge and shower baths. There is also a dance hall, club room and tea lounge. There are six "cricket squares," one Rugby and four Association football grounds, four hockey grounds, a bowling green, twenty-six grass and ten hard courts for tennis, a net-ball pitch and a running track. Already £30,000 is stated to have been spent, and this money was provided entirely by subscriptions from within the Civil Service.

International Botanical Conference, 1930.—A meeting will be held in the rooms of the Linnean Society on Wednesday, the 10th March, at 3.30 p.m., to consider a suggestion that the Fifth International Botanical Congress should be held in London in 1930, and, in the event of the suggestion being adopted, to formulate an invitation to be submitted to the ensuing Fourth International Botanical Congress at Ithaca, U.S.A. in August next.

---

* Arsenic with Special Reference to its use in Horticulture and Agriculture. *The Pharmaceutical Journal.* No. 2250, Vol. 116. January 30, 1926.

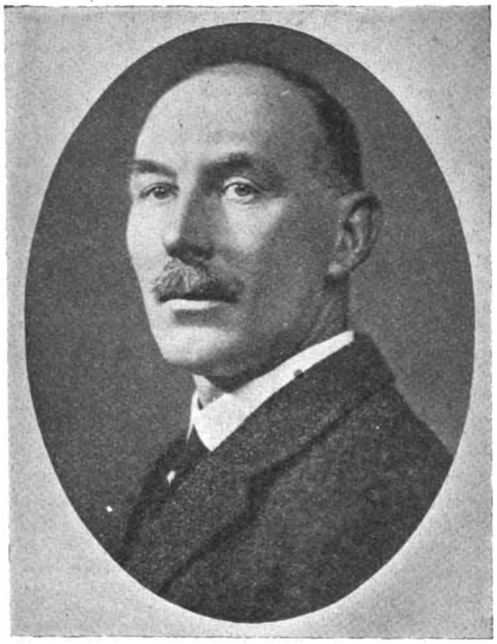
Brussels Trees Threatened.—Dwellers in the beautiful city of Brussels are disturbed at the prospect of losing the fine Plane trees which are at present gracing the Place Loix. It appears that owing to complaints from some of the residents, the municipality is proposing to cut down the trees, but it is to be hoped that such drastic action will not be taken unless it is really necessary.

Trial of Gladioli of the Primulinus section at Wisley, 1926.—The Royal Horticultural Society will carry out a trial of Gladioli of the Primulinus section at Wisley during the coming season. Ten (or five) corms of each variety for trial should be sent addressed to The Director, R.H.S. Gardens, Wisley, Ripley, Surrey, to reach him by March 31.

Horticultural Sale at Wembley.—Messrs. Protheroe and Morris, in conjunction with Messrs. Knight, Frank and Rutley, recently conducted a four days sale of the whole of the ornamental trees, shrubs, plants, garden utensils, and garden sundries at the British Empire Exhibition grounds, Wembley. There was a large attendance each day of both private and trade buyers. Competition was keen and the whole of the lots offered were readily disposed of at prices which may be considered satisfactory. Rhododendrons two feet to three feet high realised from 6s. to 8s. each, and specimens from 30s. to £8 8s. each. English Yews, planted as hedges round the North Garden, realized from 5s. to 6s. 6d. each. A specimen Japanese Maple sold for 9½ guineas. The Delphiniums and the other herbaceous plants found ready buyers. A span-roof greenhouse, fifty feet long, realized £60, and the rectangular York paving stone round the flagstaff realised £75, while the walling stone was keenly sought after.

R.H.S. Scholarships for Young Gardeners.—Two horticultural scholarships have hitherto been available for award on the results of the Royal Horticultural Society's General Examination in horticulture. The older of these was known as the Major Scholarship, and the other as the Knott Scholarship, the latter being awarded out of funds provided by Sir James Knott, Bart., a vice-president of the Royal Horticultural Society. Both were open to men only and were tenable for two years. There were minor differences in the conditions of holding them. This year, and in the future, the scholarships will be offered for award on the results of a special examination designed to test so far as possible the candidate's ability to profit by a course of instruction in technical horticulture. This examination, which will be held in April, will not deal particularly with technical horticulture but with the subjects ordinarily taught in schools. The examination will be open to young men who are not less than eighteen nor more than twenty-two years of age on September 30 in the year of the examination. Candidates must be able to produce certificates of good character, and must be of good health and physique, free from any physical defect that would militate against a career as a gardener, and willing to subject themselves to the rules for students at Wisley. The value of the Major Scholarship is £50 for annum, and that of the Knott Scholarshp, £30 per annum. Both are tenable at the Royal Horticultural Society's Gardens, Wisley, for a period of two years, commencing at the beginning of October in the year of the examination. In certain cases the second year may, with the consent of the Council, be taken elsewhere than at Wisley, but each request for this special treatment will be considered on its merits. In 1926 the examination will take place from 6 p.m. to 9 p.m., on Wednesday, April 21. It will be held in as many different places in the British Isles as circumstances may demand, provided that a magistrate, clergyman, schoolmaster, or other responsible person accustomed to examinations has signified, by signing the candidate's entry form, his willingness to act as supervisor. Any candidate who wishes to do so may take the examination at the Society's Offices, Vincent Square, S.W.1., where arrangements for supervision will be made by the Society. Candidates must enter their names on or before March 31, 1926, with the Secretary, Royal Horticultural Society, Vincent Square, London, S.W.1., from whom entry forms may be obtained. An entry fee of 5/- must be sent with the completed form.

Mr. C. A. Bayford.—Like many another successful gardener, Mr. C. A. Bayford gained his early knowledge of gardening from his father, who was then gardener at High Elms (now renamed Garnton Manor), Hertfordshire. He remained with his father for three years and then passed on to the gardens at Moat Mount, Hendon; a year later he entered the famous gardens at Moor Park, Rickmansworth, where he was employed for two years. At that period every ambitious young gardener felt that a period spent at Chelsea was a necessary part of his career, so Mr. Bayford obtained employment with Messrs. James Veitch and Sons, and spent short periods in most of the departments of their extensive establishment, finishing in the decorative department. His skill in the arrangement of plants and flowers secured him the position of decorator at Floors Castle, Kelso, at a time when Mr. A. MacKeller was gardener there. From Floors, Mr. Bayford went to Madresfield Court as general foreman under Mr. W. Crump, and five years' experience under that very capable cultivator and organiser fitted him for the responsible position of gardener to C. Lee Campbell, Esq., at Glewston Court, Ross, where he had charge of the fruit plantations as well as the gardens and grounds. Mr. Bayford was a successful exhibitor, especially of hardy fruits, while at Glewston, but his stay there extended only to two years as the estate was sold. His next appointment was as gardener to the Earl of Lichfield, at Shugborough Hall, Stafford, whom he served for eight years before taking up his present position as gardener to C. W. Dyson Perrins, Esq., at Davenham, Great Malvern, Worcestershire. During the past score of years Mr. Bayford has carried out many alterations and improvements at Davenham, including the construction of a new Rose garden and rock garden, and the planting of a fine collection of early-flowering trees and shrubs. The beauty and upkeep of the gardens at Davenham are well-known in the Worcester district, and once a year C. W. Dyson Perrins, Esq., throws them open to the public on behalf of the Gardeners' Royal Benevolent Institution, for which, through the Worcester Auxillary, Mr. C. A. Bayford works continuously and successfully. This chartiy usually benefits to the extent of £30 a year from the opening to the public of Davenham Gardens.



MR. C. A. BAYFORD.

Resignation of Belgian Colonial Secretary.—The resignation is announced in the Belgian horticultural press of M. N. Arnold, Secretary-General of the Belgian Colonial Ministry. M. Arnold, who has just completed forty-two years of uninterrupted official duties, was mainly instrumental in the creation of the Botanic Garden of Eala, and the Colonial Garden at Laeken. He also sent out many botanical missions, consisting of the most eminent botanists, to the Belgian Congo, and it was under his auspices that the famous *Annals of Tervueren*, descriptive of the Congolese flora, was compiled by MM. Durand and De Wildeman.

Exports of Plants to Canada.—The Insect and Pests Advisory Board of the Canadian Department of Agriculture has had its attention drawn to the fact that the Canadian Customs Department, when checking permits against invoices of plants for clearance, often find that permits and invoices do not coincide, in that varieties appear on the invoice not included in the permit, or the numbers of plants on the invoice materially exceed those given on the permit. In such cases the Customs officers have no option but to refuse clearance. If an importer increases his order after the permit has been issued, he should return the permit for amendment. If the shipper increases the order without the knowledge of the importer, the latter may have his permit amended by telegraph, but in such cases will have to bear the telegraph charges. Shipments are not permitted to leave the port of importation unless a permit has been issued to cover their clearance, and containers should be marked with the correct permit number by the shipper, to assist checking and avoid delay. It has been reported that shippers have frequently used the same permit number for more than one shipment to the same individual, after the quantities authorised by that permit have been filled. This is contrary to the regulations. As from January 1, 1926, permits will be granted as valid for only one year from date of issue. In cases where a shipment is to be forwarded in two separate lots at different times, the importer is advised to secure a separate permit for each lot, in order to avoid confusion and delay. If, for any reason, only one permit has been secured, on arrival of the first portion of the shipment, the importer should present the permit to the customs authorities, who will check off the plants received and return the permit to the importer, indicating thereon the entry number under which the first portion of the shipment was released. Upon arrival of the balance of the shipment the importer will again present the permit when it will be taken up by the Customs Department to be filed with their entry papers.

Cyclamen at Hesketh Park, Southport.—Southport, the Garden City by the Sea, as it is often called, has long been famed for its magnificent display of flowers during summer and autumn. Good judges—men who have travelled—have stated that Southport has the finest public gardens in Europe; be this as it may, everyone who knows this beautiful seaside resort will admit that the floral display would be difficult to equal in its variety and extent. A remarkably comprehensive collection of Dahlias is grown, including about 20,000 of the brilliant Coltness Gem, the most striking and popular bedding plant of to-day. Herbaceous flowers in great variety, mostly planted in bold masses of one kind, Antirrhinums, Gladioli, Geraniums, and many other beautiful summer subjects, combine to make a display that impresses by its beauty residents and visitors alike. Not only during the summer, but also in the winter the cult of the beautiful is not neglected. For many weeks past, in one of the large glasshouses in Hesketh Park, Cyclamen have made a magnificent display (Fig. 70). Upwards of two thousand plants are grown, embracing pure white, white with rose base, scarlet, salmon, crimson, and some beautiful Petunia coloured flowers. The plants are in five-and-a-half-inch pots and six-inch pots, splendidly grown, with healthy foliage and an abundance of flowers. Seeds were sown in August, 1924, and the plants have been in bloom since last

October; at the present time, mid-February, the display is wonderful, and reflects great credit on Mr. Clark, the superintendent of parks. The seeds were supplied by Messrs. Clibrans, Ltd., of Altrincham. Whether for public or private gardens, there is probably no plant that so well repays cultivation as does the greenhouse Cyclamen for a display of flowers from October to March. Seedsmen have worked wonders with this family, new and beautiful colours have been introduced, the size of flower has been increased, and there is greater freedom of flowering and of vigour than formerly. Not only for a display but also for supplying cut blooms Cyclamens are of great value, and it is satisfactory to know that their cultivation is becoming better understood and, consequently, more widespread.

FIG. 70.—DISPLAY OF CYCLAMENS IN THE CONSERVATORY, HESKETH PARK, SOUTHPORT.

National Sweet Pea Society.—In the Schedule of Prizes offered for competition by the National Sweet Pea Society at its 1926 exhibition, no fewer than sixty-one classes have been provided. The exhibition is to be held in the Montpellier Gardens, Cheltenham, in conjunction with the Cheltenham Floral Fête, on June 30 and July 1. Nine of the classes are open only to growers residing within twenty-five miles of Cheltenham; the other classes are open only to members of the N.S.P.S. In addition to cash prizes, numerous cups, trophies and pieces of plate are offered, two of the finest being the Eastbourne Cup and City of Bath Cup, each open only to competition by the trade. The Society's artistic medal is also part of the prize in many of the classes. The Schedule extends to thirty-two pages, and in addition to the rules and regulations for the show, contains the rules of the Society, the Classification Lists, and the lists of Too-much-alike varieties. The schedule may be obtained from the Secretary, Mr. A. C. Bartlett, 19, Bedford Chambers, Covent Garden, W.C.2.

Appointments for the Ensuing Week.—Monday, March 1: Romsey and District Gardeners' Association's meeting. Tuesday, March 2: Royal Caledonian Horticultural Society's meeting; Wednesday, March 3: Abingdon Horticultural Society's meeting: Pangbourne Gardeners' Mutual Improvement Associations' meeting and lecture. Thursday, March 4: Western Commercial Horticultural Society's exhibition at Penzance (two days); Manchester and North of England Orchid Society's meeting; Friday, March 5: Dundee Horticultural Society's lecture; Accrington and District Gardeners' Society's meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Portugal Laurels at Trentham.*—The enquiry of a correspondent, signing himself "Pod," respecting some standard Portugal Laurels in the gardens at Trentham, has reminded us of promises made to other inquirers on the same subject; and, in order to convey a clearer idea of the appearance of these trees, we herewith give a sketch of one of them which is eight feet high, with a straight stem three-and-a-half feet in height, carrying a head eight feet in diameter. In the Italian flower garden at Trentham Hall there are sixty-eight such trees, than which nothing can be more appropriate or more admired; and the centre walk, which is forty feet wide and has seventeen standards arranged at regular distances on either side of it, is said to be the finest thing of the kind in the kingdom. The time and attention required to bring these trees to perfection accounts for our correspondent being unable to procure them ready formed from the nurseries. We are aware that some of the nurserymen are endeavouring to obtain them: but, when we state that at least six years are requisite in preparing them for placing in their permanent situations, it will be seen that there is much need for the exercise of patience. The trees at Trentham when first bought (about thirteen years ago) had their stems formed, but they had very small heads. They were then about ten years old; but we believe that, by selecting Portugal Laurels already large bushes, and by judicious management, standards may be obtained fit for placing in their tubs in five or six years. We would therefore advise those who wish to possess standard Portugal Laurels to form them for themselves; and to commence a search forthwith among plantations of trees from eight to ten feet high, selecting those with the cleanest and straightest stems, upon which the beauty of the standards considerably depends. Portugal Laurels which have been drawn up when young, from having been planted thickly together or among faster-growing trees, are very commonly found with clean stems three feet or even four feet in height; but, when allowed plenty of room, they seldom grow with straight stems, but generally begin to branch out close to the ground. *Gard. Chron., March 1, 1851.*

The Week's Work.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Phalaenopsis.—These useful winter-flowering Orchids have been blooming for some time past. The flower scapes should not be allowed to remain on the plants for a very long period or they will have a weakening effect on the latter. After they have been cut off the plants should be given a few weeks rest, affording them only sufficient moisture at the roots to maintain the leaves in a plump, healthy condition. The Spagnum-moss on the surface of the receptacle should be allowed to become quite dry between each application of water, which should be given by means of a small rose can. Owing to the succulent nature of their leaves and absence of pseudo-bulbs, these Orchids are amongst the most difficult to manage during the winter. They should be grown in a warm, buoyant atmosphere at all times, and not exposed to bright sunshine.

Vanda and Saccolabium.—Towards the end of the present month such warmth-loving Orchids as Vanda aërides and Saccolabium should be given attention. Many of these plants will be showing signs of fresh root action. The old, decayed Sphagnum-moss should be removed from between the roots and fresh moss substituted. Specimens that have lost many of their lower leaves and have new roots developing from the stem should be re-potted. Cut them back at the base to within a few inches of the living roots, then place the plant in the pot so that the foliage is near to the soil. It will probably be necessary to place the stem in the receptacle before the drainage material. Fill the pot or pan one half its depth with clean potsherds. Employ clean, picked Sphagnum moss as a rooting-medium, mixing portions of broken pots amongst it to assist the water to pass through freely. Fill the receptacles to their rims and arrange the materials higher in the middle than at the sides. Finish with a layer of heads of living Sphagnum-moss over the surface. Clear the plants from scale insects which infest the stems and axils of the leaves.

Angraecum.—Angraecum is a closely allied genera to those already mentioned. The strong-growing kinds, which include A. sesquipedale, A. eburneum and A. Eichlerianum may be grown in pots and treated similarly to Vandas. The smaller-growing species, of which the sweet little A. citratum is an example, succeed best in shallow Orchid pans.

FRUITS UNDER GLASS.

By T. PATEMAN, Gardener to SIR CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Cherries in Pots.—Those who wish to have ripe Cherries in May and early June must exercise a little patience when starting the trees into growth and be sparing with the use of fire-heat, which should only be afforded in the early stages of growth, when the external temperature is below 35°, to maintain a mean temperature of 42°. Full use should be made of solar heat which is most favourable for steady forcing. Cherries are impatient of fire-heat, and many failures may be traced to this error in cultivation, for a hot, dry atmosphere is inimical to success. So soon as it is noticed that the buds are swelling, the mean temperature should range from 45° to 50°, with a rise of 10° during the day, but it should be understood that the mean temperature is only given as a guide. On mild nights it may exceed 50° by several degrees without causing harm. As the days lengthen more air may be admitted through the top ventilators, and ventilation is essential when artificial heat is needed. A careful watch should be kept for insect pests, such as green and black Aphides, during the time the trees are in bloom. It will be wise to spray the trees with a nicotine wash, for no matter how carefully the trees were cleansed when they were dormant, aphides are sure to become a source of trouble unless these precautions are taken. When the trees are in bloom it will be wise to shade the flowers from bright sunshine; these precautions taken, a good set of fruits should be ensured.

Cherries in Borders.—Trees planted in borders and growing in a cold house should be retarded in growth for so long as possible, by keeping the ventilators open night and day until such time that it is found necessary to close them at night to protect the flowers from frost. In the meantime see that the borders are supplied with sufficient moisture; but at this season of the year do not water the border so liberally as to cause stagnation. Spray the trees with nicotine wash when it is found that the buds are nearing the opening stage, as recommended for pot Cherries.

Winter Tomatos.—Although the winter has been cold and sunless Tomatos have done exceptionally well here. Our plants are grown in ten-inch pots in a temperature not exceeding 60°. They have been lightly fed with liquid manure and frequent dressings of sweet rich soil have been applied to assist the plants to swell their fruits. To provide a succession, young plants raised from seeds sown last month should be kept growing in a moderate heat, and potted on until they are finally potted in ten-inch receptacles which should only be partially filled with soil to allow room for several top-dressings of rich soil, when two or three trusses of flowers have set.

PLANTS UNDER GLASS.

By JOHN COUTTS, Assistant Curator, Royal Botanic Gardens, Kew.

Lathyrus pubescens.—This plant has lavender-blue, sweet-scented flowers, and is an excellent subject for the cool greenhouse. It succeeds best planted out on a raised bed and the shoots trained to wires under the roof-glass. In its season it is an excellent plant for furnishing a supply of cut flowers. It is hardy in the south and west, trained up a warm wall. Plants may be raised from seeds sown at this time in a warm greenhouse, but flowers are not produced until the second year from seed-sowing. A few plants should be raised each year for succession, as this Lathyrus is not long-lived, and the best results are obtained from young, vigorous stock.

Gloriosa.—The tuberous roots of Gloriosas, which have been stored in dry conditions all the winter, should now be placed in suitable-sized pots, the size of which will vary according to the size of the tubers; as a general rule, ten-inch pots are necessary for large roots. Offsets that may have formed should be carefully removed, taking care not to injure the brittle roots. The stock may also be increased by means of seeds. G. superba is a very old garden plant and the best known species. It succeeds best in a moist atmosphere of 60° to 70°. Use a rich, well-drained compost consisting of loam, fibrous peat and sand. During the growing season the plants should be given suitable support, as they climb by means of tendrils at the ends of the leaves. As the growth ripens, reduce the amount of water at the roots, as it is very important that the tubers should be stored dry, and kept in a warm situation during the winter. Other species are G. simplex (syn. virescens) and its variety Plantii, with reddish yellow flowers; G. Carsonii and G. Rothschildiana, with beautiful crimson flowers. This last is generally afforded stove treatment, and it is not generally known that it succeeds perfectly in an ordinary greenhouse. It is, however, an advantage to start the plant in a warm house and gradually accustom it to cooler conditions.

Alocasia.—As a rule, the many beautiful species of Alocasia require to be re-potted every year, and February or the beginning of March is a suitable time to undertake this work. The compost should consist of good fibrous peat mixed with a little fibrous loam, a liberal quantity of Sphagnum moss, lumps of charcoal and plenty of silver sand; some old soft bricks, broken finely, may, with advantage, take the place of a portion of the sand. The pots or pans should be about two-thirds filled with clean crocks. The plants and compost should be well raised above the rim of the pots, finishing off the surface with Sphagnum-moss, or the short green moss known as bun-moss. Alocasias enjoy a high temperature of 70° to 75° with plenty of atmospheric moisture, and when well-rooted and growing freely should be afforded ample supplies of water at the roots. Shade them from bright sunshine during the spring and summer.

Anthurium.—These foliage plants succeed under the same treatment as Alocasias, but usually it is better to re pot them earlier than Alocasias, and as they are not dried off much greater care is required to preserve the live roots. If they are in good condition it may not be necessary to re-pot them every year, a top-dressing of fresh compost sufficing. When re-potting them, all dead and decaying roots should be trimmed off, while if it is desired to increase the stock, it is best done at this time by division.

THE KITCHEN GARDEN.

By F. STREETER, late Gardener to MAJOR ALBERT PAM, Wormley Bury, Broxbourne.

Exhibition Onions.—Seedling Onions are ready for pricking out into other boxes. Crock a sufficient quantity of sound boxes and fill them with the following compost: three parts good fibrous loam, one-part leaf-mould, one part old Mushroom-bed manure, one six-inch potful of bone-meal per bushel of soil, a dash of soot and sufficient sand to render the mixture porous. Make the soil thoroughly firm in the boxes and prick out the finest and strongest plants. Water them well and place the boxes in a warm house near the roof-glass in a position free from cold draughts.

Autumn-sown Onions.—So soon as the bed can be got into a proper condition for planting, autumn-sown Onions should be planted out. Give the bed a liberal dressing of dry wood-ash and soot, and draw sufficient very shallow drills just for the purpose of marking the rows. Allow a space of twelve inches between the plants in the rows which should be fifteen inches asunder. Select the best seedlings with good roots and plant them very firmly, raking the soil after each row is finished.

Plants in Frames.—Give all vegetables intended for planting out of doors later full air on all possible occasions. Peas, Beans, Cauliflowers and Lettuces growing in boxes should have the lights removed altogether during the daytime if the temperature is above 35°. This hardening is most important, and will greatly help the plants to overcome a check when they are placed in their growing quarters next month.

Seakale.—The thongs having been prepared during wet weather and heeled in outside, should now be placed in boxes of fine soil or sand and stood in a cold house to start sprouting. This will give them several weeks' start over the roots left and planted outside.

Forcing.—Continue to watch the crops of Rhubarb, Seakale, French Beans, Lettuces and Radishes to keep the supply well up to the demand of the establishment. Sow French Beans fortnightly in plenty of moisture and heat, for so soon as one batch is cropping another should be in readiness to take its place. Use the Beans in a young stage. Prepare work in advance as much as possible for the coming month, which is one of the busiest of the year.

THE FLOWER GARDEN.

By F. C. Puddle, Gardener to Lord Aberconway, Bodnant Taly-Cafn, North Wales.

Anchusas and Verbascums.—To maintain vigorous stocks of the several varieties of Anchusa italica and the hybrid Verbascums Caledonia, Ivanhoe, New Departure, etc., it is advisable to propagate a number of plants each year by means of root-cuttings. A few old plants may be lifted and the roots cut into four-inch portions, in the same way that Seakale cuttings are prepared. The root-cuttings should be placed in boxes containing sandy soil until they callus and signs of top-growth are apparent. They may then be planted in nursery beds for the first season.

Montbretias.—The large-flowered varieties of Montbretias such as His Majesty, Pocahontas, Joan of Arc and Queen Alexandra, which have been grown in frames for the winter, have produced a number of stolons, and these form a ready means of increasing the stock. The stolons are sending out roots and are sufficiently large to be separated from the parent corms. If these are taken off and planted three inches apart in frames they will make strong specimens that will flower in late summer, equally as well as the parent corms. The Earlham Hall varieties are not quite so hardy as the older hybrids, and they should not be planted in the open before the middle of April as the young growths are liable to be injured by spring frosts. A well-drained, sunny border should be chosen for their flowering quarters, and they will amply repay the little extra trouble necessary for their successful cultivation. The older varieties, crocosmaeflora, Lord Nelson, Lady Hamilton, etc., should be lifted and divided every alternate year, and the present is a suitable time to carry out this work. Lift the clumps and separate the corms, reducing the number of stolons to three. The corms should then be replanted from four inches to six inches apart in groups. Montbretias are very effective in herbaceous borders, and they are equally useful for brightening the shrubberies in late summer, but perhaps the most charming combination is obtained by planting them in Azalea beds in conjunction with Lilium tigrinum, as the flowers blend beautifully with the autumnal foliage of the Azaleas. If rabbits are troublesome Montbretias should not be planted too sparsely, as these pests will eat off single growths and leave the thicker clumps untouched.

Phacelia campanularia.—This pretty blue-flowered annual (Fig. 71) gives a succession of bloom over a long period; its bell-shaped flowers are a brilliant ultramarine-blue. Seeds should be sown during the next few weeks. This Phacelia makes a good edging plant.

HARDY FRUIT GARDEN.

By W. Auton, Gardener to Viscount Elveden, Pyrford Court, Woking, Surrey.

Planting.—Where large planting schemes are intended or have been in operation during the present season, those responsible for carrying out the work have been more than usually handicapped and much late planting has necessarily been done. Trees and bushes which may have been heeled in awaiting better conditions should be planted in their permanent positions forthwith. Late-planted trees are liable to suffer from dryness during the spring hence they should be watched and watered if necessary, but the greatest safeguard is to well-mulch the roots with partially-decayed manure immediately after planting.

Pruning.—Weather conditions not being quite such a governing factor in pruning as in planting, the bulk of the pruning generally will now be finished, but any still in arrears should be completed so soon as possible. Where the pruning of Gooseberries and Currants has been deferred because of possible losses from birds picking out the buds, the work should now be commenced. Where birds are very troublesome it is sometimes necessary to protect the bushes by netting them entirely, but to make this really effective a skeleton structure should be erected over the whole plot so that the netting may be kept in position well above the bushes. This is not always practicable, and the next best thing is to spray the bushes with something distasteful. For this purpose, I know nothing better than a solution of soft soap with a little Quassia extract mixed with it. Its efficacy does not last any great length of time in showery weather, hence periodical sprayings during the next few weeks might be necessary, but it has the advantage of being perfectly safe to use, whereas sprays of a sticky or tarry nature may prove injurious to the expanding buds.

General Remarks.—The swelling of buds, generally, is proceeding, and if any spraying remains to be done no favourable opportunity should be lost to complete the work, as it is somewhat risky to apply caustic sprays after this date. All well-established borders or quarters of fruit trees which have not been top-dressed this season may receive a mulching of good farm-yard manure, if this is obtainable, otherwise a dressing of good rich loam, with a liberal addition of bone-meal may be applied. This application of rich material is beneficial to all kinds of fruiting bushes and trees at this season, as it affords plant foods which will be assimilated by the roots, thereby imparting vigour to the latter and helping to increase the weight and quality of the fruit. The urine of animals diluted with about five times its volume of water forms an excellent manure for bush fruits and when these quarters are on the old side, it may be applied with particular advantage from now onwards as growth advances. Where Medlars and Quinces are grown see that any necessary thinning of the branches is done so that light and air will reach every part of the tree.

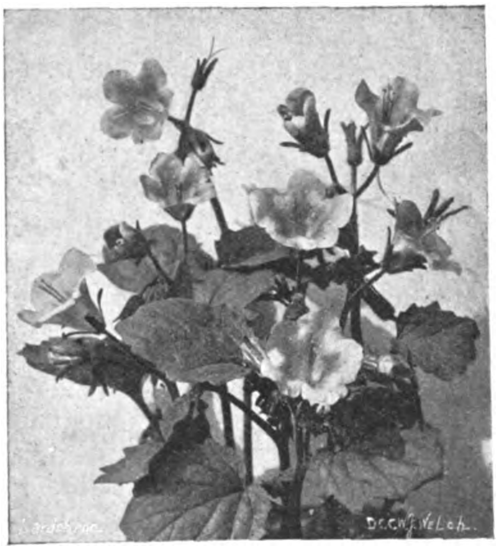

FIG. 71.—PHACELIA CAMPANULARIA.

Wall Trees.—Trees which were planted earlier in the season and were left untied until the natural sinking of the soil had completed should now be pruned and tied in position. In the case of transplanted fruiting trees, these will probably have been summer-pruned, and little pruning will now be necessary beyond removing shoots for which there is insufficient room. Young trees which have not enough growths to form the foundation of the future fruiting tree should be cut back to the points considered necessary to ensure the foundation. Early-flowering Peaches and Nectarines will soon be opening their flowers, and preparation should be made for protecting the trees until fruit has set. Where provision is made for the raising and lowering of thin tiffany blinds this is highly satisfactory, but where no such facilities exist double fish-netting hung at distance of a foot or eighteen inches from the wall has considerable protective power.

FOR NORTHERN GARDENERS.

By A. T. Harrison, Gardener to the Marquis of Ailsa, Culzean Castle, Maybole, Ayrshire.

Protecting Fruit Blossom.—With the first days of March, fruit trees on south walls usually begin to develop rapidly, and some means of protecting the blossoms are necessary. Where movable glass copings are employed, these should be placed in position; if these are not available protection may be afforded by a double thickness of fish netting arranged on poles leaning against the wall, just under the stone coping. This method allows room to walk between the nets and the trees for pollinating the blossoms by means of a rabbit's tail fastened to a cane. It is remarkable how nets used in this manner not only ward off several degrees of frost, but temper or minimise the effects of cold, boisterous March winds.

Peach Houses.—Peaches and Nectarines in cold houses are expanding their flowers, and during cold spells the front ventilators should remain closed to prevent cold draughts passing through the houses. On mild days the ventilators should be opened to their fullest extent to allow bees and other insects to enter. If the weather is not propitious for this, the rabbit's tail already referred to should be employed when the pollen is dry, passing it carefully from flower to flower, and giving each branch a sharp tap to aid in disseminating the pollen. This operation should be performed frequently while the trees are in flower in order to secure a regular set of fruits all over the trees, from which a selection may be made later suitable for a crop.

Early-flowering Chrysanthemums.—If cuttings of early-flowering Chrysanthemums have not been inserted, the present is a good time to put them in, using the young growths which are developing at the bases of the stock plants, which have been wintered in frames or cold houses. Cuttings inserted in sandy soil, either in boxes or in frames, soon make useful plants, and are ready for setting out in May, as a rule, without further stopping, and they will flower in advance of much earlier-rooted plants. Some of the varieties will be in flower by the end of July, and a great number from the middle to the end of August.

Regal Pelargoniums.—Plants which were re-potted during October and have been wintered in cool conditions are breaking into growth, and where these growths are likely to become crowded they should be disbudded freely. If more stock is required these young growths may be taken off when about three inches long and inserted in sandy soil. They will soon form roots, and if potted on as required. form useful specimens for blooming next winter,

Autumn-sown Onions.—These have wintered well where sown, but they should now be lifted and transplanted on well-prepared borders. Do not use a dibber for this operation, but stretch a line, and take out a shallow trench with a spade, placing the young Onion plants about six inches apart and filling in part of the soil around the roots by hand, finishing with the spade or rake before proceeding to the next row. Make the soil quite firm by treading. Autumn-sown Onions are very valuable in districts where the Onion-fly makes spring sowings very precarious and although exhibition bulbs may not be produced in this way, useful bulbs for the kitchen use are obtained, and at a time when the larger bulbs are still swelling.

Spinach.—Where Spinach is in demand a sowing should be made now to succeed the autumn-sown crop. This vegetable has wintered very well, and will come in extremely useful when green vegetables are scarce, and is much to be preferred to the perpetual or Spinach Beet usually sown for early use, although the value of the latter should not be overlooked when difficulty is experienced in wintering the prickly-seeded kind. The large quantity of edible leaves produced by Spinach Beet makes this vegetable one of the most profitable of edible foliage plants to cultivate.

FLORISTS' FLOWERS.

CHRYSANTHEMUMS FOR HOUSE DECORATION.

By cultivating early and late-flowering varieties, Chrysanthemums may be had in bloom for over five months of the year. The members of the Masse family commence to flower at the end of August and give a good supply of cut blooms for quite a month. These varieties may be planted out in the open border not later than the first week in May. Previous to planting, the border should be well dug and the soil enriched with a liberal amount of well-rotted manure.

Set the plants about two feet apart and support them to small Bamboo canes to prevent the shoots being broken off by high winds. By June the plants will be growing freely and need the additional support of strong stakes, two feet high, placed one on each side. So soon as the flower buds begin to show, remove all the weak growths, and rub out the centre bud of each spray; this will result in the side buds being stronger and insure a more evenly balanced spray.

So soon as the flowers commence to show colour, cut around each plant with a spade, about six inches from the stem, and in about ten days they will be ready for lifting and transferring to a cool house or pit. The roots require to be well-watered at the time of lifting; a thin shading may be used to prevent the plants from flagging and will protect the flowers from hot sunshine.

Cranford Yellow treated in this way will give an abundance of flowers; Almirante, is best grown in pots, and needs to be disbudded freely to obtain good flowers.

When the flowering season of these Chrysanthemums is over, a few old stools of each variety should be planted out in a cool frame or in boxes and put into a cool frame for the winter. They will need protection from sharp frosts. In the spring they will produce plenty of young growths, with roots attached, suitable for planting out or for potting.

Some of the members of the Caprice family still find a place with me; Kathleen Thompson and Caprice du Printemps in particular are valuable to carry on the succession of flowering at the end of October. In May these sorts need pinching if they do not break naturally. The yellow single, Phyllis Cooper, if pinched back in April, comes into flower in good time. The yellow incurved Advance is rather weak in the stem, but it is very free-flowering and suitable for producing large single blooms. The white, incurved H. W. Thorp may also be grown for sprays or single blooms. Hortus Toulousanus, old gold and bronze, is a variety of pleasing colours; Margaret de Quiney, delicate pink, is of very compact habit and makes a good bushy plant; Mrs. W. R. Smith has fine, massive white flowers; Louise Louppe is another good white sort; the growth is compact and it makes a fine decorative plant.

Mollie Godfrey, deep pink, grows six feet to seven feet tall, and produces very fine flowers. Sandown Radiance is undoubtedly the finest colour of its class and Miss A. Brooker, chestnut-crimson, is a good companion to it. William Turner, white, is a most useful Chrysanthemum for early December blooming; Audrey, orange-yellow, is a very handsome and showy variety. Tuxedo, orange, is a rather tall grower, but late in flowering, being useful in December. Madame R. Oberthur has long, pure white florets and makes a very pretty bloom but is rather weak in the stem. Christmas White and Baldock's Crimson are both useful at Christmas.

The deep yellow variety Nagoya is also at its best at Christmas and is one of the choicest of these Chrysanthemums. The latter, with Enfield White and Winter Cheer, will give an abundance of flowers all through January. Edith Cavell, light bronze, although a large-flowered variety, makes a splendid bush for decorative purposes if grown on and disbudded.

By growing sufficient numbers of all the varieties I have mentioned, an abundance of flowers will be assured from the end of August until well into February of the following year.

The varieties that are grown in pots should be rooted in boxes of a standard size, on the shelves of a greenhouse where the temperature does not fall below 40° at night. They should be grown in a compost of two-thirds loam and one-third decayed leaf-mould, lightened with sand.

Very little damping off will occur when the cuttings are rooted in this way. When nicely rooted they should be potted singly in sixty-sized pots, using similar compost as before with the addition of a little mortar rubble and horse droppings passed through a fairly fine sieve. When potted, place them back in the same temperature for a week or so, then remove them to an almost cool house. Early in March they will require another shift into forty-eight-sized pots, and for this potting the compost needs to be a little coarse; if the loam is of a heavy nature, wood ash and a liberal amount of mortar rubble should be added to it, also the siftings from broken pots and a little charcoal to keep the soil sweet.

The next potting should take place about the third week in April; transfer the plants to twenty-four-sized pots, using a compost of a lumpy nature and rather heavier in texture than before, with plenty of opening material mixed in it; also to every barrow-load of soil add a thirty-two potful of bone-meal.

After potting, the plants should be neatly tied to a small Bamboo stick and placed in a cool pit or frame, where they can be protected from heavy rains and rough winds; during favourable weather the lights should be taken off entirely. By the beginning of June the plants should be shifted into their flowering pots, number twelves being suitable.

The loam for the last two pottings is best pulled to pieces by hand, and for the final shift add a little more bone-meal than advised for the previous potting and a liberal amount of horse droppings in a coarse state. After potting, place the plants in their summer quarters and attend to staking and tying, as required. By giving the plants four shifts I find they are able to withstand the heavy rains during the summer, which often occur after their final potting. *E. Neal, The Gardens, Tilgate, Crawley.*

PERPETUAL-FLOWERING CARNATIONS.

I quite agree with Mr. Grigor Roy (see p. 122) regarding Mr. H. Howard Grace's article on Insect Pests. I had under my charge at the Preston Hall Training Colony, Aylesford, Kent, some 50,000 perpetual-flowering Carnations in all stages of growth, 25,000 on the bench system, the remainder in reserve and for pot culture. I was in no way troubled with red spider as I kept the hose going during spring, summer and early autumn in houses with the bench system, while other plants were syringed, using force, with reasonable care.

The temperature maintained during winter, and on dull, sunless occasions was 55° by day, and 50° by night, and we used artificial heat to ensure a buoyant atmosphere. Air was admitted on all favourable occasions, always avoiding cold draughts. I prefer the temperature to rise with sun heat rather than admit cold winds. At the same time, there must be a check on artificial heat, because therein lies the encouragement of red spider and all other insect pests.

During the six years I was at Preston Hall, not a bloom required wiring; some of my friends who may see this will quite bear me out on that point, while the many prizes we won, including the Clifford Cory Challenge Cup in 1922, will show that spraying is necessary to ensure success. *J. Childs, The Gardens, Chalet du Bois, Le Touquet, France.*

BULB GARDEN.

GALANTHUS CILICICUS.

I was much interested in Mr. Besant's note on this species in *The Gardeners' Chronicle* of February 6 (p. 98). He states that at Glasnevin it is rarely (if ever) in flower before the New Year. I planted a few bulbs in October, 1923, in a warm corner of the rock garden, sheltered from the east by a large rock. These produced a few flowers the following December, but in December, 1924, they all flowered well, and better still in November, 1925. I have no record of the date on which the first flower opened, but it was quite early in November, and the clump continued to bloom until well into December—altogether a most satisfactory performance. This is a mild district, which may have some influence on the period of flowering, but it seems to me more probable that there are different races of the Cilician Snowdrop in cultivation, some of which naturally flower much earlier than others. At any rate, it is a valuable addition to gardens where Snowdrops are appreciated as it is sure to flower some weeks before the ordinary G. nivalis, or G. Elwesii, have even appeared above ground.

Mr. Besant mentions Iris unguicularis Imperatrice Elizabetha as flowering well at Glasnevin this winter. It is the only one of seven or eight named varieties of I. unguicularis which refuses to flower at all in my garden; its neat habit and narrow, grassy foliage suggest close relationship with I. u. cretensis, which is flowering freely alongside it. My plants came from Glasnevin in April, 1922, but, so far, I have never seen a flower on them. All the broad-leaved forms are flowering with extraordinary freedom this season, the first bloom having opened on October 11. *N. G. Hadden, West Porlock, Somerset.*

TREES AND SHRUBS.

CISTUS VAGINATUS.

This is the only species among a fairly representative collection of Cistuses which must be regarded as too unreliable for out-door culture here. We have grown this Cistus for many years, but it has always suffered more or less from frost, and this winter over 20° for several nights very nearly killed our soiltary plant.

It is probably the tenderness of C. vaginatus which accounts for the shrub's rarity in gardens generally, but it should be a valuable addition to those gardens nearer the western sea than we are, and especially to those in the south-westerly counties. Our specimen has attained a height of about four feet, but the species grows much taller. The leaves are narrow, pointed at each end, and up to six inches in length. These, as well as the young wood, are very hairy and sticky.

The pale purple flowers are larger than those of any other Cistus I have seen (excepting, perhaps, those of C. ladaniferus var. immaculatus), being some five inches in diameter and opening quite flat. This species has never set seeds here, and compared with others of the genus, it is a difficult shrub to propagate from cuttings. *J., N. Wales.*

POLYGONUM BALDSCHUANICUM AND P. AUBERTII.

It is dangerous to write from memory and still more to venture to offer an opinion contrary to that set forth by so good a plantsman as the writer of the note on these Polygonums on page 137. But I do not think Mr. P. Ruy does full justice to P. baldschuanicum, nor may his opinion that P. Aubertii is a preferable plant be accepted by all. Where there is plenty of moisture in the ground and ample space to be filled, there is, I think, no finer plant than P. baldschuanicum, particularly if its flowers are a mass of pure white. It climbs and ramps and flings its flowering branches wide, and blooms from August until the end of September.

Where, however, the soil is too dry for it, P. baldschuanicum is nothing at all.

Yet other merit this sturdy climber has. It propagates itself, and a well-established plant is always a fertile source of supply of well-rooted side shoots. P. baldschuanicum, moreover, is so tolerant of pruning that when it has outgrown the limits assigned to it, cutting down to the ground does not in any way dishearten it—except of course that there are fewer flowers in the first year after cutting it back. P. Aubertii has a more graceful, daintier habit with smaller racemes of white flowers. Trailing over the posts of a rustic bridge on the other side of which is the multijuga variety of Wistaria sinensis, it holds its own in beauty with that lovely plant. Therefore, if I am right in discriminating between the two species, the conclusion must be reached that each is a splendid garden plant, and both should be grown by everyone who can provide them with the moist conditions which, in my experience, are essential for the successful development of these plants.

It may be added that the white form of P. baldschuanicum fades slightly to pink, and that the pink form is generally of too indecisive a tint to be quite pleasing. *A. N.*

WOODLAND GARDEN.

ANEMONE NEMOROSA.

Our common Wood Anemone is one of the most delightful of all spring flowers, and here, in the west, it has an extraordinarily long season, and gives us an infinite range of varieties in the colour of the flowers. Commencing with a rather small, pure white form, which often appears as early as the Lesser Celandine, its flowering continues well into May, the latest to bloom of those indigenous to our own woodland being a large-flowered variety, the blossoms of which are a bright mauve on the reverse and lilac within. Between these two extremes there are numbers of forms showing graduations of colour and size.

The well-known varieties Allenii, Robinsoniana, Blue Bonnet and others of the class colonise freely, as might be expected, since the wildlings find our light loam and westerly slope congenial. But the so-called Welsh Anemone (A. n. var. coerulea) I have not found growing in woods in this or any other part of the Principality. It occurs in vast numbers on many a breezy, treeless, upland sheep-walk, especially it would seem in the slate producing districts. Last year I came across some fields and a railway cutting which were liberally blued by these pretty flowers, but on closer examination I noted that here again there was a very wide variation in the colour—whites, thin pinky-lilacs and both pale and lavender-blues, all growing together in the grass The flowers were rather small (possibly because the altitude was considerable), and they were held perfectly upright on the stalk.

These blue Anemones flower a good deal later than the rest in my experience, which may account for the lateness of Blue Bonnet, which is said to be derived from the Welsh Anemone. Then there is A. n. var. cornubiense (Robinsoniana cornubiense) also one of the later ones, but this form—if I have the right plant—is of poor colour, not so good as many of the wild mauvy-purple ones.

A. trifolia, which some consider to be an alpine form of A. nemorosa, is in every respect an admirable little plant. Rather heavier in leaf and stiffer than our own species, A. trifolia is a robust coloniser, soon making very dense mats of roots and covering many yards of ground. The milk-white flowers, which nod above the pale green leafage, are exceedingly pretty, and they are borne from March to May. I have seen this little plant flourishing in the densest shade of a Douglas Fir, and have yet to find conditions under which it will not do well. Farrer refers to a lovely blue variety of A. trifolia which he saw in the woods near Misurina, but this I have never seen nor have I been able to obtain it. *A. T. Johnson.*

MR. F. KINGDON WARD'S EIGHTH EXPEDITION IN ASIA.*

XXVI.—Through Bhutan to Railhead.

Both Cawdor and I had superficial frostbites on our noses as a result of the last few days of our crossing the Himalaya, and were glad to get down into warmer regions. However, the weather in the valley of the Nyamjang river (Fig. 72) was distinctly bad for the next few days, and a lot of snow fell on the mountains, making it cold and damp.

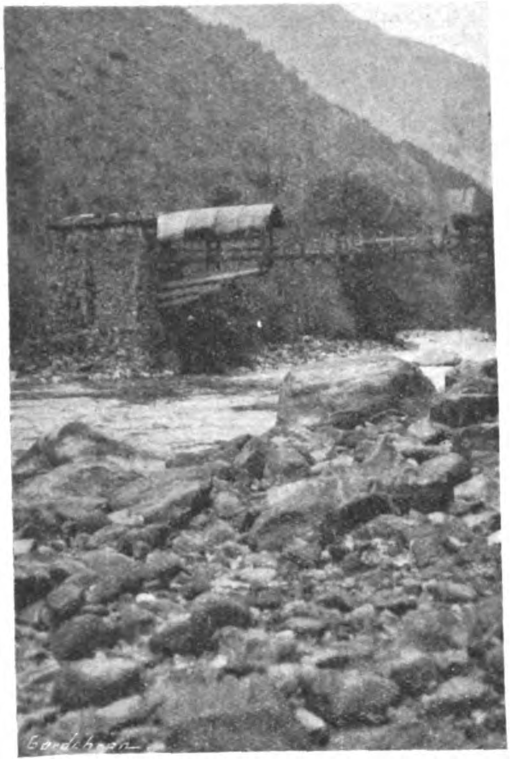

FIG. 72.-CAPT. F. KINGDON WARD'S EXPEDITION; BRIDGE OVER THE NYAMJANG RIVER, BHUTAN.

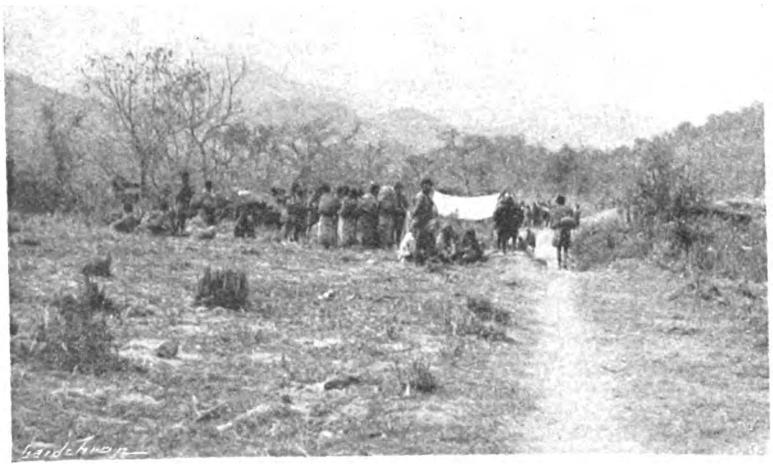

FIG. 73.-CAPT. F. KINGDON WARD'S EXPEDITION: THE PLAINS OF ASSAM, OVER THE FOOT-HILLS OF BHUTAN.

All our pack transport returned to Tsöna, and from this village to India we had to depend on cooly transport. So we started off on February 10 with forty-five coolies (Fig. 73), and did a full day's march through lovely forests, descending some 2,000 feet, which took us right out of the snow; and on the following day, too, we descended such a long way, sometimes down flights of steps, that we quite expected to reach the plains within a week.

At first the forest was Conifer, with many Rhododendrons, including a 'Lepidotum,' the 'Arboreum' already referred to, and R. Maddeni. The 'Arboreum' was here a small tree and a little lower down we met with it in flower.

From Tsuga and Juniper, we descended into forests of Pine, with a great variety of bushes by the stream—Rosa, Piptanthus, Salix, Clematis (in flower), and so on, very much as in the Tsangpo gorge. Still lower down, during the third day's march, we met with many things in flower—a white Daphne, Berberis sp. and a whole sheet of purple Primula atrodentata under a waterfall. By midday on February 12 we were amongst semi-tropical vegetation. There were Ficus trees; there were Orchids in bloom on the branches: there were Aroids, and flowers such as species of Strobilanthes, and Crawfordia. And then abruptly the whole scene changed. The broad, rocky valley contracted to a dun-coloured glen with no way through, and we had to climb 1,500 feet up the cliff by a very stiff path, and then wind round the gullies, from spur to spur.

We were now in a much drier climate, in fact in a more typically dry-winter region, most of the storms passing over this part of the valley. Consequently the slopes were clothed with Pine and Bracken, with Oak, and with Rhododendron arboreum, now in full bloom. Prominent on the rocky, grass clad slopes were masses of the brilliant gamboge Lindenbergia grandiflora, one of the Scrophulariaceae, with flowers rather like a Bartsia. We passed through several villages, the houses being of stone, sometimes roofed with Bamboo; cultivated terraces were already green with spring Wheat.

On February 13 we had to descend to the river again, cross by a hammock bridge, and climb high up the other side, where we found Oranges growing. Next day, continuing high up on the right bank, over sharp schistose rocks which were rapidly cutting my last pair of boots to ribbons, we passed the junction of the Tawang river with the Nyamjang—the route we had intended to follow from Tsöna, and immediately afterwards crossed the frontier into Bhutan. We expected to be held up here, but finding the first Bhutanese village deserted, we persuaded our carriers to go so far as the next one; and though it was quite early in the afternoon, here we had to stop and explain our presence. However, the local Bhutanese authorities, far from being unkind, were very helpful, and promised us transport for the following day, when we should reach Trashigang Dzong, where the local chieftain resided.

---

* The previous articles by Mr. Kingdon Ward were published in our issues of April 12, May 17, June 21, August 9, August 30, September 27, November 1, 1924; April 4, May 9, June 6, June 20, July 4, July 18, August 1, August 15, September 5, September 19, October 10, October 24, November 21, December 5, December 19, 1925; January 2, January 16, and February 13, 1926.

From this village we could see the spurs running down to the plains, and had it not been for the dust haze, which at this season always hangs over northern India, we might have seen the plains themselves ; we were told they were only six marches distant. Up here there was still a good deal of leafless Oak forest, with scarlet Rhododendron and Pine trees scattered down the slope. On the 15th we descended once more to the Nyamjang, now a big river, and continued by it for some miles to Trashigang bridge. Owing to difficulties with the transport, our coolies did not reach the bridge-house till nearly midnight, and then we had to leave half of them behind to join us next day.

A fine iron-chain bridge spans the river here at a height of a hundred feet above the water ; and 1,200 feet up the opposite bank the *dzong* sat astride of a narrow ridge. However, the kind old chief sent ponies down to the bridge to bring us up, and we arrived in state next morning. All he asked was that we should spend the day with him, which we did ; we also gave him our folding camp table.

There were many Leguminous trees down in the river valley—or gorge, rather, as it was in this comparatively arid region. I noticed species of Cassia, Indigofera, Desmodium, Acacia, Bauhinia, and Butea, some of them in flower. But it was only fringing the river that one got this strip of forest vegetation, with clumps of Euphorbia, and a few rather striking flowers such as Sedum and several Orchids. Higher up, the precipitous, rocky cliffs were almost bare except for scattered Pine trees ; and we had to ascend 2,000 feet to 3,000 feet from the river in order to find solid forest again, except in the deep gullies. A small Ceratostigma with brilliant cobalt blue flowers was seen near the *dzong*.

The pace had now slowed down considerably, but on February 17 we got off again, the Dzongpön lending us ponies for the first day's stage ; we were told we should reach India in five marches ; but as we discovered, they would need to be long ones, and one cannot make long marches through almost uninhabited country with a column of forty-five porters.

After leaving Trashigang we began to climb again. The road to India now leaves the river slanting away to the south-east and crossing a number of its tributaries, separated from one another by Pine-clad spurs ; the country, in fact, recalled many parts of western Yunnan. Each day we crossed a spur, from one valley to the next, so that sometimes we were in sub-tropical jungle, amongst Tree Ferns and Palms, and sometimes in the open Pine forest, where the scarlet Rhododendrons were in full blaze. They flower much earlier here than they do in Sikkim, a little further west.

The first two days was a continuous climb, as we had to get out of the main valley ; and on the second day we crossed a pass at a height of about 9,000 feet, the highest we had been for some time. But after descending to the first stream, we never again climbed above 5,000 feet.

At this altitude in eastern Bhutan we found the exposed slopes sometimes clothed with long grass and Bracken, with scattered clumps of Gaultheria, Vaccinium, and other underbush shrubs, and sometimes wooded ; the trees were Rhododendron arboreum (small compact and gnarled trees, hoary with age), Oak, Alder, (A. nepalensis), Schima, etc. The sheltered slopes, however, were clad with thick forest containing a large proportion of Bamboo, and such large-leafed Rhododendrons as R. grande. Pieris formosa was in flower in the Pine forest.

The road was surprisingly good for such a sparsely-inhabited, hilly country, and we met numerous gangs of coolies, who had been down to the plains, returning with goods for the market at Tawang or elsewhere. Mules, ponies and even sheep are used for pack transport.

The forests of scarlet Rhododendron were now a gorgeous sight, and it was surprising to find this species blooming so freely at 5,000 to 6,000 feet in the Pine forest, and then see the same thing 4,000 feet lower down, flowering amongst the Screw Pines, Engelhardtias, Clerodendrons, arborescent Compositae (Vernonia), and Strobilanthes of the jungle. I thought these last had rather more carmine flowers, while at higher elevations the flowers were blood red, or crimson; but the flowers certainly change shade as they age.

In the Pine forest, on steep, rocky slopes, I noticed scattered plants of a Lily, which looked as though it might be quite a fine thing. It is a plant of about two feet, bearing a single terminal flower, which, judging by the size of the rather oblong capsule, must be big. The bulb is small, and grows about six inches down, in a very light, friable soil which, though fine, is full of angular stones. During the winter it is evidently kept very dry, while the precipitous slope and gravelly soil ensure perfect drainage in summer. This plant may be L. Wallichianum, or a variety of it. (K.W. 6428). In the valleys were many Acanthaceae in flower, and two common species of Buddleia ; often the boughs of the trees were bulging with Orchids.

On February 20 we did a short stage to the summit of the last big ridge, and arrived in the afternoon near a village, the first we had seen since leaving Trashigang. We found the headman in a peevish frame of mind, superintending his flock, who were mending the road. Our coolies, therefore, put down their loads, and announced their intention of returning, nor could we persuade them by bribery or corruption to march another step ; to do them justice, they were within their rights in refusing. As it was quite early, and India was a bare twenty-five miles away, we suggested to the peevish headman that he should provide transport on the spot, to enable us to do a few more miles before dark. To this he rudely replied with the Tibetan equivalent of "Who the blank blazes are you ?" and announced that he was supplying no coolies, either now, or next day, or next week. Deadlock. After a further exchange of rudeness, we announced our intention of going on, coolies or no coolies, and, if necessary, marching all night till we reached the frontier. Dick was to come with us, Sunny Jim was to remain behind and look after the baggage till we could send help. We then put food in our haversacks, rolled up a blanket apiece, and prepared to depart—we were not bluffing, but we had effectually called the peevish headman's bluff. He suddenly remembered that the jungle was full of tigers ; but we told him we liked being eaten by tigers, though we took the precaution of adding a gun to our baggage, and were just starting, when the headman's mercury fell to zero, and almost with tears in his eyes he begged us not to go, promising anything if only we would stay the night.

All we wanted was coolies for next morning, and the bargain was soon struck. Next day we started down the spur, and after an exasperating march, in which three-quarters of the coolies fell out, reached the valley below at nightfall. We were still some miles from India.

Next morning we started off down the forested glen on what we fondly hoped would be our last march, for the sky had cleared, and the gloomy and rather cold weather of the last few days had turned to the hot drought of Bengal. We had not gone far when we were met by two *sais* leading saddled ponies, which they invited us to mount ; and half-an-hour later we arrived at the camp of His Highness the son-in-law of the Maharaja of Bhutan. Here we halted for a little light refreshment of brandy and cream-crackers before pushing on to the last village, Devangiri, which overlooks the plains. His Highness lent us ponies and called up a fresh relay of porters ; and we gave him one of our tents and an electric lamp, thereby making him our friend for life. In the afternoon we reached Devangiri, and could see the plain of Assam below, dim in the haze ; we could have reached the frontier before nightfall, but the porters could not stay the course, so we spent one night in Bhutan. February 23 dawned at last, and we raced down the hill, and soon after mid-day stepped out of the leafless, monsoon forest on to the open plain. A sentry challenged us, and next moment we stood on British territory. A motor was waiting for us, our bedding was piled on, and at four o'clock we started for railhead twenty-four miles away ; our heavy kit was to follow in bullock carts during the night.

It was just dark as we came into Rangiya, and saw the red lights of the Assam-Bengal railway ahead. Arrived at the station we made up our beds on the waiting room floor and ordered dinner, which, of course, consisted entirely of curried chicken. Had anyone asked us what was the most wonderful experience of that famous night, I think we should have replied, "a clean table cloth and a bottle of beer."

Next day the Assam mail came in during the afternoon (there is only one train a day, each way), and we boarded a compartment with two Englishmen who were going home on leave—the first white men we had seen for nearly a year ; and on the 25th we reached Calcutta. The journey was over. *F. Kingdon Ward.*

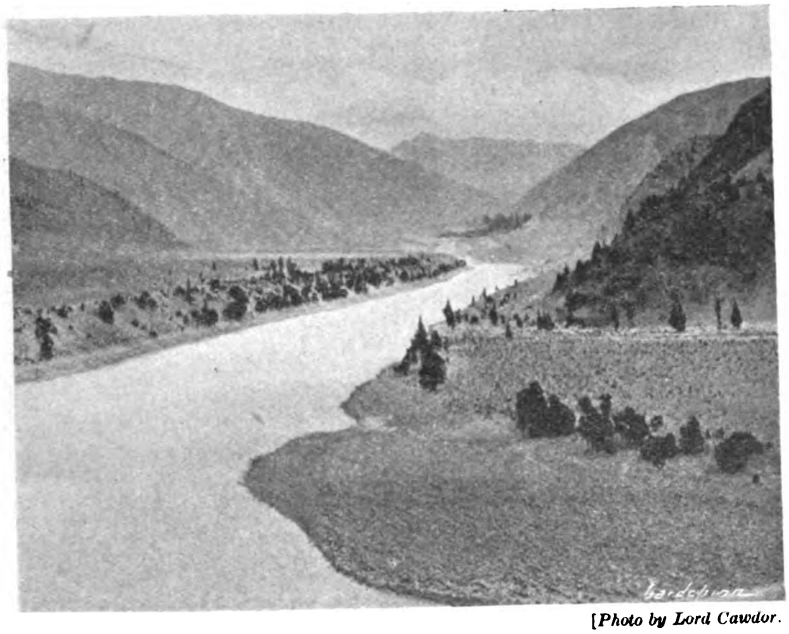
NOTES FROM EDINBURGH.

The approach of spring is indicated by the flowering of Rhododendron moupinense in the rock garden at Edinburgh, and R. parvifolium, with deep, pink coloured flowers, and rather a straggling habit of growth, is also in flower. Saxifraga Burseriana is flowering, together with a number of its varieties, the best of which just now are S. Burseriana major, and S. Burseriana tridentata. The variety Gloria appears to be slower in opening its blossoms. Primula Winteri is in flower under the protection of an overhanging rock, although pot plants, enjoying the shelter of a cold frame, have been in flower for some time. Another interesting species in flower in the same frame is P. Palinuri, with rather thick leaves and deep yellow flowers. In a cool greenhouse, the dainty P. malacoides, together with a white double-flowered variety which goes under the name of P. malacoides alba fl. pl. are both in bloom.

Between the stove houses the graceful Galanthus nivalis robustus has been flowering for some time, and doubtless the shelter and warmth afforded by the houses are responsible for its appearance in advance of the type, of which it is but a larger edition. In an adjacent bay, another little bulbous plant, Scilla amoena, is very pleasing ; it is a pretty, blue-flowered plant, with pendant blossoms.

Around the base of a Lime tree the Winter Aconite is beginning to form a golden circle. This admirable little plant has long been a denizen of our gardens, being introduced into this country in the sixteenth century, and it was figured by Gerard in his famous *Herbal* under the name of "Winter woolfesbane (Aconitum hyemale)." Like Crocuses, Snowdrops and other bulbous plants which flower in early spring, the Winter Aconite is seen to best advantage when planted in grass.

A few flowers of Lapageria rosea have appeared, and in a corner of the Rhododendron house, the white variety, L. rosea alba, flowers unobtrusively. A native of Chili, Lapageria rosea was introduced into this country in 1847, when a plant was sent to Kew. Messrs. J. Veitch and Sons later received plants through their collector, Thomas Lobb. In 1849, a figure of the species appeared in *Bot. Mag.*, t. 4447, which was prepared from herbarium specimens aided by coloured portraits of the plant in its native habitat. The generic name was given in compliment to Josephine Lapagerie, wife of Napoleon Bonaparte. A hybrid between Lapageria rosea and Philesia buxifolia, raised by Messrs. Veitch and Sons was described and figured by Dr. Maxwell T. Masters, in *Gard. Chron.*, 1872, p. 358, as Philageria Veitchii. Unfortunately, this interesting bigeneric hybrid appears now to be almost lost to cultivation. The interesting little Camellia cuspidata is flowering in the corridor, where it is trained, espalier fashion, on the wall. The white flowers, with their golden stamens, although not large, are attractive, and the dark, glossy-green foliage is extremely neat. If the flowers were larger there is no doubt this species would commend itself to a wider public. Quite a good display was made recently by Luculia gratissima, a well-known garden plant, and much valued for its pink flowers which it produces so freely. Its relative, L. Pinceana, does not appear to bloom so freely. A very excellent flowering plant which is rightly given considerable space on the wall in the corridor is Cestrum Newellii, a species which has previously been included in the genus Habrothamnus. At this time of year it makes an exceedingly attractive display of its fine red flowers. It will shortly be joined by other members of the genus. Cestrum elegans is quite a distinct species with dark green foliage and deep red flowers. C. aurantiacum has smoother leaves than the other two, and produces a mass of orange flowers, which are succeeded by white fruits. The finest member of the genus is C. Smithii which smothers itself with pretty pink flowers, which give place, later, to fine, dark red fruits which are produced in equal abundance.



[Photo by Lord Cawdor.

FIG. 74.—CAPT. F. KINGDON WARD'S EXPEDITION: JUNIPER TREES AND SAND DUNES IN THE TSANGPO VALLEY, NEAR TSETANG.

In one of the stove houses Napoleona cuspidata is in flower. This is more curious than ornamental, as the pink and white flowers sit so closely on the stems and branches that they are mostly concealed from view. The flowers are produced quite freely, and in themselves are very pretty. The genus belongs to the family Myrtaceae, although the structure of the flower is such that, at first sight, one would be puzzled to place the plant in its proper family. In the other stove house a display of Centradenia floribunda has been maintained for some time, and a good effect was produced by a few plants of Begonia socotrana. *Robert H. Jeffers, Edinburgh.*

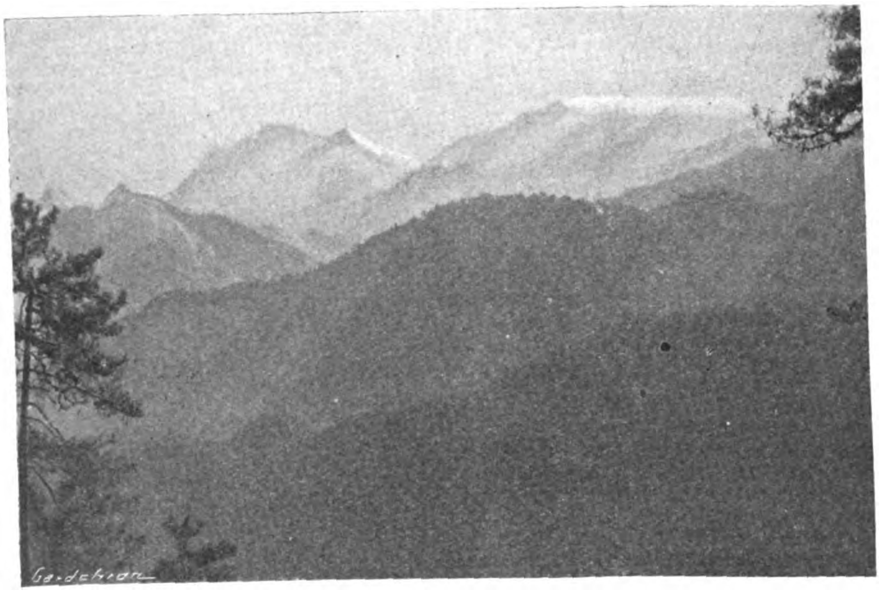


FIG. 75.—CAPT. F. KINGDON WARD'S EXPEDITION: THE LAST OF THE HIMALAYA.

NOTES FROM WISLEY.

The duration of the flowering period among shrubs is very variable. By some, a long period of bloom is maintained by a succession of flowers while others remain in flower by reason of the persistence of their blossoms. In the case of Hamamelis mollis the petals, contrary to their appearance, are remarkably tenacious. A flowering twig will remain fresh and fragrant in a jar of water for three weeks, and plants which I mentioned as being in flower at Wisley a month ago are still blooming.

In addition to Hamamelis many other shrubs are now flowering in the gardens of the Royal Horticultural Society, such as Pieris japonica and Skimmia japonica. Female plants of the latter still retain their glossy, scarlet fruits. The early-flowering Rhododendron dauricum is also in bloom, and unless the weather is unfavourable, there should be a particularly good show of Azaleas in the wild garden this spring.

In the field garden, Erica darleyensis, which has been flowering well throughout the winter, seems likely to last for some time yet, and many varieties of Erica carnea are now becoming conspicuous; among the best of these are King George, Queen Mary and James Backhouse, in addition to which are the white-flowered Erica carnea var. alba and some purple-foliaged varieties of the same species, such as E. c. atro-rubra and E. c. Vivelli, with bells more elongated and of a deeper crimson than those of the type. A purple-leaved variety of Erica mediterranea is also in flower in company with the dwarf-growing E. m. nana and E. m. hibernica.

The alpine house is now full of flowers, a large proportion of which is produced by Saxifrages derived from the Kabschia Saxifraga Burseriana. Of the glorified editions of the type S. Burseriana major and S. B. Gloria may be mentioned, while a yellow-flowered variety is seen in S. B. sulphurea. S. B. tridentina is distinguished by the erect arrangement of its petals, and S. B. speciosa by the slight crenation of its very large petals, but perhaps the prettiest and most distinct variety of all is S. B. crenata. This shows a very regular and marked crenation along the outer margin of the petals, and is still further distinguished by its darker foliage and the dark red stems and calyx which render the flower equally, if not more attractive when viewed from beneath. A hybrid between S. Burseriana and S. apiculata is S. Bursiculata, whose flowers are white. Several pretty little pink-flowered Kabschia hybrids are now blooming, such as Riverslea, Brenda, Elysum and Perle Rose, the flowers of which are of a more rosy pink than those of preceding kinds.

Other bright attractive plants in flower in this house are Iris reticulata, Soldanella montana, Morisia hypogaea and some double yellow Primroses.

The Crocuses in the frames near the alpine house are nearly at their best, and one or more varieties of at least fifteen distinct species may be seen in flower Many of these remain in flower for a long time, as, for example, Crocus Korolkowii, which has now been in bloom for four weeks. Some of the most fascinating are varieties of C. chrysanthus, many of which bear well-chosen and descriptive names, such as Silver Pheasant, Golden Pheasant, Lapland Bunting and Bumble Bee. There are also some pretty forms of Crocus Sieberi, C. corsicus and the deep orange C. aureus. Many of these are in flower in the open at the foot of the rock garden, where a deep yellow-flowered variety of C. chrysanthus, named fusco-tinctus—owing to the buff colouring on the back of the outer perianth—is in bloom.

Spring blossoms will soon be appearing all over the wild garden, and already there are large numbers of flowers of Hellebores, Snowdrops and Leucojum to be found, and the giant-flowered variety of the latter, named Wagneri is much in evidence. *J. E. G. White.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

LILIES FROM SEEDS.

UNTIL comparatively recent times the advocacy of the systematic propagation of Lilies by seeds has been a thankless task, and waste alike of breath, ink and paper. Here and there some enthusiastic amateur of the past made a practice of raising Lilies by what has always seemed to the writer the most natural way of raising them, but the great majority of amateurs and traders seems always to have been content to pursue the cultivation of Lilies by means of bulbs.

In a paper read at the Royal Horticultural Society's Conference on Lilies in 1901, the late Mr. F. W. Burbidge urged the more frequent raising of garden Lilies from seeds. "We want," he said, "at least one cultivator to do for our garden Lilies what Mr. Engleheart has done for our Daffodils, and I think we should then hear far less of Lily failures and of the Lily-fungus disease. Apart altogether from variations in form and colour, we shall be able to obtain healthier and more permanent stock bulbs from seedlings as raised at home under cultivation, than we shall by the almost invariable planting of imported bulbs."

In the main Mr. Burbidge was undoubtedly right in his conclusions, but that he was alone among his contemporaries is clear from the fact that the paper in question[*] contained the only reference to the seminal propagation of Lilies at the Conference.

No doubt the prime difficulty confronting the would-be grower of Lilies from seeds has ever been the same, for while the bulbs of many Lilies are not always easy to obtain, the seeds are often even more elusive; but the difficulty is one of degree, and in the writer's experience is solved by persistence which ultimately brings its own reward. Of recent years the almost universal widening of means of communication has smoothed away many of the difficulties which formerly beset the cultivator of Lilies, while the constant exploration of Western China and the generosity of those concerned in it have made matters comparatively easy where the many new Lilies of that great country are concerned.

Apart from Duchartre, who made a critical study of the seeds of such species of Lilium as were available to him, Max Leichtlin was probably the greatest protagonist of the seminal propagation of Lilies in modern times. He had correspondents in all four continents, and from them received seeds of many genera, including Lilium. Leichtlin had an almost uncanny *flair* for raising plants from seed, and those which beat him must have been difficult indeed. He never subscribed to the dictum, enunciated to the writer by a well-known nurseryman many years ago, that growing Lilies from seeds was not worth while, and happily, that view, once held by many traders, has undergone considerable modification of late years. How far that fine modern species, L. regale, has contributed to the change of view is a matter of opinion, but their experience of the ease and rapidity with which that Lily will reproduce itself has undoubtedly led many plant propagators to try their hands with seeds of other Lilies.

The increasing interest in gardening and in the cultivation of plants, and the dissemination of information about their ways and needs, have not been without effect, too, on the change of view, and the knowledge that home-grown bulbs of Lilies are much to be preferred to those which are imported and necessarily more or less dried, and consequently weakened, is no longer confined to those who make a speciality of growing Lilies. Though not sufficiently important to be of serious moment to the country, the economic aspect of the case, too, is not without interest, for there does not seem any object in paying the traders of other nations for bulbs of the many Lilies which can easily be grown in this country.

Raising Lilies from seeds is not an operation involving any especial skill, and is child's play compared to the seminal propagation of some genera of plants. No heat is needed, for Lilies will not be hurried, and, in the writer's experience, undue haste only seems to defeat the end in view. Some species are quick to germinate and others habitually allow a season to elapse before they move, but the writer does not know if this is natural or due to a change of climate and environment.

The period of germination and the percentage of it undoubtedly depend in some measure on the nature of the harvest; if the seeds are well-ripened, the rapidity of germination and the resulting crop of seedlings is perceptibly increased. The harvest of 1921 provided an instance of this, and that of last year an instance in the contrary direction. In the main the writer has not found that adventitious aids to germination, such as the saturation of the seeds in a solution of iodine, permanganate of potash, etc., is of material benefit in the case of reasonably fresh seeds, and he has not tried it in the case of the old seeds. Given well-ripened seeds, there does not seem any marked loss of germinating power up to three years. After that the percentage of germination falls off. In the case of ten-year-old seeds of L. Henryi, the writer found that the percentage was only ten of the normal fresh seeds.

As a general principle, all Lily seeds may be sown when Nature sows them, that is, when the capsules open. In course of time the grower will learn which species germinate at once, which wait the turn of the year, and which lie dormant for a season. In a good ripening year, seeds of L. tenuifolium, L. pyrenaicum, L. longiflorum, L. regale, and L. philippinense var. formosanum, for instance, may germinate in two or three weeks, and if hard weather does not supervene, may finish the first season's growth before the turn of the year —not to be confused with the calendar end of the year. In that way a season is gained by early sowing. On the other hand, seeds of L. rubellum and L. japonicum, for example, among others, usually remain dormant for a season.

In practice, the writer has noticed that deep seed pans yield more satisfactory results than those of the usual shallow type, probably because the larger volume of soil in the deeper pans is less subject to atmospheric changes than that in shallow pans. On the other hand, earthenware pans six to eight inches deep are cumbersome, and though wood may be substituted for earthenware, it does not seem to yield such satisfactory results with Lilies as with seeds of some other genera.

As a rule, Lily seeds are sown at too shallow a depth. Max Leichtlin practised deep sowing with the seeds of most bulbous plants, and always covered the seeds of Lilies with from three-eighths-of-an-inch to half-an-inch of soil. Incidentally this practice has the merit that there is little chance of disturbing or washing up the seeds when watering, though that tendency may be counteracted by using a hand or knapsack sprayer in place of the time-honoured watering-can, for no matter how well the rose of the latter fits the spout, it is all but impossible to avoid large drops of water falling on the pans.

When a large number of pans has to be dealt with in frames or houses, the latter can be fitted with vapourising nozzles connected to a pipe with water under pressure from a main or tank, and in that way watering is reduced to a simple operation involving no more labour than that of turning on the valves. Where mist spraying is practised, the water is so broken up into aqueous particles that its temperature does not seem of vital importance, but with watering cans it should always "have the chill off." The writer has known the growth of thousands of Lily seedlings to be seriously checked by the thoughtless use, in spring, of cold water. Watering at dusk in summer seems to have decided advantages over morning watering.

The nature of the compost used for Lily seeds is all important, and happily there is little need for experiment in that direction, for though the proportions of the ingredients will be varied at the whim of individual gardeners, those which yield the most satisfactory results are known. The basis of all such composts is loam, and though no word is possibly more misused, to the Lily grower it means broken down old turf, free of lime and without stones. If this is mixed with an equal bulk of broken down humus, free of sticks, and half the bulk of grit, with a powdering of charcoal dust, the result will be as suitable and sweet a medium as any raiser of Lilies can wish to have. But much depends on the kind of grit used; fine granite or gravel is useless as it is non-absorbent, and except hard sandstone, there is nothing to equal broken down red earthenware in the form of garden pots and roofing tiles, or soft red brick.

This material has been much used in the past in the manufacture of concrete paving slabs, and of late years has been largely employed in the construction of hard tennis courts. It is obtainable from any brickworks equipped with crushing machinery, and has the inestimable advantage that it is porous and that its colour enables the user to see what he is doing with it, as it were. The material can be crushed to any size, but if the cultivator takes everything that comes from the crusher which will pass a three-sixteenths inch mesh, he will have the right proportion of fine and coarse grit; it should be half-and-half.

For humus, leaf-mould is usually employed because, no doubt, it always has been employed, but it usually harbours a percentage of weed seeds and it is difficult to rid it of all trace of the sticks which so often develop the fatal white, thread-like fungus. Peat moss dust, which the writer has had on trial for some years at the suggestion of Mr. Maurice Prichard, seems to have several advantages over leaf-mould, and not the least is its apparent sterility. Whatever form of humus and grit is used, intimate mixing with the loam is essential, or the result will be unsatisfactory.

At this time of day there is no need to labour the advantage of soil sterilisation, but except for those with steam plant, complete sterilisation is hardly possible. Dry heat is useless, too, for though it serves for loam, one cannot apply such heat to leaf-mould without reducing it to powder. With peat moss dust and crushed brick no sterilisation is needed, and there only remains the loam, which can be partially sterilised with carbon bisulphide, a deadly but convenient poison gas. Sterilised soil is much less subject to green mould and Liverwort than untreated soil.

Though not always exercised, meticulous care in the technique of seed sowing brings its reward; for the drainage of the pans, for instance, the coarser siftings of the broken brick are ideal, and a square of old sacking over the drainage is a far better covering than the customary layer of leaves.

---

[*] *Jour. Roy. Hort. Soc.*, 1901, p. 388.

It should never be forgotten that for the seeds of calcifuge Lilies the compost must be free of any trace of lime. Leaf-mould and loam should be always suspect until tested, though peat moss dust and broken brick, provided there is no mortar with it, carry a clean sheet. Testing for lime is merely a matter of pouring a few drops of acid—sulphuric acid from the nearest electric accumulator, or "spirits of salts"—on to the compost; any bubbling of gas indicates the presence of lime.

Once in sight, seedling Lilies may be handled with impunity, provided, and the point is all important, the roots are not broken. They may be moved if necessary to other quarters without hurt and but little check. Some species of Lilium such as L. giganteum, L. cordifolium, L. canadense and L. monadelphum, do not show their cotyledon above ground in the first season of growth, and may deceive the unwary into the belief that they are dormant. If Lily seeds do not germinate in the second year after sowing there is no object in retaining them, but as a measure of precaution the seeds should be examined, and if found fleshy to the test of the finger nail they may be left for another year.

Seeds of all Lilies may be sown out-of-doors, but those who wish to practice the plan in our climate will find it best to defer the sowing until March; even then the casualties are far heavier than when seeds are sown in pans or in frames, where some measure of protection can be afforded the seedlings from the underground and overhead risks to which they are exposed. Commercially, open-air sowing is doubtless desirable. *A. Grove.*

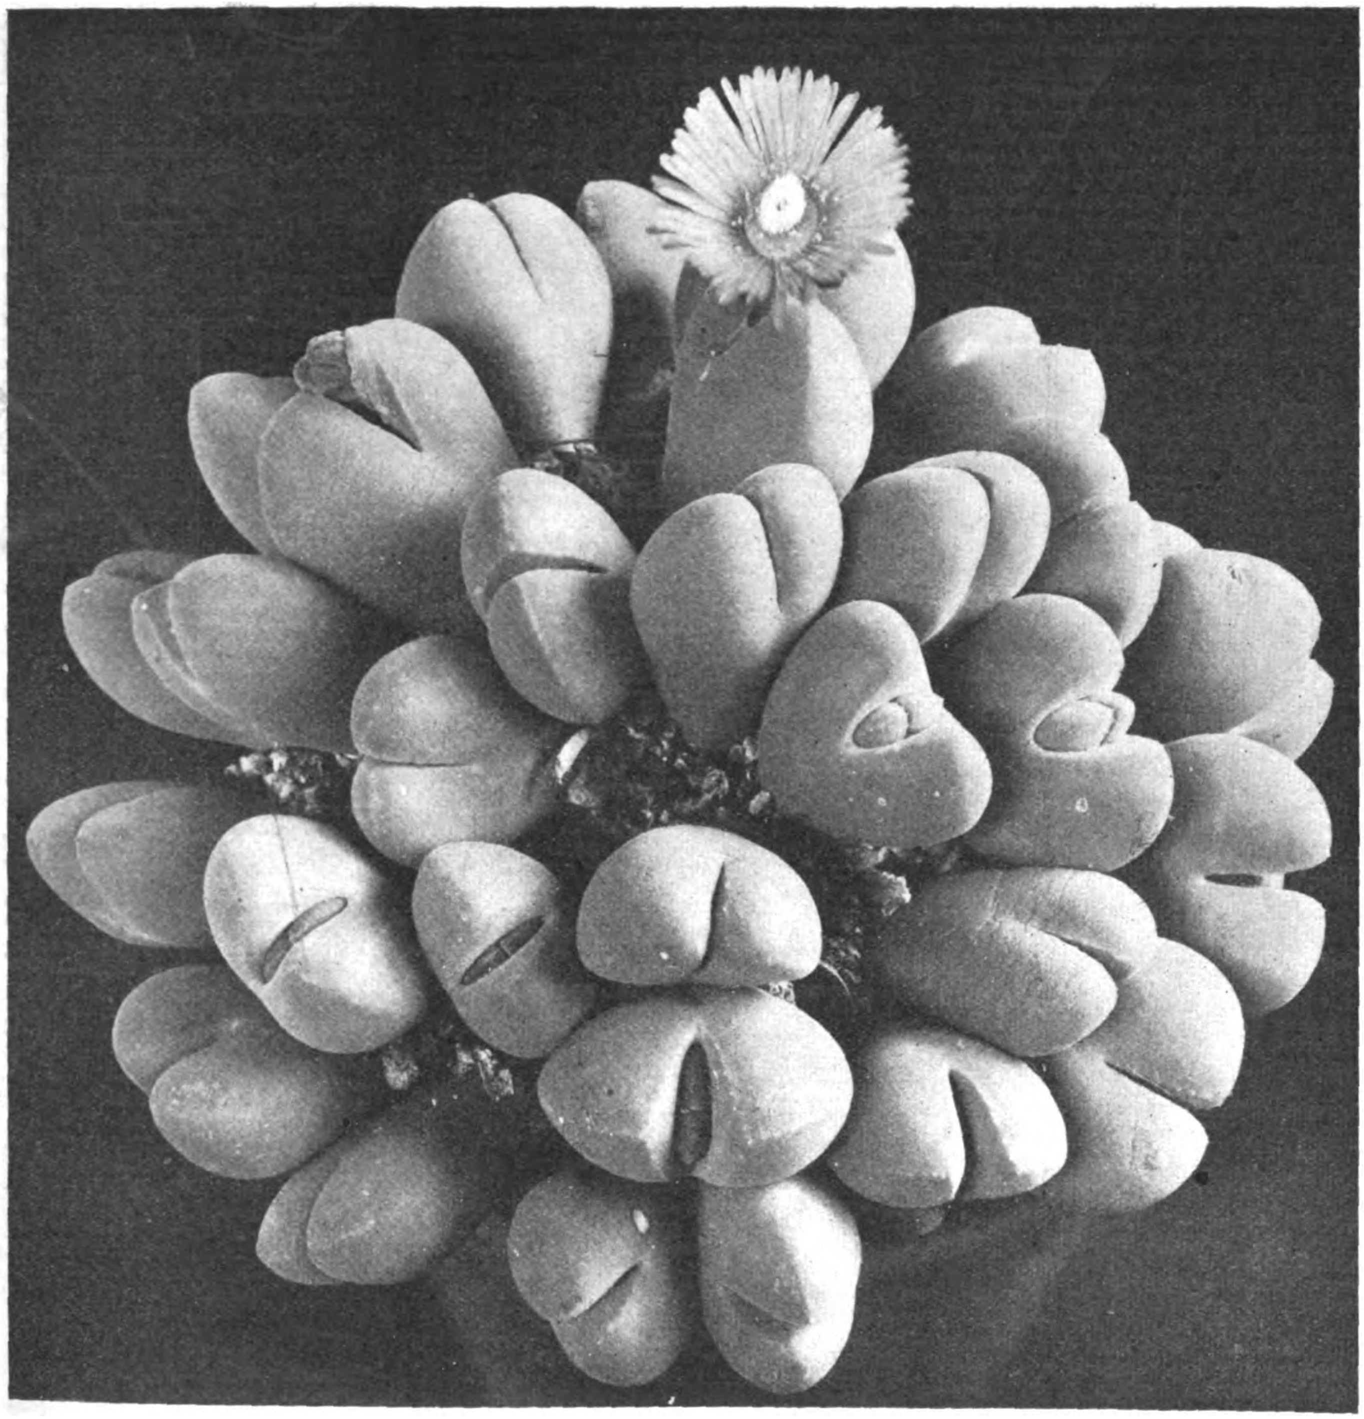

FIG. 76.—RIMARIA ROODIAE, N. E. Br.
Natural size. Flowers orange-yellow, opening at 3.30 p.m. and closing at 4.45 p.m.
Photograph taken at Vereeninging, September 6, 1925.

MESEMBRYANTHEMUM.

(*Continued from p.* 135).

2.—R. dubia, N. E. Br. Habit just the same as that of R. Heathii, with (under cultivation) the growths crowded upon short branchlets from the rootstock. Growths ½-1 inch long, 4-8 lines broad and 3-6 lines thick, obovoid, slightly compressed, with the two leaves of which they are composed usually more or less unequal in length and rounded at the apex, with the fissure between them 4-7 lines deep; surface smooth, glabrous, uniformly glaucous-green, without dots or other markings. Flowers and fruit unknown.

Mesembryanthemum fissum, N. E. Br., in *Journ. Linn. Soc.*, vol. XLV, p. 67, not of

Haworth. South Africa: Locality and collector unknown.

I give this plant a distinctive name with some hesitation, because its origin and its flowers are unknown, and it is so much like R. Heathii that there is nothing but size and a rather different green colour to distinguish it from that species. In my experience, under the same conditions, it increases much more freely and more rapidly than R. Heathii does, is always much smaller, and its growths are longer in proportion to their breadth and thickness. Seen side by side, the two plants certainly seem distinct, and when the flowers of R. dubia are known, definite distinctive characters may be found.

It has long been in cultivation and is known in gardens under the name of Mesembryanthemum fissum, and is the plant I have mentioned under that name in the *Journal of the Linnean Society*, as above quoted. For as the plant was known in gardens as M. fissum and agreed fairly well with Haworth's description, I at that time mistook it for that species. But I have since discovered that a drawing exists at Kew of the real M. fissum, which I had previously overlooked, and which demonstrates that species to be entirely different generically and specifically from this which I now name R. dubia.

3.—R. Roodiae, N. E. Br. (Fig. 76). Plant about 1½–2 inches high, consisting of a clump of growths crowded upon the short divisions of a deeply descending rootstock 6–8 lines thick. Each growth 1–1¾ inch high, with the basal part of the leaves united into a body ¾–1 inch long and ultimately withering into a sheath, their free part 4–9 lines long, 4½–10 lines broad and 4–9 lines thick, ovate or somewhat hemispherical, flat on the face, usually very broadly rounded on the back, with an obscure or distinctly evident keel, and with or without small teeth ¼–½ line long on the edges and keel; surface smooth, microscopically puberulous, green. Pedicels partly exserted, up to 9 lines long and about 2 lines thick, and together with the calyx puberulous like the leaves. Calyx 5-lobed; lobes 3–3½ lines long, broadly ovate, obtuse, 3 with membranous margins. Corolla only seen in a withered condition, 1¼ inch or more in diameter; petals about 5–7 lines long and ½–¾ line broad, linear, obtuse or notched at the apex, orange-yellow. Stamens numerous, collected into a cone, with some of the outer ones loose and spreading from the cone, apparently whitish. Stigmas 9-11, about 1½ line long, and about equalling the stamens, filiform, apparently of a darker colour than the stamens. Capsule when closed about 5 lines in diameter, flattened above and beneath; valves pallid within, with orange-brown expanding-keels. Seeds about ¼ line in diameter, whitish, with a pale brown nipple.

Bushmanland: Precise locality not stated, Mrs. E. Rood!

This species differs from R. Heathii by its greener colour, microscopically puberulous surface, the minute teeth on the edges and keel of the leaves, and orange-yellow flowers. It so much resembles a dried specimen in Kew Herbarium collected by the late Professor Pearson (No. 4071) at Enriet in Little Bushmanland, that at first I thought the two might be specifically identical, but I find the structure of the fruit of the two plants is so different that according to the modern conception of genera they ought not to belong to the same genus. For Pearson's plant has a half-globose capsule whose valves have stout (not thin) entire expanding-keels, with narrow and very small wings; the cells have stiff (not membranous) cell-wings forming a roof-like (not flat) cover to them, with their outer ends turned back and resembling the mouth of a trumpet, and the opening is nearly closed by a large tubercle. There is nothing of the kind in the fruit of Rimaria! It appears to be a case of one genus mimicking another, of which there are many in the vegetable kingdom.

4.—R. Pole-Evansii, N. E. Br. (Fig. 77). Plant with usually only one or occasionally two growths to a rootstock, subglobose or Pear-shaped, up to 1¾ inch in diameter, with the fissure 3–7 lines deep, and the top obtusely rounded, with a faint keel, very firm in substance; surface distinctly or very slightly rugulose, according to the water supplied, glabrous, microscopically granulate under a strong lens, of a pleasing uniform pale dove-grey colour, with a faint yellowish or reddish tint, not dotted. Flower solitary, subsessile, with the calyx just exserted from the fissure. Calyx about 8-lobed; lobes 2–3 lines long, oblong, obtuse. Corolla about 15 lines in diameter, expanding at about half-past two in the afternoon; petals very numerous, in 3–4 series, ascending-spreading and imbricate, not spreading horizontally, 5-6 lines long, cuneately linear, obtuse, according to a drawing the outer are of a delicate pink, and the inner light yellow or yellow with pink tips. Stamens numerous, collected into a compressed cylinder or a slightly conical mass, yellow. Stigmas apparently about 12-15, filiform, longer than the stamens. Capsule, in the only example seen, elliptic in outline, 12 lines in its greater and 9 lines in its lesser diameter, convex and 2-edged below, slightly convex on the top, with about 15 valves and cells. Seeds very numerous in each cell, very minute, subglobosely obovoid, minutely tuberculate, pale brown.

Mesembryanthemum Pole-Evansii, N. E. Br. in *Journ. Linn. Soc.*, vol. XLV, p. 90 (July, 1920).

Prieska Division: Locality unknown, McLeod!

I place this plant provisionally under the genus Rimaria with considerable doubt, for I have not seen a flower of it at present, and the only capsule I have seen was accidently destroyed before I could examine its structure. The details given are partly compiled from drawings and photographs, one of which is here reproduced (Fig. 77), and partly from such remains of the flower as I could find on the capsule, and are therefore necessarily somewhat imperfect. Yet whether it belongs to this or some other genus it cannot be mistaken for any other known plant, being one of the most distinct and striking of the stemless plants of this group that I have seen, its size, shape and pleasing dove-grey colour always making it a very conspicuous plant when seen among other allied genera and species. In South Africa it flowers in May. It has a very meagre root-system and requires very little water. *N. E. Brown.*

(To be continued.)

ORCHID NOTES AND GLEANINGS.

ODONTIODAS.

The mating of the few species of Cochlioda with Odontoglossums has resulted in a new race of beautiful plants, now well-known under the name of Odontioda. This hybrid genus is another instance of a comparatively insignificant parent imparting its desirable colour in an enriched form to its progeny, to which the other parent has given size and strength.

The combination of Odontoglossum with Cochlioda is undoubtedly one of the greatest achievements of the hybridists during the past twenty years. Previous to the introduction of this resulting race the majority of the inmates of our cool Orchid houses produced flowers devoid of brilliant colouring, with the exception of the Masdevallias and Sophronites. When the first Odontioda was shown in 1904 it was at once seen there was a great future for such desirable Orchids. Since the first hybrid appeared there has been continual improvement in the size and shape of the flowers, and in the best of these the vivid colour of Cochlioda has been retained. Upwards of four hundred-and-fifty hybrids are recorded, and it will be obvious there is great variety in such a large number. On account of its bright colour, Cochlioda Noezliana is a parent of the larger number of these. This has been crossed with most of the largest and best Odontoglossums, both hybrids and species, and many of the finest primary hybrids have been used again as parents until we have reached in many cases the third and fourth generation.

Most Odontiodas produce large, handsome spikes of many flowers of a bright, almost scarlet, hue, which are fine for all decorative purposes. Odontiodas thrive under precisely the same conditions as Odontoglossums, but being home-bred plants, they have a stronger and more robust constitution, hence are easier to grow, and produce flowers in greater profusion.

For the production of cut flowers the primary crosses are the best, and there are sufficient distinct forms procurable for a nominal sum to satisfy the most fastidious. If grown in precisely the same way as Odontoglossums, as regards compost, temperature, potting, etc., success will be assured. *J. T. B.*

INDOOR PLANTS.

RIVINA HUMULIS.

The pretty red fruits of this plant are a great attraction and useful for conservatory decoration. Seeds may be sown now in a house with a temperature of 55° to 60°, and the plants from this sowing will be at their best during late summer and autumn. The plant flowers and produces its fruits continuously over a long period. If desired, old plants may be grown on for a second season, when they make fine specimens for standing in beds. The Rivina grows freely in any good potting compost and presents no serious cultural difficulties.

TRACHELIUM COERULEUM.

This blue-flowered exotic is very useful for conservatory decoration, and if seeds are sown at this time the resulting plants will prove very useful for furnishing the stages during late summer and autumn.

Plants retained from last year should now be shifted into eight-inch or ten-inch pots, in which they should make fine specimens for furnishing the conservatory beds during the summer. This useful plant only requires cold greenhouse treatment at all times, and thrives in any good potting compost. *J. Coutts.*

ABELIA GRANDIFLORA.

The hybrid Abelia grandiflora is one of the hardiest members of the genus in general cultivation. It is a late-flowering, evergreen shrub, with glossy, dark green leaves, from one inch to two inches long. The light pink, tubular flowers are borne in clusters at the tips of the growths of the current season. After the flowers fade, the persistent purple sepals are a conspicuous feature.

Abelia grandiflora requires a warm, well drained soil, and a sunny position. Cuttings of half-ripened shoots inserted over a moderate bottom heat root quickly. It is a useful decorative subject for the cool greenhouse. Plants grown in pots six inches in diameter flower freely. If planted out, and the slender branches are trained to a pillar, this shrub will grow twelve feet high, and smother itself with bloom from the base upwards.

CEROPEGIA WOODII.

This interesting member of the Asclepiadeae is a warm greenhouse herb, native of Nata It produces numerous long, slender stems clothed with fleshy, orbicular leaves, marbled with silvery white on the upper surface, Globose, spiny tubers about the size of Peas are scattered at intervals along the stems.

The flowers are curious in structure, pink in colour, tubular, with five dark segments which cohere at the apex. They are freely borne on the trailing growths and show to advantage when the plant is suspended from the roof in pans or baskets.

Cuttings of the lateral growths inserted in early spring will root in heat, and when established the plants should be grown on in a light open compost in a warm greenhouse or stove. *Fred W. Jeffery.*

HARDY FERNS.

Hardy Ferns offer a field of culture replete with interest and beauty, affording scope for the creation of charming scenes in every type of garden. No modern garden is complete without its Fernery. What could be more simple than turning an unprepossessing corner of the garden into a charming and interesting Fernery by judiciously arranging and planting it with some of the gems amongst our British Ferns?

Where ample space is available the possibilities are almost without limit, for the countless forms of beauty to be found amongst these beautiful plants are so extensive that it would be well-nigh impossible to make a collection of every known form even if one desired to.

A study of these plants in their native habitats will be helpful in the preparation of positions suitable for them. The home of indigenous Fern-growth appears to be Nature in unkempt state. Their cradle, the cool, damp dell or wood-ditch, where, beneath trees or rude-thorned Bramble, they rear their delicate fronds, free from the direct influence of the sun and beyond injury from winds from whatever quarter directed.

Some species like the damp, stagnant moisture which attaches itself to an old tree, ankle-deep in water, as with Aspidium spinulosum. Some prefer deep, moist, clayey loam, like the Lady Ferns, while in the native haunts the Bramble-shaded upland woods shelter Blechnum spicant. The longest and strongest fronds of the Royal Fern are to be found in fields of a moist nature where they defy the full sunlight and exposure which such positions experience. Others, again, Asplenium Adiantum nigrum and Ceterach officinarum for example, choose the apex of the dry rock for their native home. Cystopteris fragilis and Asplenium viride, on the other hand, affect the dampness near the hollow.

It will be gathered from these remarks that a particular preparation of the whole Fernery need not be aimed at, but that the object of construction and arrangement should be to give as much variation as possible to enable the planter to find a congenial home to meet the requirements of his various subjects. In surfacing the earth-work of Ferneries, boulders and blocks which are out of all proportion to the space at command are too frequently used. Abundant room should be left for Ferns to be so planted that they eventually cover all, from amongst which blocks and boulders simply project irregularly. Having fashioned the outlines and arranged the surface, planting may be done in March, and a goodly dressing of leaf-mould or other decayed organic matter should be applied, for the Ferns delight in this material.

It is a natural desire of the planter to make as effective a display as possible quickly, and for this purpose a quantity of the common indigenous species may be procured, and the whole area planted thinly with them. These comprise Aspidiums, Aspleniums, Polypodiums, and Scolopendriums, which are easily obtained. For placing in exposed positions, the common Polypody, P. vulgare, is very useful. It should be borne in mind that, with the exception of Scolopendriums, Polypodiums and some of the Aspidiums, Ferns are largely deciduous and in view of maintaining as bright and furnished an appearance as possible the evergreen kinds should be planted liberally. Attention must also be given, however, to the planting of the newer or rarer kinds, without which even the small Fernery will not be complete or possess the means of interest.

In all Ferneries some portions are more exposed than others, and in suggesting the following for positions in prominent fissures, it may be said that Bentham and Hooker's nomenclature is adhered to: Aspidium angulare grandiceps, A. cristatum, A. Filix-mas cristata, A. F.-m. furcans, A. F.-m. grandiceps, Polypodium vulgare cambricum, Scolopendrium vulgare digitatum, S. v. marginatum and S. v. sagitato-cristata. Lower down in deep soil and in damp and shady places should be arranged in prominent positions such abnormal forms of the Lady Fern as Asplenium Filix-foemina multifidum; A. F.-f. grandiceps and A. F.-f. Fieldiae. These make an interesting group as showing the wonderful sportive character of these elegant plants. Allosurus crispus, the Parsley Fern, gives variety by the differences existing between sterile and fertile fronds. Asplenium viride, a dwarf grower, is a good associate. Blechnum spicant imbricatum is useful for elevations in deep soil, while Cystopteris fragilis and Osmunda regalis cristata like deep, moist soil and positions not too shaded. Polypodium Dryopteris and P. Phegopteris, the much admired "Oak," and "Beech" Ferns, respectively, should certainly be included.

Though the shade of trees is desirable for Ferns, wherever an Elm exists it will be well to remove it before the Fernery is formed. The surface-rooting characteristic of the Elm is so great that it quickly impoverishes the soil, robbing it during dry weather of all latent moisture. An important feature of Ferneries is that, when made and planted, very little labour is required to keep them in order. Annual top-dressings of decayed vegetable manure in spring, and periodical cleanings during the growing season, form the greater part of the necessary work. After a year or two of growth some of the commoner, normal forms may be weeded out and planted on the outer limits, giving the rarer forms room to develop. *A. P. C.*

FIG. 77. RIMARIA POLE-EVANSII, N. E. Br.

(see p. 156).

VIOLETS IN FRAMES.

To obtain Violets of the highest quality it is essential that the plants should have liberal treatment when growing in their summer quarters.

The ground should be dug deeply, especially for the strong-growing single varieties, and enriched with well-decayed stable manure and a dusting of wood-ash, adding a sprinkling of lime later. Land which has been trenched previously for Sweet Peas is especially suited to Violets. Partial shade during the hottest months is an advantage.

The plants which have been growing in frames may be divided during April, and the rooted runners planted at distances varying from eight inches apart for the double varieties, to fourteen inches for singles. If attention is given to watering, the runners will soon become established and grow freely. Subsequent treatment consists in watering during dry periods and syringing after hot days. The soil between the plants should be stirred frequently with the Dutch hoe. Restrict the plants to a single crown, removing all runners and side-shoots as they appear. By the middle of September the plants will have completed their growth and be ready for transferring to the frames. These should be raised above the surrounding ground level, face south, and be tilted in such a manner as will ensure the maximum amount of light reaching the plants during the winter. A frame having two lights, each measuring six feet by four feet, will hold about forty-two plants of the variety Princess of Wales, or almost double that number of Lady Hume Campbell or Marie Louise.

When planting, retain as much soil as possible about the roots, thus obviating a severe check to growth. As the work proceeds, work in among the plants some old potting soil to which has been added a four-inch potful of bone meal and double that quantity of wood-ash to each bushel of soil. The soil should be made firm and have a decided slope towards the front of the frame.

Water the plants, and unless the weather is very bright and hot, leave the lights off entirely for a week or two. When these are placed in position air should be admitted by tilting them at the back and removing them entirely during spells of fine weather. Covering material should be at hand when severe weather is expected. If the plants should become frozen they should be kept shaded to ensure the thawing process being gradual, or harm will result. Stable litter placed around the frame will assist in keeping out frost, which, however, will do no further harm than check the plants in their flowering if precautions are taken to prevent sudden thawing. It is sometimes necessary to keep the frames covered for a week or two during continued hard weather.

During December and January very little water will be required, but with the arrival of warmer weather the plants will require frequent attention in this matter. Any decaying foliage should be removed and the soil stirred occasionally. By the middle of February a light top-dressing will help to strengthen the plants. This may consist of a mixture of sifted soil, six parts, to one each of bone-meal and wood-ash, and be applied at the rate of a peck to each light.

For the successful cultivation of Violets in frames, the need of plenty of fresh air is almost universally recognised, but one or two small growers I know never open their lights after planting except to gather the flowers. *Charles Hodgson, Acton Place Gardens, Acton, Sudbury, Suffolk.*

PLANTS THAT HAVE SUFFERED FROM FROST AT LA MORTOLA.

RECENT books dealing with gardening in the Riviera have seemed to make light of the difficulties and place all successes to the credit of the climate. But even in this favoured spot it has been necessary to cover plants with canvas, paper, Palm leaves, straw mats and Pine branches, and to make smother fires to protect plants against frost, of which we experienced 13° on January 13. Gardens which relied solely on colour for their charm have suffered badly, but where, as at La Mortola, beauty of form in trees and shrubs has not been neglected, there is no lack of interest or of beauty. I append a list of plants that have suffered from frost at La Mortola, as it may serve to impress upon Riviera gardeners the need of occasional protection.

Acanthus arboreus and A. mollis; †Agave attenuata, †A. Bergeri, †A caespitosa, †A. densiflora, A. flaccifolia, A. geminiflora, †A. Ghiesbreghtii, A. sisalana, †A. Wercklei, and A. Wildingii; Ageratum mexicanum, Aloe affinis, A. arborescens frutescens, A. Brunnthaleri, A. ciliaris, A. Dyeri, A. ferox, A. lateritia, A. plicatilis, †A. Salm-Dyckiana, A. Simii, A. succotrina, and A. supralaevis; Anona Cherimolia, Argyreia speciosa, Arundo donax.

†Begonia fagifolia, †B. macrophylla, B. manicata, B. miniata, †B. semperflorens, B. Rex and *B. weltoniensis; †Bougainvillea glabra, †B. Sanderiana and †B. spectabilis; †Bouvardia coccinea, Brachychiton luridus, and Buddleia madagascariensis.

Calendula officinalis, Calodendrum capensis, Camellia japonica, Cantua buxifolia, *Carica Papaya, Casimiroa edulis, Celastrus arbutifolius, Cestrum aurantiacum, C. lanatum, and C. nocturnum; Chlorophytum elatum, Chrysanthemum frutescens, *Cineraria stellata, †Colocasia antiquorum, Colquhounia vestita, †Cordia Franciscii and C. serratifolia; †Crassula rosularis, †Cussonia triptera, Cyperus alternifolius and †C. Pepyrus; †Cyphomandra betacea.

†Dahlia Maximiliana, †Datura arborescens, †D. chlorantha and †D. sanguinea; †Dombeya Cayeuxii and †D. Wallichii; Draceana Draco, Dunalia cyanea.

Echeveria gibbiflora, E. imbricata and †E. multicaulis; Echium callithyrsum, E. fastuosum, E. formosum and E. giganteum; †Erythrina Crista-galli, E. insignis and E. viarum; Eucalyptus Globulus, E. leucoxylon, E. marginata, E. melliodora, E. rostrata, and E. Stuartiana; Euphorbia abyssinica, †E. balsamifera and E. Regis-Jubae.

†Ferdinanda eminens, †Ficus comosa, †F. laevigata, †F. macrophylla, †F. religiosa, and †F. Roxburghii; *Fuchsia arborescens and F. triphylla; Furcraea Selloa.

Genista monosperma, †Gynura aurantiaca, †Hebeclinium ianthinum and H. macrophyllum; Hedychium carneum and H. Gardnerianum; Heliotropium peruvianum, Hexacentris coccinea, Hibiscus Rosa-sinensis and H. splendens.

†Iochroma coccinea, †I. grandiflora and †I. lanceolatum; Ipomoea Leari.

Jacaranda ovalifolia, Jasminum officinale,

†Kalanchoe coccinea, †K. marmorata and †K. somaliensis; †Kleinia Grantii and †K. neriifolia.

Lantana Camara and L. lilacina.

Mackaya bella, Meryta macrophylla, Mesembryanthemum aequilaterale, M. multiflorum, M. rubricaule, M. serrulatum and M. verruculatum; †Monstera deliciosa, †Montanoa bipinnatifida and M. tomentosa; †Musa Basjoo, †M. Ensete and †M. paradisiaca.

Odina caffra, Olmediella Betschleriana.

Pelargonium anthamanthoides, P. hybridum, P. inquinans, P. lateripes, P.Radula, P. roseum, P. scandens, P. vitifolium and P. zonale; Phytolacca dioica, †Pilea microphylla, Pithecoctenium buccinatorium and P. muricatum; †Poinsettia pulcherrima, Pteris longifolia.

†Reinwardtia trigyna, †Reseda odorata, †Richardia africana, †Rosa Banksiae and others in variety.

†Salvia albocaerulea, S. amarissima, S. augustifolia, S. elegans, S. farinacea, S. Heeri, S. mentiens and †S. Sessei; Schefflera Stelzneriana, †Sempervivum arboreum, S. FORESTRY.

THE INFLUENCE OF PROLONGED DAYLIGHT IN THE VEGETATIVE SEASON ON THE QUALITY OF CONIFEROUS TIMBER GROWN AT HIGH LATITUDES.

(*Concluded from p.* 139).

IN Coniferous timber good quality depends not only on the absolute narrowness and uniformity of the annual wood rings, although this is of paramount importance, but also on the relative proportions of the thin-walled, comparatively weak, tissue of the spring wood, and the thick-walled, dense, strong tissue of the autumn wood, which together compose them. Pfeffer states that "nothing definite is known as to the causes which determine the anatomical differences between spring, summer, and autumn wood . . . the annual series of changes in the structure of the wood is the result of a complex correlative reaction, which we are not at present able to resolve into simpler factors."* Be this as it may, we know that when growth in thickness is rapid in Conifers there is generally a preponderance of spring wood, and in our British-grown Coniferous timber we find that, owing to mistaken ideas regarding its silvicultural treatment, this spring wood usually predominates in plantation timber. This is more especially true of the common Spruce, the silvicultural characteristics of which never seem in the past to have been properly understood, although it is a tree which, generally speaking, is well adapted to our insular conditions, but more especially to the more mountainous, western parts of the country, as isolated, untended stands occasionally show. Superior quality in Coniferous timber, then, primarily depends on the weak, spring wood being reduced to the lowest possible limit, and the strong autumn wood being relatively increased. This disposition of the wood elements can, of course, be controlled up to a certain point by the adoption of silvicultural methods which will tend to curb growth in spring by retarding its start as much as possible, and thus imitate nature's methods in high latitudes. But in low latitudes this has its limitations, and the great difference between the conditions as regards the duration of daylight in the growing season in this country and those of the great forest regions of Northern Europe precludes the possibility of our ever being able to produce the fine qualities of Coniferous timber, even when grown in the same way, which we import from these parts. We may take the data furnished by Mr. Farquharson to Dr. Hunter as being indicative of the rate of growth in girth of Scots Pine under natural conditions in the north of Scotland, but this compares unfavourably from the quality point of view with North Russian and Finnish samples, in which the number of wood rings to the inch is at least double what it is in the Invercauld sample. And as for Russian Larch, to try to produce a quality of this in Britain comparable to what we import from Archangel would be quite impossible. Like the Scots Pine, the Larch is a strong-light-demanding tree, and any attempt to grow it in sufficiently close forest here to produce as fine, close-grained timber as the imported material would meet with immediate disaster.

When we come to deal with the growth in girth of the trees forming these North Russian and Finnish forests, so far as the volume of timber goes it would seem to compare very unfavourably with plantation timber in this country. Mr. Farquharson stated in his communication to Dr. Hunter that the 214 years old, naturally-produced Pine which he measured, had a diameter corresponding to that of a planted Pine of fifty years of age, that is, at fifty years of age the naturally-grown tree would be about one-fourth of the diameter of a planted tree of the same age. He mentions that these self-sown trees were free from side-branches to a height of fifty to sixty feet before they acquired the diameter of a foot, but nothing is stated about the height of the planted trees. Now, assuming the diameter of the former to be only one-fourth of that of the latter at the same age, and that the height and form factors of both were approximately the same, the volume of the self-sown tree would be one-sixteenth of that of the planted one. But this would probably be a very unfair comparison, for if the diameter of the self-sown tree was two-and-a-half feet at the age of 214 years, it is more than probable that the trees which Mr. Farquharson refers to as being "free from side-branches of any size, to the height of fifty or sixty feet, before they acquire the diameter of a foot" would not only be taller, but would have a much better form factor than the planted trees at the age of fifty years. But at the age of fifty years there would also be a much greater number of stems on a given area in the case of the self-sown trees, and therefore the difference in the volume of timber per unit of area would not be much less, if actually less, than the difference between the volumes of individual self-sown and planted trees. However this may be, there can be no doubt whatever that the timber of these self-sown trees, of which some of the "master-trees" were four feet in diameter, and "fit for the finest deal board," must have been of very superior quality as compared with that of the planted trees, for there is a vast difference from this point of view between fifteen annual rings to the inch, as we have in the self-sown tree measured by Mr. Farquharson, and ten rings to three inches, as we have in the planted one grown on the same ground, with, no doubt, also a much larger proportion of weak spring wood in the latter. Moreover, in his statement that the self-sown trees were "straight, and free from side branches of any size," and that when "the master-trees acquire some space around them, then they begin to shoot out in a more bushy manner at the top, gradually losing their spiral form, increasing afterwards more in size of body than height," not only have we in this dissertation of Mr. Farquharson's evidence of the production of fine, clean timber, but a lucid exposition of some of the soundest principles of silvicultural science, such as one might expect to find in the most up-to-date works on the subject at the present day.

* Plants killed. † Foliage ruined.

* *The Physiology of Plants*, Vol. II., p. 215.

RESUMÉ.

The higher the latitude, the weaker is the intensity of the sunlight and the shorter the season of growth, and correlated with this falling off in the intensity of the solar radiation there is a progressive descent from the luxuriant vegetation of the tropical zone to a state of *nanism* at the highest latitudes at which the seed-bearing plants occur. The phenomenon of *nanism* is, of course, also met with at high altitudes in the tropical zone, where the atmosphere is much attenuated, and where the sunlight is at its greatest intensity, for, as Warming points out, "intense light by day and cold by night co-operate at high altitudes in retarding growth; prolonged, though weaker, light and lower temperatures in Polar lands have the same effect." But there is a vast difference in the circumstances which bring about *nanism* in these two regions. In the tropical zone the daily duration of the intense sunlight, which contributes so much to the production of *nanism* at high altitudes, varies but little at any season, hence growth is practically continuous all the year round. At the Polar limits of plant life, on the other hand, the whole of the annual supply of sunlight is received in the summer half of the year, and such a large proportion of this is required to melt the snow and ice which have accumulated in the long winter season, as well as to raise the temperature of the soil sufficiently to enable plants to function, that the growing season is restricted to a very short period. But this retardation of growth is one of the most important factors in the production of high quality in the Coniferous timber which comes from these high latitudes, for the excessive development of weak "spring" wood, so common in inferior qualities of Coniferous timber, is thereby prevented, and the production of dense, strong "autumn" wood is encouraged.

But in the growing season at these high latitudes, the chemical intensity of the sunlight is very substantially increased over what it was at the vernal equinox, and thus the heat requirements of the plants are met, or more than met, while their light requirements are greatly over provided for. When the *optimum* light requirements of a species are met, any increase over this amount is of no further advantage to it, and the excess can only be utilised by an increase in the number of individuals. And this is what we find in these naturally-reproduced Coniferous forests, where Nature makes provision for the utilisation of this excess of sunlight by providing a superabundance of seedling plants, and allowing them to contend among themselves for this sunlight, and to settle the question of the survival of the fittest among them in their own way. It is in such circumstances as these that, in Finland, in the neighbourhood of the arctic circle, where the chemical intensity of the solar rays is comparatively low, but where the daylight at the middle of the growing season is practically of perpetual duration, according to M. Frederiksen, the "long, healthy pines, as straight as the most perfect columns," are found. And if proof that the surplus sunlight received in these high latitudes in the growing season is used in this way were required, one has only to point to the timber of the Archangel Larch, which is imported into this country, to furnish it. For, as has been mentioned, to attempt to grow a light-demanding tree like the Larch in this country in sufficiently close formation to produce narrow-ringed timber of this sort would be impossible.

At the latitude of 64° N., which practically bisects the great forest region of Finland and Northern Russia, the duration of the daylight at the middle of the growing season is approximately as 4 to 3 at the latitude of Edinburgh (56°), and 3 to 2 at the latitude of London (51½°). Assuming the light requirements of the species to be constant for all latitudes, this means that approximately one-third more stems could be accommodated on a given area at the latitude of 64° than at 56°, and one-half more than at 51½°.

The mainland of Great Britain lies between the latitudes of approximately 50° and 58½° N., and the difference in the duration of the daylight at the middle of the growing season at the extreme north and south ends of the island is about two hours daily. The effect of this upon the quality of Coniferous timber, provided it is grown under similar, and proper, silvicultural methods, must be appreciable, and points to the conclusion that the northern part of the island is better adapted to the production of Coniferous timber of good quality than the southern part. It would, however, be impossible under any circumstances to produce in this country, even in the north of Scotland, Coniferous timber of a quality equal to that which is produced in Finland and Northern Russia. *A. D. Richardson, Edinburgh.*

ORIGIN, EARLY HISTORY AND DEVELOPMENT OF THE POTATO.

(*Continued from page* 120.)

INTRODUCTION INTO OTHER COUNTRIES.

While in a book published in Italy in 1584 no mention is made of the Potato, we know from Clusius that it was taken from Italy by the Papal delegates to Belgium, where some tubers were received by Philipp de Sivry, Prefect of Mons, who, in 1588, sent two tubers to Clusius in Vienna. Clusius, in turn, sent specimens to various botanic gardens in Germany. Bauhin grew Potatos at Basle, Switzerland, in 1596, and from there the Potato passed into France. The first mention of it in French literature is in 1600 by Oliver de Serres in his *Théâter d' Agriculture et Mesnage des Champs.* According to Krichauff, the Potato was first placed on the royal table of France in 1616. In Germany the Potato made much more rapid progress than in France. Sweden was late in adopting the Potato. In India it would appear to have been grown during the governor-generalship of Warren Hastings (1772-1785). With regard to North America, the evidence is that the Potato was unknown to American agriculture either in the sixteenth or seventeenth centuries, and that it was not until the early part of the eighteenth century that it was first introduced. According to Bailey,[*] the tuber was not brought into cultivation in New England until the arrival of the Presbyterian immigrants from Ireland in 1718. In all countries there appears to have been strong opposition to the introduction of the Potato; some objected to it on account of its presumed harmful effect on the mind, and others because it was not mentioned in the Bible! Frederick the Great of Prussia and his father found it necessary to use compulsion to secure its growth, but although the royal decrees had their effect, it was the famine caused by the Silesian wars, especially the Seven Year's War, which established Potato culture in Prussia. In Russia, the prejudice was so strong that the tubers were referred to by peasants as the "Devil's Apples.[*]" In France, also, the Potato was at first regarded with no favour; in fact, it was commonly spoken of in that country as food fit only for animals and poor people. It was Parmentier, an apothecary, who really introduced the cultivation of the Potato into France, and it was not until his time that the prejudice was removed. Parmentier was a prisoner of war in Germany during the Seven Years' War: during his confinement he was fed on Potatos and learned to like them. In 1771,[†] a high prize was offered by the Academy of Besançon for the discovery of a new food which would fill the place of cereals in time of famine. In the succeeding year Parmentier presented to this academy his celebrated memorandum on the culture of the Potato.[‡] Louis XVI gave him fifty morgen of land to plant them on. When showing the first flowers of his Potatos on August 25, 1785, the king used them as a buttonhole bouquet, Queen Marie Antoinette had them in the evening in her hair, and at once princes, dukes and high functionaries went to Parmentier for such flowers. All Paris talked of nothing but Potatos and the cultivator of them.

EARLY HISTORY IN BRITAIN.

According to Sir Joseph Banks, Sir Robert Southwell, president of the Royal Society, informed the members of the Society at a meeting on December 13, 1693, that his grandfather introduced the Potato into Ireland, having obtained it from Sir Walter Raleigh. It would appear, therefore, as practically certain that the entry into Ireland took place very shortly after the Potato had been brought to England. Louden[§] states that the Potato was first planted by Sir Walter Raleigh in his estate of Youghall, near Cork, Ireland, and was, according to Gough in his edition of *Camden's Britannia*, 'cherished and cultivated' for food in that country before its value was known in England. Gerard planted Potatos in his garden in 1596, but he recommended them as a delicate dish and not for common food. It is stated that, owing to ignorance, when the Potato was first cultivated in Ireland, the fruit, *i.e.*, the berry, was regarded as the edible portion of the plant. It is reported in *The Gardeners' Chronicle*, 1882, that Sir Walter Raleigh's gardener, annoyed at the unpleasant taste of the berries, complained bitterly and asserted that the plant was not worth a place in his garden. However, when he proceeded to dig it out, he found the tubers concerning the merits of which he soon became acquainted. A similar story concerning some of Sir Francis Drake's friends appears in the volume for 1874.

For a long time, Potatos remained a dainty in Britain, and in a written book[||] for housekeeping kept by Queen Anne, wife of James I (1603-25), it is stated that a small quantity of Potatos were purchased at 2/- per pound. The Government, tried to push the cultivation of the Potato in 1663, but progress was very slow. Potatos are mentioned by John Reid in *The Scots Gardner*, Edinburgh, 1683, from which the following quotation is taken:—"Potatos being cut in as many pieces as you please, provided there be an eye to each piece, must be planted in March, five rows in a bed; plant not deep, neither in wet or stiff ground." In 1699, Evelyn recommended growers to plant

Potatos in their worst ground. It is a noteworthy fact that in English books on gardening of the year 1719, as in that by the famous nurserymen, London and Wise, the Potato is not even mentioned, and Bradley, who wrote extensively on horticultural subjects about the same time, speaks of them as inferior to Skirrets and Radishes. Only later in the eighteenth century did the Potato become better known and cultivated in Great Britain. According to Krichauff, they were chiefly found in the gardens of peers and rich men up to about 1784. However, Bradley in his *Complete Body of Husbandry*, published in 1727, recommends Potatos to follow Carrots and Onions in field culture, and it is to be assumed, therefore, that field culture was in vogue in England during the first quarter of the century, although perhaps to no great extent. In *Chambers' Cyclopaedia*, (1781), it is mentioned that the cultivation had been general for the "past forty or fifty years." *T. P. McIntosh.*

(To be concluded).

VEGETABLE GARDEN.

THE CULTIVATION OF THE PARSNIP.

THOUGH the Parsnip is not difficult to cultivate a fair amount of care is necessary if the crop is to be a success. It needs a rich soil, though not one which has been enriched with farmyard manure during the current season, for fresh farmyard dung predisposes the roots to forking.

I find it good practice to sow Parsnips on the site of an old Onion bed, Celery or Leek trenches. The only preliminary treatment given is to dig the soil thoroughly to the depth of one foot. Naturally, the time of sowing will vary in accordance with the situation of the garden. Here, in the south, we sow as near to the first week in March as the ground is fit for the reception of the seeds. I have sown earlier than that but never gained anything by it. In a garden in the north I used to sow Parsnips so soon after the third week in March as possible.

Drills should be drawn one-inch-and-a-half deep and fifteen inches apart, and the seeds should be scattered thinly in them. One ounce of seed will sow a row forty feet in length. When the seedlings are three inches tall they should be thinned to a distance of twelve inches apart. I feel it a duty to stress the importance of timely thinning, for if the seedlings are allowed to become overcrowded, no amount of after care will ensure the crop being a success.

The only cultural attention necessary until the crop is half-grown consists in the diligent use of the Dutch hoe, which conserves moisture, destroys weeds and aerates the soil. Feeding with concentrated fertilisers may be commenced at the stage mentioned, when stimulants may be applied once a week until signs of maturity appear in autumn.

Of the many fertilisers tried, I find none give better results than a mixture of superphosphate four parts, sulphate of ammonia one part, and sulphate of potash one part. These substances should be mixed and applied at the rate of half-an-ounce per plant. If the weather is dry, the fertiliser should be watered into the soil.

To secure fine Parsnips for exhibition holes should be bored six inches in diameter and two to three feet in depth and filled with a mixture of equal parts loam, leaf-mould and sand, riddled through a half-inch sieve. Five or six seeds are deposited in each station and the seedlings thinned to one. Obviously this system involves much labour and for the ordinary crop can only be justified when the natural soil conditions are otherwise unsuited to Parsnips.

It is recognised by capable judges that the flavour of Parsnips is improved by the action of frost; therefore, the crop, as a whole, need not be lifted until required for the table. It is, however, well to have a few roots lifted in reserve, in case frost makes the soil too hard for lifting. With regard to varieties Jersey Marrow, Student and Hollow Crown are reliable sorts. *Geo. F. Copley, N.D.H.*

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents].

Aucuba japonica variegata.—Apropos of the discussion on Aucubas, I may relate an interesting story of 1870, told to me by the late Mr. Walter Povey, for many years salesman at Coombe Wood Nursery. When the male plant was introduced to Messrs. J. Veitch and Son's Coombe Wood Nursery Mr. Povey, then a small boy in the nursery, was sent with a small brush and a little of the Aucuba pollen to pollenate the flowers of a large bush of Aucuba japonica growing on the lawn of a gentleman's house at Kingston Hill. The next spring that gentleman sent for young Povey, who thought he was in for a scolding; instead the gentleman took him by the hand, gave him a sovereign and showed him his old variegated Laurel covered with red berries from top to bottom. I should imagine the first male plant had green foliage. Since then there have been quantities of the plants raised from seeds, and there are now both variegated and green forms of both sexes, some with long leaves, some short, some strong-growing and others dwarf. I have always found male and female plants to be distinct, one producing pollen and the other berries. *Alfred Astley, Ottershaw Nurseries, Chertsey.*

——Having noticed the discussion that has taken place between Mr. H. Copley and Mr. Comber on the fruiting of Aucuba japonica, I may observe that our plants of Aucuba japonica variegata are fruiting very freely, and I send a few sprays for the Editors' inspection. These I picked at random, as I had no idea there were so many berries on the plants until a few days ago, when we were cutting evergreen for decoration. *W. Leith, Clyne Castle Gardens, Swansea.*

Daphne Laureola.—I was very surprised to see in *The Gardeners' Chronicle* that my specimens of Daphne Laureola lost their fragrance *en route* to your office. All six pieces were fragrant when packed. All my bushes are scenting the air round them at whatever time I go, and I have noticed people stopping in our drive as if wondering where the sweetness came from, and then go across to the bushes and put their heads down to smell the flowers. Since sending the specimens I gathered others; I brought them into a warm sitting room where they retained their fragrance for a full week. I notice, however, that the cut stem emits a somewhat disagreeable smell which counteracts the delicate scent of the blooms until the cut ends are put under water, when, of course, it is not perceived. Perhaps the sooty atmosphere in and around London neutralises the scent but I should fancy your Ealing correspondent's bush was hardly fully out, as this is a late year and my plants were not fully out until February 1. *K. M. Hinchliff, Instow.*

Dombeyas.—The recent notes and illustrations of plants of this genus in *The Gardeners Chronicle* have brought to my memory the species of Dombeya which are common in tropical Africa. The most attractive of them all is Dombeya Mukole, a large forest tree, which at certain seasons is covered with its beautiful white blossoms. In places this tree is abundant, and presents a beautiful picture when seen from a hilltop and looking over the forest roof. It provides a very good timber. A shrubby species, very similar in habit to the one figured on page 99 (February 6), is known as D. Dawei. Its flowers are white or a very pale pink. It is of some importance, locally, as a fibre plant. The bark of young growths contains a considerable proportion of very strong fibre. Its general associates are Triumfetta macrophylla and Honckenya ficifolia, both excellent fibre plants. When it is mentioned that thin strips of bark from either of these shrubs are strong enough to use to tie the rafters on a house, a purpose for which they are always used, it will be gathered that they are of considerable local value, and may, some day, be more widely used. A native collecting bark for use in binding will gather from the three plants indiscriminately, all being considered of equal value. *E. Brown, Hillside, Doddington, Sittingbourne, Kent.*

Carnation Baroness de Brinsen.—Having grown this variety of Carnation since it was introduced, I was sorry to read that some growers are discarding it. If the last stopping of the plants is done in May they would find it quite a different plant, producing its glorious flowers all through the winter as freely as any other Perpetual-flowering Carnation. *J. P.*

White Fly.—I have known White Fly as a pest in greenhouses and on plants out-of-doors for some twenty-five years. From my experience tetrachlorethane is not more effective in keeping it in check than vaporising with nicotine, and is much more injurious to plants, in fact, some plants will not withstand it at all. When nicotine vaporising compound could be bought at 12s. 6d. a quart, I used it about three times within ten days or a fortnight: and every morning after fumigating, before the flies had time to rise off the floor, I thoroughly soaked them with water or a soapy insecticide. This treatment kept the houses clean for a long time. I tried the same method with tetrachlorethane and ruined a whole batch of Cucumber plants, practically killed another of Jacobeas, and scorched the leaves of many other plants. It is not always convenient to dip plants, especially when they are in flower, otherwise this is the most effective method of getting rid of the fly and eggs at the same time. Mr. P. Meyer, on page 35, vol. LXXIX, states that he sprays with XL All insecticide, which is also effective if thoroughly performed, but at the first shake the fly will rise and alight on something else and thus escape. In some years all the undersides of the leaves of out-door green crops are literally smothered with the fly, but last year, for no apparent reason, the out door crops were comparatively clear of the pest, compared with what they had been in former years. The White Fly lives and lays its eggs on the common Nettle and wild Cress. *Grigor Roy.*

Romneya Coulteri.—I read with much interest the three letters on the above plant, pages 68 and 69, and from them I deduce the fact that some investigation into the habits, under differing conditions of soil and climate, is still necessary with regard to both R. Coulteri and R. trichocalyx, and I will be most happy to lend any assistance I can, such as the exchange of specimens, either foliage, flowers or even young plants raised from root cuttings, in due season. The very fact, which comes out prominently in two of these letters, that both species died out with *C. M. B.* (Isle of Wight), while with Mr. George Wyatt, Northernhay, Huntingdon, R. Coulteri became a nuisance, necessitating the tearing up of the foundations of a path to get rid of it, shows the utmost extremes of growths and is exceedingly interesting. Regarding the age of plants referred to by Mr. A. T. Johnson, I can only repeat that our plants are probably twenty to twenty-five years old, and have never produced a single sucker. *A. T. Harrison.*

Slugs and Zinc Rings.—I thank Mr. Arnott for his kind appreciation of my note on the "Use of Zinc Rings for the protection of plants from slugs," also for drawing attention to a point which I missed: *i.e.*, the manner of joining the ends of the zinc together to form a perfect ring. If the last tongue at each end is allowed to stand upright and the ends of the zinc strips are bent sharply back in opposite directions, these can be interlocked and will form a joint as effective as soldering, and with the distinct advantage that a separation may be effected easily, and the zinc strips stored flat when not in use. We cut our zinc into two standard lengths: for alpines, eighteen inches long, to form a ring about five-and-a-half inches in diameter; and for herbaceous plants, two feet long forming a ring eleven inches in diameter. If larger rings are required, these may be readily formed by clipping two or more of the strips together by means of the interlocking ends. *F. C. Puddle, Bodnant Gardens, Taly-Cafn.*

SOCIETIES.

ROYAL HORTICULTURAL.

February 23.—Spring flowers were responsible for much of the beauty and brightness of the display at the Royal Horticultural Society's Hall on Tuesday last. Daffodils, Crocuses and Tulips attracted general attention, but not less interesting were the alpine plants and early flowering shrubs, while Cinerarias, Cyclamens, Orchids, Carnations and Roses were all well represented.

Orchid Committee.

Present: Mr. C. J. Lucas (in the chair), Mr. Gurney Wilson (Hon. Sec.), Sir George Holford, Mr. R. Brooman White, Mr. A. T. Pitt, Mr. Fred J. Hanbury, Mr. Arthur Dye, Mr. J. E. Shill, Mr. H. G. Alexander, Mr. Charles H. Curtis, Mr. Fred K. Sander, Mr. John C. Cowan, Mr. Sidney W. Flory, Mr. Henry H. Smith, Mr. T. Armstrong and Mr. E. R. Ashton.

First-Class Certificate.

Miltonia Lycaena, Stamperland var. (*M. Princess Margaret* × *M. Lord Lambourne*).—A superb Orchid with flowers of wonderful size and beauty. It differs from the original in being heavily shaded with crimson in place of the rose-purple of the type. Shown by Robt. Paterson, Esq., Stamperland, Cathcart, Glasgow.

Awards of Merit.

Cymbidium Flamingo var. rotundiflorum (*Alexanderi* × *Merlin*).—A very rounded flower of excellent substance. It is scarcely so large as the type, but is of lovely pink colour with chocolate-red markings on the apical portion of the lip. Shown by Sir George Holford (gr. Mr. H. G. Alexander), Westonbirt, Tetbury.

Odontoglossum citrinum var. Prince of Orange (*eximium xanthotes* × *Boadicea*).—This charming hybrid has rounded flowers of medium size and these have a cream-white ground, shading to yellow at the ends of the sepals and petals, the yellow colouring being enhanced by light orange-yellow blotches on each of the segments, including the lip. Shown by Messrs. Charlesworth and Co.

Vuylstekeara Melba (*Vuylstekeara Brewii* × *Odontoglossum Gorizia*).—In this hybrid the flowers are of large size. The sepals and petals are of a rich plum-purple colour, with a reddish overlay or sheen; the wide lip is softer purple, with the red colouring shown in veins and at the base. Shown by Messrs. Charlesworth and Co.

Brasso-Laelio-Cattleya Nigeria (*B.-L.-C. pulcherrima* × *C. Warscewiczii*).—A handsome and large-flowered hybrid with broad petals of a deep purplish-rose colour. The big lip is of similar colour, with purple markings at the fringed apex, and a light orange, brown-based centre. Shown by Messrs. Charlesworth and Co.

Groups.

Messrs. Sanders had a bold exhibit wherein Cymbidiums and Oncidiums were prominent features. The former were represented by C. Pauwelsii, C. Moonlight, C. Moonbeam, C. Erica Sander, C. Louis Sander var. Aurora—a lovely deep rose-coloured form, and a fine specimen of C. Moira, the pale yellowish cross between C. Pauwelsii and C. Tracyanum. Oncidium Cavendishianum was represented by two large plants. Other good things were Phalaenopsis Schilleriana var. Vivid, Bletia hyacinthina, Odontioda Grenadier, Dendrobium macrophyllum, Restrepia striata and Cirrhopetalum picturatum.

In Mr. Harry Dixon's group we noted such interesting plants as Dendrobium Melpomene, Oncidium cheirophorum, Odontoglossum Crawshayanum, Epidendrum polybulbon and Cypripedium Milky Way. Messrs. J. and A. McBean exhibited the beautiful Cattleya Cowaniae alba, C. Eunice alba, Laelio-Cattleya Arcturus, and several Cymbidiums.

A fine display of Orchids from Messrs. Charlesworth and Co. was greatly admired and many of the plants were particularly fine ones. Miltonia Wm. Pitt, carrying six flowers was especially good, and Odontoglossum Tityus with nearly thirty flowers was another attraction. Dendrobium thyrsiflorum, Cymbidium Butterfly, Odontoglossum Zulu, Sophro-Laelio-Cattleya His Majesty, Cattleya Dionysius, Brasso-Laelio-Cattleya Joan, and several hybrid Odontoglossums were other noticeable plants in a very effective exhibit.

Cattleya Enid alba with four big blooms was conspicuously beautiful in Messrs. Cowan and Co.'s group and around this were displayed Brasso-Cattleya British Queen, of which this firm appear to have a perennial supply, Cattleya Linda, C. Octave Doin, Cypripedium microchilum, C. J. M. Black, and the handsome C. Hassellii St. Mary's var. with deep rose dorsal sepal.

Messrs. Stuart Low and Co. made a comparatively small contribution of Orchids but their exhibit included many pleasing examples, notably Sophro-Laelia Psyche, Dendrobium Chessingtonense var. J. M. Black, Laelio-Cattleya Arcturus with four brilliant blooms, the large-flowered Cymbidium Lady Colman, the finely formed Laelio-Cattleya General Maude, Low's var., Brasso-Cattleya Maroniae, B.-C. Leemaniae, and Odontoglossum scintillans, carrying its seven flowers just as freshly as a fortnight previously.

Messrs. Black and Flory had a bright display and Cypripediums were their leading feature. Of these a few of the best were C. Robert Paterson, of fine colour and size; C. Odin, C. Warrior, C. Golden Sunset and C. Golden Wren. We also noted good examples of Odontiodas and Cattleyas.

Floral Committee.

Present: Section A.—Mr. H. B. May (in the Chair), Mr. J. F. McLeod, Mr. Arthur Turner, Mr. H. J. Jones, Mrs. E. M. Wightman, Mrs. Helen Lindsay Smith, Lady Beatrix Stanley, Mr. M. Fenwick, Mr. E. R. Janes, Mr. J. M. Bridgeford, Mr. M. C. Allwood, Mr. Donald Allan, Mr. F. Streeter, Mr. W. H. Page, Mr. D. Ingamells, Mr. A. Vasey, Mr. J. T. West, Mr. D. B. Crane, Mr. Wm. Howe, Mr. W. B. Gingell, Mr. Jas. B. Riding, Mr. H. R. Darlington, and Mr. Chas. E. Pearson.

Section B.—Mr. Chas. T. Musgrave, (in the Chair), Mr. W. J. Bean, Mr. James Hudson, Mr. G. Reuthe, Mr. Geo. Harrow, Mr. Reginald Cory, Mr. C. Williams, Mr. L. R. Russell, Mr. E. H. Wilding, Mr. G. Yeld, Mr. F. G. Preston, Mr. T. Hay, Mr. Clarence Elliott, Mr. E. A. Bowles, and Sir William Lawrence.

First-Class Certificate.

Crocus Sieberi versicolor major.—A handsome form of the well-known spring-flowering Crocus. The flowers are larger than those of the type. The outer segments are heavily flushed with chocolate except for a narrow, feathered bar of white near the tips. The pure white interior of the flower is relieved by a glowing orange shade at the base. The leaves are short and exceptionally narrow. Shown by E. A. Bowles, Esq., Myddelton House, Waltham Cross.

Awards of Merit.

Cyrtanthus O'Brienii.—This elegant South African bulbous plant was introduced in 1894 and is generally considered to be intermediate between C. angustifolius and C. Macowanii. It bears an umbel of eight or more tubular flowers on slender, erect stems about a foot in height. The flowers, which are two inches long, are of rosy-salmon colour. The small, fresh, green, linear leaves appear at the same time as the flower scapes. Shown by Sir William Lawrence, Bt., Burford Lodge, Dorking.

Primula Allionii alba.—This is an uncommon variety of the mauve-coloured species which is found in the mountains north of Mentone. A compact, almost tufted little plant, with spathulate foliage nearly simulating that of a vigorous Arabis, was shown, and it had four solitary, short-stemmed flowers of almost paper whiteness. These blooms were about three-quarters-of-an-inch across and all were pin-eyed. Shown by Mr. Clarence Elliott.

Rhododendron Nobleanum album, Gill's variety.—A handsome truss made up of large, pure white flowers which have just a touch of pale lemon colouring towards the base of the lower segments. The leaves are relatively small and narrow. Shown by Messrs. R. Gill and Son.

Saxifraga Riverslea.—A crusted Saxifrage of fairly vigorous habit and bearing plenty of long-stemmed purple flowers, usually in pairs. Shown by Messrs. M. Prichard and Sons.

Viburnum fragrans candidissimum.—This is an erect-growing miniature, deciduous variety which has small compact trusses of milk white, sweetly scented flowers. Shown by Sir William Lawrence, Bt.

Groups.

A magnificent group of greenhouse Cyclamens was arranged with conspicuous skill and taste by Messrs. Sutton and Sons on a considerable space against the end of the hall When viewed from the Orchid annexe the colour effect of the many mounds of plants in distinct shades of colour was vividly arresting. The various mounds of plants were set in a cool and effective groundwork of dwarf Ferns and moss. The many plants were shown under their colour names and illustrated a splendid strain as well as the highest degree of cultural skill.

On a table space there was a decorative collection of greenhouse Cyclamens from the Napsbury Mental Institution (gr. Mr. W J. Jennings), St. Albans. This good strain of valuable plants is the result of selection continued for a number of years at Napsbury by Mr. Jennings.

Good collections of Carnations were staged by Mr. C. Engelmann, Messrs. Allwood Bros. and Messrs. Stuart Low and Co. The last named included such good varieties as Violet Mond, Philip Sassoon, White Pearl, and Lady Inverforth. Adjoining the Carnations they had well-flowered bushes of Mimosas (Acacias). Edward Allwood, Laddie, Supreme and Mary Allwood were prominent varieties shown by Messrs. Allwood Bros., while Mr. Engelmann set up handsome vases of Topsy, Tarzan, Laddie and Benora with many other useful varieties.

Exceptionally well-flowered sprays of yellow Banksian and of Fortune's Yellow Roses were artistically displayed by Mr. George Prince who also showed goodly vases of Madame Butterfly and other varieties. Mr. Elisha J. Hicks included beautiful vases of Coral Cluster, Climbing Lady Hillingdon, Mrs. Herbert Stevens and Chas. E. Shea in a valuable group of Roses.

An excellent collection of large flowered Cinerarias was arranged by Messrs. Dobbie and Co. These were splendidly grown plants of a first-rate strain which produces large blooms of beautiful colours.

A graceful group of forced shrubs was displayed by Messrs. L. R. Russell, Ltd., who made good use of well-flowered Wistarias, Pyruses, Azalea mollis, A. indica varieties, and also showed large-flowered Hippeastrums. Various Conifers, suitable for the rock garden, Ericas and other shrubs were shown by Messrs. R. Wallace and Co.

An interesting collection of Rhododendrons exhibited by Messrs. R. Gill and Son included R. argentea, R. ciliicalyx, R. lutescens and brilliant blooms of R. Cornubia. They also showed a large number of flowers of their vigorous strain of St. Brigid Anemones. In his customary group of uncommon plants Mr. G Reuthe showed sprays and plants of several rare Conifers; Andromeda japonica, various Rhododendrons, and an interesting collection of alpines.

In a boldly-arranged sandstone rock garden Messrs. Wm. Cutbush and Son displayed many Azaleas, chiefly of the Mollis type, Pyrus floribunda, and other spring-flowering shrubs, while on the lower levels they planted Iris reticulata, Crocuses, Scillas, and other appropriate subjects. A neat rock garden built by Mr. F. G. Wood provided fitting places for various alpines, including Saxifrages, Primulas, and Muscari, with a few Daffodils. Primulas, Scillas, Saxifrages and Crocuses in pots were shown by Messrs. J. Cheal and Sons.

The graceful yellow flowers of Erythronium americanum were prominent in the well-arranged exhibit of Messrs. WATERER, SONS AND CRISP, who also showed Narcissus minimus, Iris stylosa, I. sind-pers, I. lilacina, and a few Rhododendrons. Messrs. SKELTON AND KIRBY staged Forsythias, Ericas, and Saxifragas. A large collection of Caen Anemones of good bright colours and a few Daffodils were set up by Mr. J. W. BARR.

The Rev. H. A. MEYER, Watton-at-Stowe, again contributed a large number of flowers of Iris stylosa and I. Cantab, with a background of Viburnum fragrans. Various rock garden plants and Conifers were shown by Messrs. SHEPPARDS, LTD., while Mr. GAVIN JONES staged Saxifrages and other alpines. Saxifraga oppositifolia splendens, S. Faldonside, and other good varieties, with Irises and Conifers, were well arranged by Mr. CLARENCE ELLIOTT. Mr. H. HEMSLEY staged well-flowered specimens of Cornus Mas, Grevillea rosmarinifolia, and alpines. Soldanella alpina, S. Sanderi, Saxifraga Irvingii, S. Burseriana sulphurea, S. B. speciosa, and S. kewensis were included in their exhibit by Messrs. R. TUCKER AND SONS.

An admirable collection of alpines in pots and pans was exhibited by C. G. KIRCH, Esq. (gr. Mr. J. Wall), Edenhall, Beckenham. Amongst the many good plants there were excellent examples of Saxifraga Grisebachii Wisley var. × Frederici-Augusti, S. Faldonside, S. Arco-Valley, S. Jenkinsii, S. Russell V. Prichard, S. Buseriana sulphurea, S. Riverslea and S. oppositifolia splendens. Messrs. M. PRICHARD AND SONS displayed in a neat rockery various Saxifrages, Anemone fulgens var., Primula capitata and Ericas. Messrs. W. H. ROGERS AND SON included Soldanellas, Primulas, Saxifragas and sprays of Grevillea sulphurea, with other spring-flowering plants. The Misses HOPKINS had an attractive little rockery with appropriate plants.

About a dozen lovely, soft-pink coloured flowers of Paeonia Moutan, rising above Lily of the Valley set in moss, were shown by H. J. TALBOT, Esq. (gr. Mr. E. Pinnock), Swakeleys, Ickenham, Uxbridge. Mr. J. J. KETTLE had a collection of large flowered Violets of delightful fragrance.

Just inside the entrance Messrs. JAS. CARTER AND CO. had a most delightful spring garden. In fresh green grass of enviable evenness and freedom from weeds they planted artistic sweeps of purple and striped and white Crocuses which spread from the level lawn up the slope amongst the Ericas and dwarf Conifers which made a fitting background to this wholly satisfying and artistic exhibit.

Narcissus and Tulip Committee.

Present: Mr. E. A. Bowles (in the chair), Mrs. Brodie, Miss E. Willmott, Mr. G. W. Leak, Mr. C. C. Titchmarsh, Mr. Chas. H. Curtis, Mr. C. W. Needham, Mr. Jan de Graaff, Mr. Alfred W. White, Mr. Geo. Churcher, Mr. J. W. Jones, Mr. P. R. Barr, Mr. Herbert Smith, Mr. F. Herbert Chapman and Mr. Reginald Cory.

AWARD OF MERIT.

Narcissus Cheerfulness.—A Poetaz variety, and quite distinct, inasmuch as it is a double sport from the popular Elvira. The flowers are of good size and rounded form, and borne in fair-sized clusters. The perianth is creamy white and the centre, composed of small petaloid stamens, is cream-coloured with a surrounding yellow, but broken, corona. We believe this variety originated as a sport with Messrs. Van der Schoot. Shown by Mr. J. W. BARR, Wimborne.

GROUPS.

A considerable space was filled by Messrs. R. H. BATH, LTD., with an imposing exhibit of spring bulbs growing in pans and bowls of fibre. The principal kinds used were Hyacinths, Tulips, Narcissus, Crocuses and Fritillaria Meleagris. The plants were all well grown and the general effect was excellent.

Messrs. BARR AND SONS staged a number of blooms of Narcissus. The very best were of the Trumpet and Barrii sections shown under their seedling numbers. But they also staged beautiful vases of Spring Glory, bicolor Trumpet; February Gold, rich yellow Trumpet; Maximus, yellow Trumpet; with Croesus and Village Beauty with vividly-coloured coronas. Adjoining the Narcissi Messrs. BARR AND SONS had a charming collection of spring-flowering shrubs, with Irises, Lily-of-the-Valley, Anemones and Saxifrages.

Fruit and Vegetable Committee,

Present: Mr. J. Cheal (in the chair), Mr. W. Poupart, Mr. P. C. M. Veitch, Mr. Geo. F. Tinley, Mr. W. Lobjoit, Mr. A. Bullock, Mr. A. E. Newby, Mr. W. F. Giles, Mr. E. Harris, Mr. E. Neal, Mr. G. Woodward, Mr. A. Metcalfe, Mr. E. Beckett, Mr. J. Wilson, Mr. W. H. Divers, and Mr John Basham.

Messrs. GEORGE BUNYARD AND CO., LTD., showed a collection of 126 varieties of Apples, all in excellent condition and representative of most of the best sorts in season. The fruits were all splendid samples of their kind, the more notable being Crawley Reinette, Ontario, High Green Blenheim, Histon Favourite, Brownlees' Russet, Ballinora, Encore, Smart's Prince Arthur, Gabalva, Cornish Aromatic, Belle de Boskoop, May Queen, Blue Pearmain, Easter Orange, Lord Burghley, Sir John Thorneycroft, Allen's Everlasting, Lord Hindlip and Norman's Pippin.

Messrs. SUTTON AND SONS showed a collection of twenty-five seedling Potatos, nearly all second-earlies of their famous "Ben" strain. Each dish was accompanied by a plant to show the distinct habit of the haulm. The varieties exhibited were tried at Ormskirk and declared to be immune to wart disease. It was recommended that the Council be asked to send a letter of appreciation to Messrs. Sutton and Sons for their work in Potato breeding over so many years.

ROYAL CALEDONIAN.

THE first monthly meeting of this Society for the current session was held at 5, St. Andrew Square, Edinburgh, on the 2nd inst. Mr. W. J. Thomson, the newly-elected President was in the chair, and there was a good attendance.

The President took as the subject of his address "The Prevention of Waste," more especially in relation to horticulture. After a general survey of the immense waste which goes on in wild nature, and in many of the industries and other ways, he said that the waste of valuable human food through the depredations of insects and fungi was incalculable, and that if the time and money spent on its prevention could be eliminated the value of our crops would be very much enhanced in value. But until there was better organisation of our teaching machinery, and the practical gardener received more recognition as a factor in the situation, more or less wasteful methods would continue. There was also much need for concerted action in dealing with many of the pests, such as big bud of the Black Currant, without which it was hopeless to bring them under control.

The exhibits were:—Berberis hyemalis, from Mr. MARQUIS, Inveresk Gate, Musselburgh, and Primula Coral Pink from Mr. D. ARMSTRONG, The Drum, Gilmerton. Both exhibits were awarded cultural certificates.

GUILDFORD CHRYSANTHEMUM.

THE annual meeting of this Society was held at Guildford on the 25th ult.; Mr. Westlake, Chairman of the committee, presided.

The secretary, Mr. W. Miles, read the committee's report which claimed that the show held last November was a great success from every point of view. The balance sheet for the year, presented by Mr. W. T. Patrick, J.P., showed a credit balance of £101. Mr. H. Cook, gardener at Stoke Hill House, was presented by Mr. Westlake with a clock as a momento of his success in group showing at the Society's exhibitions in 1924 and 1925—there having been an insufficient number of competitors to enable him to hold the cup presented by Mrs. Hamilton Fellows.

The President, F. F. Smallpeice, Esq., was re-elected; Mr. Westlake was re-appointed chairman of committee; Mr. Patrick, hon. treasurer; Mr. Miles, secretary; and Mr. Olds, auditor.

The Society's show, interrupted during the war, was recommenced four years ago without any funds in hand, but success has followed success, and in the last four years the substantial balance of £101 has been accumulated.

THE ORCHID CLUB.

AT the meeting of the Orchid Club, held on February 12, there was an extensive display of well-flowered Orchids in fine varieties and decorative species.

PREMIER DIPLOMA.

Odontoglossum Mars.—This well-known hybrid, which is remarkable for the magnificence of its solid crimson colouring, large size and excellent shape, was shown with a full spike of fifteen flowers, by Dr. CRAVEN MOORE.

DIPLOMAS OF MERIT.

Cypripedium Athollii (B. Louvain × C. Carola).—A fine flower of excellent habit. The flat, dorsal sepal is of ovate form, three inches across, white, with a median band of crimson; the sepals and lip are well proportioned, and coloured pale green with brown shading. Shown by Sir W. THOM.

C. Elspeth (C. Elise II. × C. Perseus).—A well-displayed flower of very fine shape and proportion. The orbicular dorsal sepal is flat with a large green luna surrounded by a broad white band, a few dark spots being present in the luna. The petals and lip are well-displayed, green, with brown shading. Shown by Dr. CRAVEN MOORE.

CERTIFICATES OF CULTURAL COMMENDATION.

To Mr. WILLIAM A. STEWART for plants of Coelogyne Mooreana and Masdevallia Pourbaixii.

GROUPS.

Dr. CRAVEN MOORE (gr. Mr. W. Gilden), exhibited a very showy group. In the centre was a fine specimen of Dendrobium Lady Colman, and on each side of this were several freely-flowered plants of D. nobile Tyntesfield var. The body of the group was filled with Odontiodas and Odontoglossums among which were well-grown plants of Oda. Freda, Oda. Cora, Odm. Brunhilda, Odm. Pyramus, Odm. Princess Yolande, and several plants of Odm. crispum xanthotes.

Sir WILLIAM THOM (Gr. Mr. R. Williams), staged an effective group in which were several pretty new unnamed seedling Odontoglossums and Cypripediums. This group also included large plants of Cypripedium Hestia vars. Moonbeam and Ruth, and a good variety of C. Lord Wolmer.

A. T. CUSSONS, Esq. (gr. Mr. A. Dalgleish), staged an elegant group of Cymbidiums, including large plants of C. Gottianum, C. Alexanderi rubellum, C. Savageianum, and others; the body of the group was filled in with various Cypripediums.

B. J. BECKTON, Esq. (gr. Mr. W. A. Stewart), exhibited a collection of mixed Orchids, the centrepiece of which consisted of a plant of Coelogyne Mooreana, Westonbirt var., bearing seven spikes of bloom. He also showed the pretty little Helcia sanguinolenta, Gomeza planifolia carrying four long, densely-flowered sprays of light yellow-green blooms with a scarlet dot on the column; the unique-coloured Lycaste lasioglossa, and two dozen plants of Cypripedium Becktoniae, illustrating the remarkable free-flowering habit of this old hybrid.

KINGSTON AND SURBITON CHRYSANTHEMUM.

THE annual meeting of this society was held on Friday, February 5, at Surbiton Assembly Rooms. The President, G. C. Hodgson, Esq., occupied the chair, and there was a good attendance of members and friends. A very encouraging report on the past year's work was read by the Chairman. This stated that the annual exhibition was a great success, about forty per cent. more exhibits being staged, also many very excellent non-competitive groups of plants and fruits. New Challenge Cups had been given by the tradesmen of Kingston and Surbiton, by the late Mrs. Bond, of Croylands, Surbiton, and by M. B. Davie, Esq. The Tradesmen's and Bond Cups will remain the property of the society, the winners receiving N.C.S. Medals. The balance sheet showed upwards of £16 in hand, and five Silver Cups, value £73; this was considered very satisfactory. The president was unanimously re-elected, as was the secretary, Mr. W. H. Divers, V.M.H., and it was decided to hold the next show on Wednesday, November 3, as many small growers find a difficulty in keeping their flowers later than this date.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

Mr. Chas. H. Curtis presided at the monthly meeting of this society, held in the R.H.S. Hall, on February 8. Great pleasure was expressed by the committee when the secretary brought forward twenty-three applications for membership, all of which were accepted; this brought the number of new members for 1926 to thirty-three. Two members withdrew interest from their deposit accounts amounting to £9 17s. 8d., and the sum of £43 4s. 2d. was passed for payment to the nominees of two deceased members. The sick pay for the month on the Private side came to £143 14s. 5d., and on the State side to £152 0s. 2d.; Maternity claims totalled £15. Extra benefit grants were made to nine members, amounting in all to £32 19s. 0d., and six other cases were considered. A draft of the aunual report was submitted and approved for presentation to the annual meeting on March 8, at 7.30 p.m.

GLASGOW AND WEST OF SCOTLAND HORTICULTURAL.

At the monthly meeting of the Glasgow and West of Scotland Horticultural Society, held on Wednesday, the 10th inst, the President, Mr. Charles Young, who occupied the chair, announced the death of their chaplain, the Rev. David Dickie, D.D., Minister of Old Kilpatrick.

Thereafter Mr. R. Prosser, of Messrs. Austin and McAslan's, Cathcart Nurseries, delivered a lecture on "Flowering Shrubs," which he said had been greatly neglected in Scotland, especially in small villa and surburban gardens. In public gardens and parks where gardening was carried on by professional gardeners shrubs received a certain amount of attention, but in the gardens of the amateur, their value and charm were not appreciated as they ought to be. The lecturer emphasised the importance of transplanting and pruning, and he explained the difference in the treatment of evergreen and deciduous varieties.

In the discussion which followed, Mr. Joseph Dobson deplored the lack of originality shown in the gardens attached to corporation housing schemes, while Mr. John Cairns commented on the wonderful results that could be obtained in Glasgow by planting shrubs in a sheltered position. He had seen shrubs as well-grown in the west of Scotland as in Cornwall and Devonshire.

RENFREW HORTCULTURAL.

Lecturing on Border Carnations before the members of the Renfrew Horticultural Society on Thursday, February 18, Mr. David Torrance, Busby, said layers should be planted at the end of September or beginning of October when they would make root quickly and become established before frost sets in. Plants in the open were preferable to those in pots kept in a frame over winter, as they were always stronger and earlier. Carnations were not gross feeders and in emphasizing the evils of over-feeding he recommended weak liquid manure as a safe stimulant. Carnations should be layered, he said, in July, in a compost consisting of pure loam and silver sand, but no leaf-soil, as the latter was a harbour for pests, fungous diseases and weeds. The bursting of the calyx was traced to the work of disbudding, and an excess of heat or moisture, while the keeping of a bud in a perpendicular position enabled it to develop all around and open normally. Mr. Torrance spoke hopefully of the results of experiments with bacterised peat, and described the raising of seedlings as an interesting hobby, despite the glorious uncertainty of the results.

In answer to a large number of questions, Mr. Torrance explained the cause of white spots on scarlet Carnations, affirmed that the last week of February or first week in March was the best time to take early Chrysanthemum cuttings, and detailed the advantages to be obtained by taking Dahlia cuttings as close to the tuber as possible without cutting any part of the surface of the latter.

KIRKCONNEL HORTICULTURAL.

The annual meeting of this Society was held on the 12th inst., when the financial statement showed a loss of £14 18s. 1d., leaving still a balance of £35 5s. 6½d. to the credit of the Society. After discussion, it was resolved to reduce the prizes in the confined classes, and a committee was appointed to revise those in the special ones. As Mr. and Mrs. McMillan, The Knowl, had been of great service to the Society it was agreed to appoint them honorary members. In view of the resignation of the secretary, Mr. J. McCrone, and the treasurer, Mr. J. McCormick, junr., Mr. J. Hardie and Mr. T. Smith were elected joint secretaries, and Mr. James Williamson, treasurer. J. I. McConnel, Esq., Hoddom Castle, was reappointed president. It was resolved to hold the next show on August 21.

Obituary.

James Birrell.—The death took place at Dunblane on Thursday of last week, of Mr. James Birrell who had been gardener at Braco Castle, Perthshire, for nineteen years. Deceased was in his 47th year.

Charles Maron.—With deep regret we have to record the death of M. Charles Maron, of Brunoy, France. M. Maron was in his seventy-fifth year and passed away on February 25. As a young man M. Maron was employed in this country, serving for awhile under Mr. James O'Brien at Messrs. E. G. Henderson and Son's Nursery, and also at Kew. After leaving England he became gardener at Corbeille, where he commenced the work of hybridisation for which he has been famous for many years. Later he took charge of M. Louis Fournier's establishment at Marseilles, and it was here that he raised Laelio-Cattleya Berthe Fournier, L.-C. Andreana, and many other showy Orchids. Rather less than thirty years ago he left Marseilles and established himself at Brunoy, Seine-et-Oise, where he remained until his decease. Some of the earlier Orchid hybrids to flower at Brunoy were Brasso-Cattleya Digbyano-Mendelii, Laelio-Cattleya Ernestii, L.-C. Henry Greenwood, and the fine Cattleya Maroni. M. Maron had a charming personality that endeared him to all his friends, who, in turn, admired him for the skill and patience with which he pursued the business of raising new Orchids by means of hybridisation. He was among the earlier workers in this branch of horticulture, and lived to see wonderful developments, many of which arose from foundations laid by himself.

Walter Povey.—Many who were employed at some period at Messrs. J. Veitch and Sons' Coombe Wood Nursery, Kingston, and many who purchased trees and shrubs at that establishment will have kindly remembrances of Mr. Walter Povey, who for a long number of years was foreman and salesman at Coombe Wood. We have only now received information that this fine old plantsman passed away a few months ago at Ottershaw on the nursery where, as a boy, he commenced his career. He had a wonderful knowledge of trees and shrubs, their cultivation and propagation, and his genial manner and readiness to impart information to young men and to customers won him considerable popularity, esteem and respect. Mr. Povey was about seventy years of age.

Dumitru I. Stefanescu.—We are sorry to learn from our contemporary, the *Revista Horticola*, of the death, on the 18th of January, of Mr. D. I. Stefanescu, a prominent Roumanian horticulturist. Although only forty-three years of age, he had done wonders in the post-war organisation and development of horticulture in his country. He spent four years at the Versailles College of Horticulture, and after his return worked in various capacities under the Roumanian Minister of Agriculture, finally becoming head of the state nurseries and Horticultural Director. He also founded and conducted the *Revista Horticola*, the organ of the Roumanian Horticultural Society, and his final ambition was the foundation of a National College of Horticulture, a task which at the time of his greatly regretted death was practically completed.

TRADE NOTES.

A number of large trees having been prepared for removal near the new city of Delhi, Messrs. William Barron and Son, Ltd., of Barrowash, near Derby, have been instructed to send two of their transplanting machines to the order of His Highness the Maharajah of Bharatpur, Delhi, with instructions for carrying out the work of removal and replanting. Trees weighing from five to forty tons, and up to fifty feet high, have been successfully removed by Barron's transplanting machine in various parts of the world. Amongst the historical trees moved in this country are the Buckland Yew, Dover, mentioned in the Doomesday Book, and the John Knox Yew, at Langbank, on the Clyde, under which tree John Knox administered his first sacrament.

A well-known firm of nurserymen has brought to the notice of the Chamber of Horticulture an experience of interest to the trade in connection with a town-planning scheme. Under these schemes areas are divided into land suitable for (1) dwelling-houses; (2) industrial areas, and (3) open spaces. Upon examination of the plan for the particular district in which this nursery is situated, it was found that the whole of the land occupied by the nursery was scheduled under Section (1), from which it must be presumed that the only development allowable in the future would be the building of dwelling-houses. At the official enquiry it was pointed out how the scheme might prevent extension on the nursery by way of additional glasshouses or nursery buildings. The officials were sympathetic, and stated it was not their wish to prevent any such development, and suggested a special arrangement in order to safeguard this nursery firm. This is being done. Nurserymen and growers whose land may come within the purview of these planning schemes are advised to take an early opportunity of examining their position.

Readers requiring information and advice respecting Patents, Trade Marks or Designs should apply to Messrs. Rayner and Co., Patent Agents, of 5, Chancery Lane, London, who will give free advice to readers mentioning this paper.

NEW HORTICULTURAL INVENTIONS.

THESE particulars of New Patents of interest to readers have been selected from the Official Journal of Patents, and are published by special permission of the Controller of His Majesty's Stationery Office.

LATEST PATENT APPLICATIONS.

1,133.—Cook, H.—Support for garden hose, etc. January 14.

1,259.—Harris, W. G.—Travelling greenhouses. January 15.

814.—Olsen, O. R. and Torkildsen, W.—Manufacture of phosphatic fertilisers. January 11.

545.—Marriott, S.—Garden rollers, etc. January 7.

95.—Lee F.—Frame for growing Peas, etc. January 2.

SPECIFICATIONS PUBLISHED.

245,179.—California Spray Chemical Co.—Insecticides.

245,275.—Dyer, N. S.—Hoeing and thinning implements.

244,705.—Bergerioux, R.—Machines for distributing fertilisers.

244,908.—Lawrence, J. R. H.—Mowing machines and the like.

ABSTRACT PUBLISHED.

A Novel Hoeing Tool. *Patent, No.* 242,909.—A hoe having a pivoted cutting blade has been introduced into this country by Mr. J. Koch, of Jerne, near Esbjerg, Denmark. The tool consists of a yoke-shaped blade, having its ends pivotally connected to arms projecting from a handle so that it is free to move angularly to a limited extent during operation. The ends are bent inwardly above the arms to form stops to limit the movement.

Printed copies of the full Published Specifications may be obtained from the Patent Office, 25, Southampton Buildings, London, W.C.2., at the uniform price of 1/- each.

TRADE MARKS.

This list of Trade Marks of interest to readers has been selected from the Official Trade Marks Journal, and is published by permission of the Controller of His Majesty's Stationery Office.

IRONCRETE.

464,633.—Garden Rollers.—Scoffin and Willmott, Railway Arches, Station Road, Forest Gate, London, E.7. January 30.

SEMSOL.

464,030.—Phosphate Fertilisers.—Richardsons Chemical Manure Co., Ltd., 19, Short Strand, Belfast. December 23, 1925.

464,144.—The word EARLYBIRD, withillustra tion of bird, for a worm-killer and fertiliser.—Joseph Metcalf, Argyle Works, Argyle Street, Accrington. December 23, 1925.

HOOFALIZER.

464,180.—Fertilisers.—Stonehouse Works Co., Spon Lane Mills, Houghton Street, West Bromwich, Staffordshire. December 23, 1925.

GARDENING APPOINTMENTS.

Mr. John W. Dickinson, for the past ten years gardener to the LADY ROSSMORE at the Stud House, Hampton Court, as Gardener to His Grace the DUKE OF NORFOLK, Arundel Castle, Sussex. (Thanks for 2/- for R.G.O.F. Box.—EDS.).

Mr. Stewart Zander has been appointed Superintendent of Coatbridge Public Parks in succession to Mr. WILLIAM ARMSTRONG.

Mr. G. W. Briars, for the past five-and-a-half years gardener to Lt.-Com. CHARLES MEYNELL, R.N., Burcote Brook, Abingdon, and previously general foreman at Orwell Park Gardens, Ipswich, as gardener to A. L. WIGAN, Esq., Forest Park, Windsor. (Thanks for 2/- for R.G.O.F. Box).—EDS.

Mr. John Frank Evans, previously gardener to T. PARTINGTON, Esq., Hayed Eupyn, Colwyn Bay, N. Wales, as gardener to Mrs. LLOYD PRICE, Glyn Abbot, Holywell, Flintshire.

ANSWERS TO CORRESPONDENTS.

BEGONIA GLOIRE DE SCEAUX. *W. A. T.* It is very difficult to state why your Begonia Gloire de Sceaux should drop its flower buds, as your treatment appears to be correct in every respect, and our experience of this Begonia is that it opens its flowers perfectly in the temperatures you mention. Fog will, of course, cause the flower buds to drop, when Gloire de Lorraine is not affected. Are you sure that your plants are not affected with Begonia mite?—generally known as rust. If so, this would cause the buds to drop off. Without knowing all the circumstances we cannot do more than surmise the possible cause of the trouble.

BRITISH PLANTS.—*A. H.* The best complete work on the British wild flowers, with really good illustrations, is the *Handbook of the British Flora*, by Bentham and Hooker. A new edition has recently been issued by Messrs. Lovell Reeve and Co., Henrietta Street, Covent Garden, London, W.C.2. The Flora is 12/-, and the volume of illustrations (drawings), by W. H. Fitch, is 12/-, postage extra.

FLOWERS FOR EASTER.—*L.* You must allow five to six weeks to get Lily-of-the-Valley into flower, and in the absence of bottom heat the longer period will be necessary to get them forward in time. In any case, even when in full flower, they should keep fresh in a cool greenhouse for at least two weeks, although a great deal depends on the prevailing weather. The Liliums will require a longer period ere they flower, much, of course, depending on the weather. You should allow at least two months, therefore, there should be no difficulty in getting your most backward batch into flower for Easter, if you can give them a steady temperature of 60°. Should they become too forward lower the temperature a little; in any case, it is better to be a little too early than too late, as the flowers will keep in good condition for a considerable time..

GARDENER'S ILLNESS AND DISMISSAL.—*H. M.* Without full information on all the facts it is difficult to answer your queries definitely. Whether illness is a good ground for dismissal without notice depends on whether such illness is permanent or only temporary. There has been no decision in the High Court as to what length of notice an under-gardener is entitled to, but at least two County Court judges have decided that he is entitled, like a head gardener, to a month's notice. Such decisions, however, are not binding on other judges, and the matter really turns on the custom of the particular locality. No fixed rule appears to exist as to whether an employee can claim wages during his illness whilst he is in receipt of sick benefits under the National Health Insurance Act, and there have been conflicting decisions on the point, but many employers make up the sick benefit received to the amount of the value of the wages.

GLADIOLUS PRIMULINUS HYBRIDS.—*W. H.* We should not like to hazard an interpretation of the classes mentioned by you. Alice Tiplady and Myra have been taken to represent a new class of "Medio Prims" by one English grower and the American Gladiolus Society is searching for a new name which will clearly designate this new type of flower, "and will give due consideration to our English brothers' views on the same subject." In the meantime where it is desired to exclude the large type the following wording has been used both in America and Canada: "Varieties of primulinus having the distinctive hooded bloom and slender stem as characteristic of the primulinus type or species." Alice Tiplady and Myra were introduced about ten years ago, but Copperhead, introduced last year as a primulinus form, emphasizes the necessity for a distinction being made between such flowers and those of Nydia, La Saviere, Scarletta, Vanessa and Ianthia.

PELARGONIUMS UNHEALTHY.—*W. A. J.* We could discover no sign of fungous disease on the single specimen of Pelargonium received We think, however, the trouble arises from the use of slag on the stages instead of gravel or well-washed cinders. It is quite possible that the slag has given off a poisonous gas (sulphur fumes), and that this is the cause of the trouble.

PINES AT BOURNEMOUTH, ETC.—*Abbey.* The Pine woods of Bournemouth consist principally of the Maritime Pine (Pinus Pinaster, syn. P. maritima) with a few Scotch Pines (Pinus sylvestris). The Somma Cypress, Cupressus sempervirens (horizontal type) is still in existence. Somma is a village about four miles north of Galarate on the railroad from Milan to the Alps. The late Mr. Elwes measured the tree in 1906, giving the dimensions as eighty-five feet high by seventeen feet three inches at five feet from the ground. He considered the legend that the tree was planted in the year of the nativity of Our Lord as most improbable, but suggests that the existing tree is a descendant of an old tree which formerly grew near. The chief sources of supply of wood pulp are Picea excelsa, the Common Spruce, in Norway, Sweden and Finland; Picea alba (syn P. canadensis) and P. nigra in North America, Canada and Newfoundland; Picea sitchensis, P. albertiana and Populus trichocarpa in western North America.

PRUNING LAVENDER.—*M. H. W.* The end of March or early in April is the best time to cut Lavender bushes hard back in spring, but it is doubtful if the plants would produce more than an occasional flower spike here and there on the growths this year. Immediately after the spikes are cut in August is the best time to prune the bushes.

REPAINTING GLASS HOUSES.—*A. H.* Glass-houses have often been repainted inside while the plants or some of them were still there. The usual plan is to move the plants to one end of the house, or partly into a neighbouring house while the other is being painted. Where the paint used was linseed oil, with a moderate amount of turps in it, we have not seen any plant damaged. The end of the house being painted could be given a considerable amount of ventilation during the day, and that would help the paint to dry rapidly and carry off any fumes. When finished, the plants could be taken back to the painted end while the other end is being done. No creosote should be used inside the house, nor any tar on the hot-water pipes. Summer is the best time for repainting inside.

WOOD ASH FOR ALPINES.—*H. L. R.* Wood ash from garden fires forms a good top-dressing for alpine plants. It should, however, be mixed with sharp sand in equal proportions and used with care.

YUCCA WITH SUCKER.—*T. P.* It the sucker is growing quite close to the ground it will probably have developed roots, in which case it would grow quite well if detached and planted separately. If not already rooted you should remove it carefully and insert it in a part of the garden where it would not be likely to receive the full rays of the sun, or you might place it in a pot containing soil of an open texture, when it will root in a greenhouse. With regard to the flowering of Yuccas, this very largely depends on the summer of the previous year. When the weather is very hot for a prolonged time, such as in 1921, the conditions favour the formation of flowering shoots, which accounts for the extraordinary number of Yuccas that bloomed in 1922. Yuccas will flower at intervals for a long number of years.

Early Explorers in Australia.

No romance conceived by the human mind has more of the movement of adventure, the pathos of the unperformed, or the warm glow of achievement than that embodied in the work of the world's explorers. Yet strangely enough the world accepts with nonchalant forgetfulness services for which it might be expected to be for ever grateful. Thus, of that band of adventurers who discovered and explored Australia, all save one or two are unknown to the general body of mankind. Yet the imagination, the courage, enterprise and fortitude of the discoverers and explorers of Australia should be an inspiration to all people of British birth and a sure title to immortal memory. For although the earliest visitants to Australia were surely not British, it was men of their race who occupied effectively this great southern land. Before the English, the Dutch had been there, and before the Dutch almost assuredly, the navigators of Portugal in her great sea days had skirted those shores and perchance set foot thereon; and before them adventurous seamen from Malay, guided by compass which came to them, as it is said, from China, had "discovered Australia." Of these precursors of the British explorers Ida Lee in her work* on the *Early Explorers in Australia* has gathered together much interesting information. Thus, as we learn from her pages, the first specimens to reach Europe (in 1698) from the strange new land were shells of the Nautilus collected by the sea captain, William Vlamingh, who also saw and captured black swans, saw "rats as great as cats which had a kind of bag or purse hanging from the throat downward" and many well-scented trees out of the wood of which "is to be drawn oil smelling as the Rose"—the first record of the Eucalyptus typical of Australia. To Dampier, however, must be given the credit for the first botanical exploration of Australia. He, indeed, preceded Vlamingh, voyaging thither with buccaneers in the *Cygnet*, of London, in 1688, and again visiting and collecting in the *Roebuck* in 1699. With a prescience which is remarkable, in view of the general opinion of the time, which made out New Holland to be a great continent extending over southern Polar regions and uniting with the other southern continents, Dampier declared that though he did not know whether it were island or continent, "it joins neither to Asia, Africa nor America." Thus was given the first blow to the general belief that Terra Australis Incognita—the imaginary antarctic continent—covered the southern part of the eastern and western hemispheres. Although other British seamen had preceded Dampier—the *Tryal* was wrecked there in 1622 and the *London* reached the coast off the Abrothas in 1681—yet the effective exploration of Australia may well be allowed to date from the days of Dampier, when, in 1688, the *Cygnet* being at anchor, natives were seen on the shore and a boat, sent off for water and provisions. Fortunately Dampier, although the sometime companion of buccaneers, was "well acquainted with botany" and it is indeed as curious as fortunate that many other of the early explorers were also and even better acquainted with botany. Dampier's collections of plants—presumably the first Australian plants brought to Europe—are, as the author states, preserved to this day in the Herbarium of the Oxford Botanic Garden. Among the many interesting plants contained in it are Dampier's Glory Pea (Clianthus Dampieri, Cunn.), Casuarina equisetifolia, Melaleuca gibbosa, Solanum orbiculatum, Dammara alba and Trachymene pusilla. And not the least interesting of the numerous illustrations in Ida Lee's volume are the pictures of Australian plants from Dampier's voyages. Not much less than a century had to elapse before Dampier's pioneer work bore fruit; for it was not till 1770 that the Endeavour, a little barque of 370 tons—commanded by the greatest of all modern explorers—carried the White Ensign on what has with justice been called "the most momentous voyage of discovery that to the English nation has ever taken place." The adventurous explorations of the east coast of the continent are, or should be known, to every Briton. To us the fact of capital importance was that a great botanist, Joseph Banks—with Solander as companion—bore Cook company and it was with Lieutenant Cook that Banks and Solarder made their first landing on April 29, 1770, on the east coast at the place now known as Kurnell. There to-day is the inscription "to James Cook and Joseph Banks, the Columbus and Maecenas of their time" recording how "this spot once saw them ardent in the pursuit of knowledge, now to their memory this Tablet is inscribed." Always skirting the coast, and landing here and there, Banks and Solander, were assiduous in collecting, finding almost every plant new and noting with amazement the edgewise set of the Eucalyptus leaves and seeing such profusion that Cook was led to alter the name which he had given to this spot from Stringray to Botany Bay—"the great quantity of plants Mr. Banks and Dr. Solander found in this place occasioned my giving it the name of Botany Bay." Thus, as later history relates, was discovered, and by right of discovery occupied, the narrow strip of land whence spread during two-and-a-half centuries, like wave on wave, ever-reaching further, the explorations which have made known the coasts and hinterland and indeed the very heart of the continent. And thus it was that with a new world a new and unique flora was discovered and made known. Following upon Banks came other botanists, David Nelson in the ill-fated Bounty; Labillardière; Archibald Menzies, surgeon on the Discovery; and then, most distinguished of all, Robert Brown, who went with Captain Flinders on H.M.S. Investigator. The result of Brown's labours are yet to be seen in the collection of his plants in the Natural History Museum at South Kensington. After the successful assault on this continental fortress came a period of consolidation. With the discovery of the splendid harbour, concealed from Cook by the headlands, Sydney became established and inasmuch as it is customary to suppose that the Empire builders builded better than they knew, it is interesting to read the words of Capt. Tench on the arrival of transports and just before the ships sailed past the heads at what is now Sydney Harbour: "to us it was a great and important day and I hope will mark the foundation of an empire." Passing over a period of years during which time many explorers set out to find and at last found a way over the Blue Mountains, which barred the settlement from the hinterland, we come to the advent of another botanist whose but little remembered name deserves honour of all time, Allan Cunningham. As a clerk to Aiton, engaged on the second edition of *Hortus Kewensis*, Cunningham was doubtless inspired with love of travel and botanical collecting by Robert Brown, then librarian to Sir Joseph Banks and concerned with seeing the *Hortus Kewensis* through the press. Cunningham sailed from Plymouth in 1814 by way of Rio de Janeiro and arrived at Sydney in 1816. At first, content to accompany expeditions into the interior, he soon proved himself and became a leader. As he journeyed in the unexplored parts of the continent he planted all kinds of seeds which he had gathered in England, South America and the Cape and no doubt his planting has caused many a surprise to the botanist. Thus it may be that the groups of Agave americana still to be found in places are due to his broadcasting. More beneficent perhaps was his implanting a love of English flowers into the hearts of the early settlers by making a practice of distributing seeds of Primrose, Wallflower and Violet. The curious will find, and will be grateful to Ida Lee for publishing, an epitome of Allan Cunningham's *Journal* for the first two years (1817—18) of his stay in New South Wales and an epitome of his explorations up to the time of his return to England in 1831. Upwards of 400 pages are devoted to the *Journal* and the space is well bestowed, for the *Journal* which is preserved in the Natural History Museum is in its quiet relevance and simple subjectiveness a worthy memorial of a fine character. To the horticulturist interested in plants and their history to turn these pages is to meet a host of plant friends and acquaintances, many of which we owe to Cunningham's introduction. We meet the Eucalyptuses in many varieties, the Waratah, Telopea speciosissima—the carmine-coloured native "Tulip"—loved by the natives for the rich, honeyed juice of its flowers; Phytolaccas, tree Clerodendrons, twelve to eighteen feet high; Olearias, including O. stellulata; Baccharis arguta, many Helichrysums, Grevilleas, Acacia melanoxylon of van Dieman's Land "with its seed attached to the cord by a coloured plicated umbilical cord;" Callitris australis up to seventy feet high; Pancratiums, some new to science; new Tecomas (T. Oxleyi, named after his fellow explorer); Pittosporum, many Acacias, Hakeas—an almost endless band of plants all significant to the botanist and all indicative of the strangeness and uniqueness of the Australian flora. In 1831 Cunningham returned home and to a Kew man home means Kew, so he established himself at Strand-on-the-Green not far from the Gardens. He was offered the post of Colonial Botanist in 1832, but turned the job over to his brother Richard, who was also a man of Kew. But Richard met a sombre fate at the hands of natives soon after he had settled at Port Jackson. Allan consented to take the vacant place and set out again for Australia in 1836. But though a quiet, patient man, his genius lay in the wild and in the exploration of it. He was not happy in the "Government Cabbage Garden," as he called it, and resigned to begin collecting on his own account—"to enter with all his might on a more legitimate occupation." But although full of spirit his health failed. His explorations, save the last, which comes to all, were done. He died at Sydney in 1839 and was buried there where lie so many of Australia's explorers. A marble urn in the Botanic Gardens commemorates him, and yet more appropriate is the commemoration in the names of places he explored, Mount Allan and Mount Cunningham.

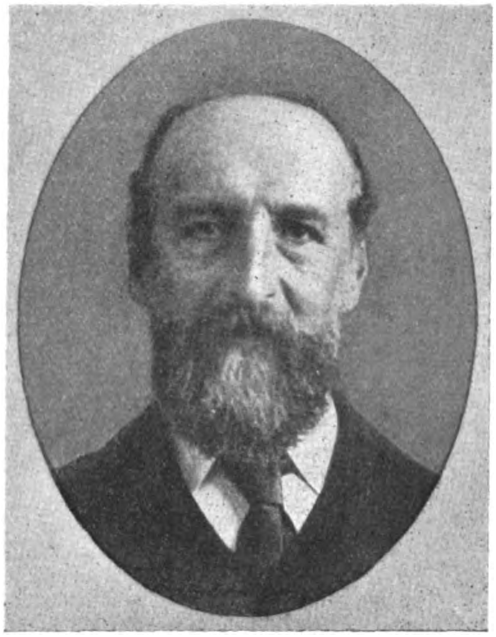
---

* *Early Explorers in Australia.* From the Log Books and Journals, including the Diary, of Allan Cunningham, Botanist. By Ida Lee (Mrs. Charles Bruce Marriott). Methuen and Co., London.

Citrus Fruits and Gourds from La Mortola.—The interesting collection of Oranges, Lemons and Gourds from Mr. Cecil Hanbury's garden at La Mortola that was shown at the Royal Horticultural Society's show on Tuesday, 9th ult., is now on exhibition in House 14c at the Royal Botanic Gardens, Kew.

English Professors Honoured.—The Senators of Aberdeen University have agreed to confer the honorary degree of Doctor of Laws on Francis Wall Oliver, M.A., D.Sc., F.R.S., F.Z.S., Professor of Botany at the University of London, and on Thomas Barlow Wood, C.B.E., M.A., F.R.S., Drapers Professor of Agriculture, Cambridge University, and joint editor of the *Journal of Agricultural Science*.

Dr. B. Daydon Jackson.—The venerable and accomplished general secretary of the Linnean Society will soon be eighty years of age, and on the occasion of his birthday will be presented with his portrait, which is being painted by Mr. Ernest Moore. The cost of the portrait is to be defrayed by private subscription, and those friends of Dr. Jackson who have not contributed to the portrait fund and wish to do so are asked to send without further delay. Sir David Prain is acting as treasurer, and to him, or to Mr. J. Ramsbottom, the Botanical Secretary of the Society, the donations should be sent. We understand that Dr. Daydon Jackson will retire from the position of general secretary on reaching eighty years of age, but will continue in the service of the Linnean Society as Curator of the Linnean Collections, a post that will allow him time and opportunity to write the history of the Society—a task he has long had in view, and for which none is so eminently fitted.



MR. A. ALDERMAN.

Mr. Alfred Alderman.—On the occasion of the twenty-fifth anniversary of the founding of the Croydon Horticultural Mutual Improvement Society, several well-known horticulturists received thanks for the work they had done for the Society. Three were especially singled out for compliments: Mr. John Gregory, the veteran founder of the Society; Mr. Harry Boshier, the hon. secretary; and Mr. Alfred Alderman, chairman of committee. The last-named is an old friend of *The Gardeners' Chronicle*, and one, who, though not now actively engaged in horticultural pursuits, places his wide knowledge and ripe experience at the disposal of the gardeners of the Croydon district, having acted as Chairman of the above Society for twelve years. Mr. A. Alderman commenced his gardening career as a lad, under his father, who was then gardener to J. R. Reeves, Esq., at Woodhayes, Wimbledon. Here he remained for three years as journeyman and then became foreman; for over two years he managed the gardens during the illness which ended in the death of his father. In 1872, Mr. Alderman became foreman under Mr. Henderson, then gardener to Sir Henry Peek, Wimbledon House, a garden famous at the time for its fine collections of plants and general upkeep. When Mr. Henderson resigned, Mr. J. Ollerhead became gardener, with whom Mr. Alderman served as general foreman for two years. His first appointment as gardener was with C. Czarnikow, Esq., at Elm Court, Mitcham, Surrey, where he had ample scope to prove his ability. His employer gave him every encouragement, and Mr. Alderman became a very successful exhibitor, especially of Grapes and Chrysanthemums, for twenty-three years. In 1886, Mr. Czarnikow purchased an estate at Effingham Hill, Dorking; Mr. Alderman went with him and had the pleasure of organising the building of extensive glass-houses and other garden buildings, the lay-out of pleasure grounds and flower borders, and the construction of drives and paths. In these works he gave abundant proof of his skill, to the great satisfaction of his employer, who entertained on a lavish scale. This pleasant association terminated only with the death of Mr. Czarnikow, in April, 1909. At the request of the family, Mr. Alderman managed the place for three years, but owing to the ill-health of his wife, he retired in 1911, and went to live at Croydon, after thirty-five years happy service with a family that still regards him as a personal friend.

Vancouver's Grave.—A number of young Douglas Fir trees, raised at Kew from seeds sent from British Columbia, were planted by Mr. F. A. Pauline, Agent-General for British Columbia, near Captain Vancouver's grave in Petersham Churchyard, on the 27th ult., in memory of the explorer.

Seed-Raising.—Interesting details of the production of seeds for sale were given by Mr. W. F. Giles, of Messrs. Sutton and Sons, at the meeting of the Royal Horticultural Society, on the 23rd ult, the lecturer's remarks being illustrated by a number of beautiful lantern slides. Mr. Giles stated that it is very difficult to obtain pure seeds of any particular variety of the Brassica family unless the respective sorts are grown a considerable distance from other members of the same family, the wind being a potent factor in carrying pollen across the fields from one crop to the other. He stated that whilst the greater number of garden seeds could be grown in this country, there are certain kinds which it is impossible to raise commercially in England, the Cauliflower for example. Most of the Giant Autumn types of this vegetable do best on the shores of the Mediterranean or Adriatic, where considerable areas of the plant are grown for seed-production. Seeds of other types of Cauliflower are grown in northern Europe. With regard to harvesting, seeds, Mr. Giles stated that those of choice flowers for the greenhouse are all carefully picked off by hand and put into little trays or bags to dry. In the case of flowers and vegetables grown out-of-doors, the seed heads are cut and laid on large cloths until they are dry enough to thrash out. Turnip heads for seed are cut, and if the weather is hot and dry the seeds can be thrashed out in the field on large cloths, but in damp weather the seed-heads must be put in stacks until they are dry. Peas are thrashed, graded through machines, and then put on benches for women to pick over by hand.

A New Public Park for London.—By the gift of the site of the Royal Bethlem Hospital to the London County Council by Lord Rothermere, an area of about fifteen acres will be available as a playground and public park in the densely populated borough of Southwark. The gift is in memory of the late Mrs. Harmsworth, mother of Lord Rothermere and the late Viscount Northcliffe, and the new park will be known as the Mary Harmsworth Park. The estate was purchased by Lord Rothermere for £155,000. The building will probably be demolished so that the whole of the site will be available as an open space. At the weekly meeting of the London County Council on the 2nd inst, Lord Monk Bretton stated that the Bethlem Hospital Bill had already passed the House of Lords, and was awaiting second reading in the House of Commons, and owing to the munificence of Lord Rothermere it would be possible, subject to the necessary legislation embodying the agreement entered into by the donor, for the fine open space to be dedicated to the public. It was proposed that the land should be vested in the Council, with rights of management, as a public open space, subject to certain reservations made by the donor, and amendments would be moved to give effect to those proposals. It was hoped that the Council would obtain possession in three years from the date on which the Bill received the Royal Assent.

The Paeony in America.—Mr. James Kelway has kindly sent us a communication received from Mr. A. M. Brand, of Minnesota, president of the American Paeony Society, and from it we make the following extracts:—"It is very strange that the Paeony is not made so much of with you as it is with us and our Canadian friends. From what I have heard and read the English climate must be ideal for Paeonies, and your results should be better than ours, especially as we have much hot, dry and windy weather when our plants are in flower. In the northern two-thirds of the United States and in the southern half of Canada, wherever flowers can be grown, there is no flower that can compare with the Paeony in popularity. We grow beautiful Roses, indeed, we grow all the flowers of the temperate zone, but no flower is thought so much of or so eagerly sought after as the Paeony; it is the pre-eminent flower. The Kelway Paeonies occupy a very high position with us, and no collection is considered complete until it contains such varieties as Kelway's Glorious, James Kelway, Baroness Schröder, Phyllis Kelway and Lady Alexander Duff. This wide appreciation of the Paeony in America has been brought about by the untiring efforts of the American Paeony Society, which has a national scope through the many local societies throughout the country; by the many fine exhibitions of Paeonies; and also by the extensive advertising campaign carried on by the large Paeony growers during the selling season. I wonder you have no Paeony society. Paeony lovers, both in the U.S.A. and Canada, would be intensely interested in anything you could write concerning the history and development of Paeonies, and we should be glad to have the opportunity of publishing such information in the *Bulletin* of the American Paeony Society."

Arsenic in Apples.—A reassuring report in regard to the presence of arsenic in Apples has been issued by Mr. Scott Dodd, City Analyst, Edinburgh. Eight samples were tested, and the results showed that the Canadian varieties, Winesap, Spitzbergen and Rome Beauty, were practically free of the poisonous substance, while minute quantities found in the United States fruits were as follow:—Spitzbergen (White Diamond brand), from Hood River, Oregon, .0072 grains per pound; Rome Beauty, from Buckaroo, Oregon, .0015; Winesap (Snow Kist brand), from Yakima Valley, Washington, .0046; Newtown Pippin, from Sunny Brook Orchards, Oregon, .0103; Newtown Pippin (Blue Goose brand), from Skookum, Wenatchee, .0034. Practically no arsenic was found in the edible portions inside or in the cores, and it was calculated that it would be necessary for one individual to consume nearly two pounds of Apples per day, and to eat every particle—skins, ends and cores—before he would take even one minimum medical dose. In his comments Mr. Dodd stated that mere mention of arsenic suggests to the popular mind poisoning and death, but it was necessary to remember that the poisonous effects of arsenic are limited and that it possesses valuable medicinal and therapeutic properties as well. As a medicine, arsenic is a valuable general tonic, and in small doses acts as a stimulant to the nervous system.

Warter Priory.—Lady Nunburnholme is offering for sale her beautiful home and estate at Warter Priory. Warter Priory is one of the noted gardens of the country, and for many years, especially when in charge of Mr. F. Jordan, these were maintained in splendid condition. The mansion, built on the lines of a French chateau, is surrounded by delightful gardens, and set in a well-wooded estate extending to above ten thousand acres.

The Egyptian Onion Crop.—The acreage planted with Onions this year in Egypt is smaller than in 1925; it is estimated that the 1926 crop will probably not exceed 2,000,000 bags (of 50 kilos), compared with 2,707,000 bags last year. As the majority of the Onion fields were irrigated from two or three weeks later than last year the crop will be about twenty days late, and important consignments are not expected at Alexandria before the middle of March. The crop promises to be good and sound.

Town Botany in Winter.—"Trees and Shrubs" formed the subject of the third of the series of popular lectures delivered by Professor J. Montagu Drummond at Glasgow University on Saturday last. By way of introduction he pointed out that many of the characteristics of trees and shrubs were connected with the fact that such woody plants are perennials of the most pronounced type. The woody plants of cold climates, however, showed many features clearly related to the question of hibernation. The risk which plants ran in winter was not so much that of exposure to cold as that of drying up owing to insufficient absorption of water through the roots, a process which was greatly retarded when the soil was cold, whereas transpiration went on quite actively during winter, especially in windy weather. The most obvious proof of this was the fact that most of our native trees and shrubs were deciduous and cast their leaves—the chief organs of transpiration—in winter. Various arrangements for the protection of shoots and buds during winter were described with the aid of living specimens and lantern slides. The case of evergreen plants was also considered, and the woody plants of the tropics, especially those of a pronounced dry-season area, which display protective features, such as leaf-fall, bud protection, etc., as do our own trees in winter time.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Market Gardening Round London.*—In the Strawberry season, market gardeners provide themselves with thousands of pottles, called quarts. These are formed of white Fir, or laths split up very thinly. The length of the London pottle is eleven inches. The inside diameter at the bottom is an inch, but it gradually enlarges until it is three and a half inches wide at the top, which is finished with a handle rising about four inches above the rim. This pottle properly filled with fruit ought to weigh from twelve to fourteen ounces. For the first early Strawberries, what are called pint pottles are used. These are the same size at the bottom as those just mentioned; but they are only seven inches long, and not quite three inches in diameter at the top, finishing with a handle two inches high. They hold, when filled, about from four to six ounces of fruit. "Punnets" are made of the same material as the pottles. They hold half lb., one lb., two lbs., and upwards, according to the purposes for which they are wanted. Considerable skill is exercised in what is termed, "Topping up a pottle," so as to give to its top the form of a cone. The first row of fruit sits partly on the rim, and exhibits its best broad side half way round the pottle. The next row occupies the bosom of the last, and so on to the top. The other side of the pottle is then "put up" in the same way, and when well done, the fruit is not easily displaced, the pottles are then sent off to market in light spring vans, which hold two tiers of light white wicker baskets; the latter contain thirty-six pottles, but in the case of the best fruit these baskets are divided by first putting in a layer of one lb. punnets, and then a division, filling up with punnets. The supply for the shops is conveyed to them by Welsh or Irish women, who carry them on their heads; these women being paid for every journey they make, earn a good deal of money at this occupation, in which they often walk forty-eight miles a day, *i.e.*, three times, say, from Isleworth, and three times back. This is, however, hard work, which I hope to see performed by the cheap steamboats which now ply so plentifully up and down the Thames. *James Cuthill, Camberwell, The Gardeners' Chronicle, March* 8, 1851.

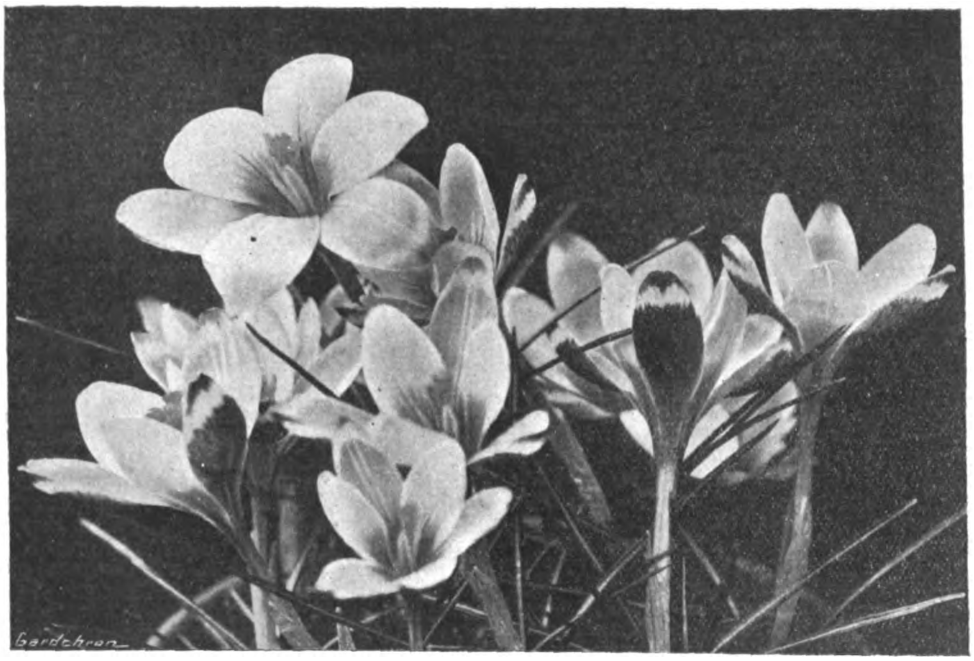


FIG. 78.—CROCUS SIEBERI VERSICOLOR MAJOR.

R.H.S. First-Class Certificate, February 23. Flowers white, with orange base and chocolate markings on the outer segments, Shown by E. A. Bowles, Esq. (see p. 161.)

Trial of Aquilegias at Wisley.—The Royal Horticultural Society will carry out a trial of Aquilegias in its gardens at Wisley during the next two seasons. A packet of seed of each variety to be tried should reach The Director, R.H.S. Gardens, Wisley, Ripley, Surrey, on or before March 27, 1926.

New Allotments at Twickenham.—The Twickenham District Council has purchased for £225 per acre, sufficient land adjoining the northern boundary of the Rugby Football Union Ground, in Whitton Road, Twickenham, to provide fifty-two allotments of ten poles each and two smaller plots. It was decided to name them the Queen's Bridge Allotments.

Appointments for the Ensuing Week.—Sunday, March 7; Wakefield and North of England Tulip Society's meeting. Monday, March 8: United Horticultural Benefit and Provident Society's annual meeting. Tuesday, March 9: Royal Horticultural Society's Committees meet (two days); Jersey Gardeners' Society's meeting. Wednesday, March 10: Glasgow and West of Scotland Society's lecture; Wimbledon Gardeners' Society's meeting; Crowthorne Horticultural Society's lecture; British Mycological Society's Council meeting. Friday, March 12: Royal Horticultural Society of Ireland meets; Orchid Club meeting.

Publication Received.—*Plants from Seed*, by A. J. Macself. Thornton Butterworth, Ltd., 15, Bedford Street, Strand. Price 6s. net.

The Week's Work.

THE ORCHID HOUSES.

By J. Collier, Gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

Odontoglossum.—The Mexican Odontoglossum citrosmum is starting into new growth, but the plant should still be kept on the dry side, for if water is given too freely at this season it usually fails to flower. Immediately the flower scapes appear in the centre of the new growths, the plant should receive more generous treatment in watering, and be afforded an increase of atmospheric moisture. The flower spikes will make rapid progress, and the pseudo-bulbs that have become somewhat shrivelled will quickly regain their normal state of plumpness. O. grande and O. Insleayi should still be resting in the intermediate or the warmest part of the Odontoglossum house. These plants will require little or no water until growth becomes active. Many Odontoglossums of the crispum and Pescatorei type, together with the numerous hybrids that occupy the cool division are in their most vigorous stages of growth. Their new pseudo-bulbs are forming, and it is necessary that great care should be taken for them to be well-developed and matured.

Re-potting.—The necessary re-potting of the main bulk of these Orchids is usually done during September, but any plants that require a larger pot may, if new roots are pushing from the base of the current growth, be attended to now. The plants will be benefited by a liberal supply of fresh air, which should be admitted through the ventilators on the side of the house most sheltered from the wind.

Damage by Slugs.—Many Orchids are developing their flower spikes, and when of sufficient length the latter should be neatly staked. Search night and mornings for slugs, which are very destructive to the young, succulent flower spikes. Lettuce leaves or damp bran placed among the plants form excellent traps.

Sophronites.—The glowing scarlet Sophronitis grandiflora has been blooming for some time past. The flowers are produced from the partly-developed pseudo-bulbs, and soon after the blooms are removed fresh soil may be afforded the plants, if necessary. Frequent root disturbance is not desirable if the compost is in a sweet condition. When fresh rooting materials are necessary they should be applied so soon as new roots begin to develop from the base of the young shoots. Shallow Orchid pans with wire handles attached for suspending them are the most suitable receptacles, and they should be well-drained, as S. grandiflorum requires only a thin layer of compost, which should consist of Osmunda fibre and Sphagnum-moss. The plants grow best when suspended from the roof rafters of the cool house, and should be afforded sufficient water to maintain the Sphagnum-moss on the surface in a green, healthy condition.

FRUITS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Pot Vines.—These vines will need attention in stopping and tying the young laterals. If space is limited the laterals should be pinched at the first joint beyond the bunch, allowing no more growths to extend than space for their full development permits. Perhaps the two most popular varieties for early cropping are Black Hamburgh and Foster's Seedling. Both these Grapes are very free in starting into growth, and both set their berries well, but it is always advisable to assist fertilisation by artificial means either by using a rabbit's tail or by drawing the hand lightly over the bunches. Tapping the wires on which the vines are trained two or three times daily will also help to disperse the pollen. So soon as it is noted that the berries are formed they should be thinned lightly and thinned again after a week or ten days have elapsed; it will then be seen which are the best berries to retain. Weak stimulants may be given the roots on frequent occasions, and nothing is better than liquid manure made from farmyard dung. At a later date a concentrated fertiliser may be used. After the berries are thinned the minimum temperature should not fall below 60°, with a rise of 10° or more on bright days. Fresh air is most beneficial to the vines, and it should be admitted whenever the outside conditions are favourable.

Pot Figs.—Fig trees in pots that were started into growth early need attention in stopping and disbudding the shoots. Trees grown in pots should be stopped at the fifth or sixth leaf, and the work should be done gradually so as not to check the development of the early fruits. The growths should be fully exposed to sunlight and air, which may necessitate thinning them. The Fig, when in active growth should not lack moisture at the roots, and frequent applications of weak liquid manure are very beneficial to growth. Maintain a minimum temperature of 60°, with a rise of 10° or more by day.

Late Vines.—If not already done, the late vinery should be washed down and the walls lime-washed, as advised for the early vinery. When this work is completed the house may be closed, and at this stage a little fire-heat may be used until the buds commence to burst; care is needed not to overheat the pipes or the growth will be weak. A night temperature of 50° will suffice, with a rise of 10° or more during the day.

PLANTS UNDER GLASS.

By John Coutts, Assistant Curator, Royal Botanic Gardens, Kew.

Achimenes.—These plants are useful for furnishing the cool greenhouse during the summer and should now be started into growth. Place the rhizomes in shallow seed boxes, and cover them with leaf-soil and sand. They will soon start into growth in a moist atmosphere and a temperature of 60°. When they have made about two inches of growth they should be arranged in pots or pans, placing the rhizomes from three inches to five inches apart, the distance varying according to the variety; the strong-growing longiflorum varieties require plenty of room. If pots are used they should be well drained, as Achimenes are not deep-rooting plants, and on the whole pans are best suited to their cultivation. Some of the more slender-growing varieties are excellent for filling hanging baskets, A. coccinea being especially useful for this purpose. Although Achimenes are best grown in a temperature of 55° to 60° in their younger stages, they should be accustomed to cooler conditions gradually, so that by the time they have reached the flowering stage they may be transferred to an ordinary greenhouse. Achimenes grow well in a light, rich compost, with free drainage. The shoots should be supported neatly as they require it with suitable stakes. The plants are very subject to attacks of Begonia mite and white fly, both of which pests must be guarded against.

Erythrina Crista-galli.—This handsome plant is very useful for conservatory decoration, and where large plants have been stored dry for the winter they should now be placed in a greenhouse and given a thorough soaking at the roots. If it is desired to increase the stock, cuttings may be secured when the young growths are three to four inches in length. Insert the cuttings singly in small pots; they will root readily in a close case furnished with slight bottom heat. A stock may also be raised by means of seed. With young stock, care must be taken to not dry the plants off too much for a year or two during the winter; not until they have made a good woody rootstock is it safe to dry them off for the winter. This plant should be grown in perfectly cool conditions and be given copious supplies of water at the roots during the growing season.

Begonia Gloire de Lorraine.—This popular Begonia and its several forms should be propagated from cuttings so soon as suitable shoots are available. Early-rooted plants intended to be grown as large specimens should be potted as they require it; the variety Mrs. Petersen is rather slow-growing, and where large plants are required it should be grown on for a second year. It is a good plan to insert cuttings of this variety during November.

THE KITCHEN GARDEN.

By F. Streeter, late Gardener to Major Albert Pam, Wormley Bury, Broxbourne.

Cauliflowers.—Two sowings of Cauliflower seeds will be necessary this month, allowing an interval of a fortnight between each sowing. All the Year Round, Early Giant and Autumn Giant are excellent varieties for present sowing. Prepare sufficient sound boxes and fill them with soil of an open texture. Cover the seeds with finely-sifted burnt earth, place the seed boxes in a cold frame and admit plenty of fresh air. The earlier seedlings are ready for pricking out into cold frames near the glass or in boxes. Give sufficient water to keep the soil moist, stir the surface and dust it with soot. Grow the autumn-sown plants in frames as hardy as possible.

Onions.—The moment the ground can be got into proper condition sow Onions in the open. Rake the surface evenly and dust the land liberally with dry wood-ash and soot. Draw very shallow drills, one foot apart, and sow the seeds thinly, just covering them with soil. Rake the surface neatly. Leave an alley between every ten rows for convenient working, and label each variety, stating the date of sowing. Number the rows, and record where the seed was obtained. This bed should be a feature of the kitchen garden throughout the summer.

Peas.—The early varieties sown in boxes and thoroughly hardened are ready for planting out on a warm border, the soil of which was prepared during the winter. Allow plenty of space between the rows; at least one foot more than the height of the variety given in the catalogues. I find it an excellent plan to plant four rows of early Potatos between rows of Peas. Transplant the Peas very carefully, stake them as the planting proceeds and cover them with netting. Place Spruce boughs on either side of the rows to protect the plants from cold winds. Make weekly sowings of Peas to maintain a succession. Select the varieties for the various sections, and give preference to marrowfat sorts.

Lettuces.—The seedlings of the early sowings are ready for pricking off. Admit air daily to those growing on hot-beds, and damp over the plants before closing the frames early in the afternoon. These plants mature very early. Make frequent sowings to meet the demands of the establishment, and vary the varieties, both of Cabbage and Cos types.

Radishes.—Where Radishes are in constant demand small quantities of seeds should be sown in frames once a fortnight. Just cover the seeds and keep the frames close. Radishes are usually ready for pulling in twenty-one to twenty-eight days from the date of sowing.

HARDY FRUIT GARDEN.

By W. Auton, Gardener to Viscount Elveden, Pyrford Court, Woking, Surrey.

Grafting.—The top-grafting of old Apple and Pear trees is a convenient and quick way of changing the crop of any tree which is giving worthless or unsatisfactory fruits. The actual time chosen will depend a good deal on locality and the nature of the soil, and the operation may be carried out any time during the next few weeks. The point to watch is that the stock should be in a active state, and immediately this is evident, the grafts, which have been heeled in under a north wall and which still show no signs of swelling their buds, should be inserted. This factor of the buds of the scion remaining dormant till the last moment is an important one, hence, when stock-activity is evident the operation should be completed. Trees intended for grafting will have been headed back some time ago, but a fresh, clean cut should be made for the reception of the graft. The methods of grafting are numerous, but the success of all methods depends on the principle of the perfect contact of the inner barks of stock and scion. For old stocks crown-grafting is probably the most satisfactory method owing to the difference in size of the stock and scion, but when the stocks are of medium or small size, whip or splice grafting is suitable. Favourable weather should be chosen for the operation so that the work may be carried out expeditiously. Having prepared the stock, select clean, healthy shoots bearing two or three buds, for the grafts, cut them as required, bring the two freshly cut surfaces together, bind them with raffia and encase the seat of union with a fairly thick covering to ensure exclusion of air. Grafting wax may be used, but well-prepared clay, with which a little chopped moss may be mixed is equally serviceable. This should be well moistened as the ball is built around the graft, and to prevent cracking it is a good plan to encircle the ball with moss, which may be kept moist by spraying during periods of dry weather

Protecting Fruit Blossoms.—The growth of vegetation generally has been surprisingly rapid during the past ten days, and where fruit trees on walls have not already been protected this should be done early during the period of flowering. Whatever type of material is used for this purpose it should be fastened securely so that it cannot be blown about in windstorms, or much damage may ensue to trees and buds. Anything heavier than netting should be removed every morning, while if netting is used it should be hung free of the trees so that one can pass behind it for pollenating the blossoms. The branches of Spruce and other evergreens are frequently used for the protection of fruit blossoms, but if laid directly on to the walls they are a source of danger to the trees and often result in the loss of many buds. Such material makes very useful protective screens, however, if tied to roughly-constructed wood trellises provided with arms to keep them at a short distance from the wall. These may easily be moved in the mornings and evenings, and except where canvas or tiffany blinds are fixed they make the most efficient form of protection that can be employed. Apricots, Peaches, and Nectarines are the first fruits to open their flowers, and should receive first attention; when these fruits have set the protective material may be used for Pears and Plums on walls.

THE FLOWER GARDEN.

By F. C. PUDDLE, Gardener to LORD ABERCONWAY, Bodnant, Taly-Cafn, North Wales.

Primula rosea.—This early-flowering Primula has commenced its season's growth and is sending up its flower spikes. The roots, which always grow near the surface, usually become exposed during the course of the winter, and they will be benefited by a top-dressing of leaf-soil or peat. The general top-dressing of the rock-garden, however, will be better delayed until the end of the present month, for it is a mistake to do this work too early, as the majority of alpines resent wet soil about their collars during the winter.

Dahlias.—If it is found necessary to increase the stock of any varieties of Dahlias, the tubers may be started into growth now in a moderately warm house. When the young growths have made two joints they should be taken off as cuttings with a small heel, and inserted in small pots containing equal parts of loam, leaf-soil and sand. If the cuttings are placed in a close frame they will form roots readily. It will be found the better plan to pot the roots separately rather than box several varieties together, as the danger of mixing the sorts is thus obviated. After the required number of cuttings has been taken, the old plants may be removed to cooler conditions and grown on without further check. If space in a late Peach house or other cool house is available, those tubers which are not required for propagation purposes may be potted in readiness for starting. This work may be done by the flower garden staff during wet weather. Large Chrysanthemum pots may be used as they will be available in time for the final potting of the Chrysanthemums. No water should be applied until the plants show signs of growth; they may then be encouraged to make steady and sturdy growth, which will be so advanced by planting time that the plants will be almost at the flowering stage. The length of the flowering season of Dahlias is governed by autumn frosts, and it naturally follows that the earlier the plants can be had in flower the longer will be their period of beauty.

Roses and Climbers.—The pruning and training of Roses and other plants on walls may now be proceeded with, and where these have been attended to regularly, the work is soon accomplished, but where they are overgrown or have been neglected it is a tedious process, and a great deal of cutting out must be done to reduce them to a satisfactory condition. A mixed collection calls for almost constant supervision, as the different kinds and varieties should not all be treated alike. Clematis Jackmanii and its varieties should be pruned to a bud that is starting into growth, and, as a rule, the greater part of last year's growth removed, but Clematis montana, C. Armandii, and others which flower early in the season should not be pruned until their flowering season is over, when any necessary thinning and shortening of the shoots should be attended to. Ceanothus Gloire de Versailles should be pruned hard to provide a bountiful display of flowers in autumn, but the pruning of the evergreen members of Ceanothus, which include C. dentatus and C. rigidus, should be deferred, as their season of flowering is spring and early summer, and pruning now would mean spoiling the display.

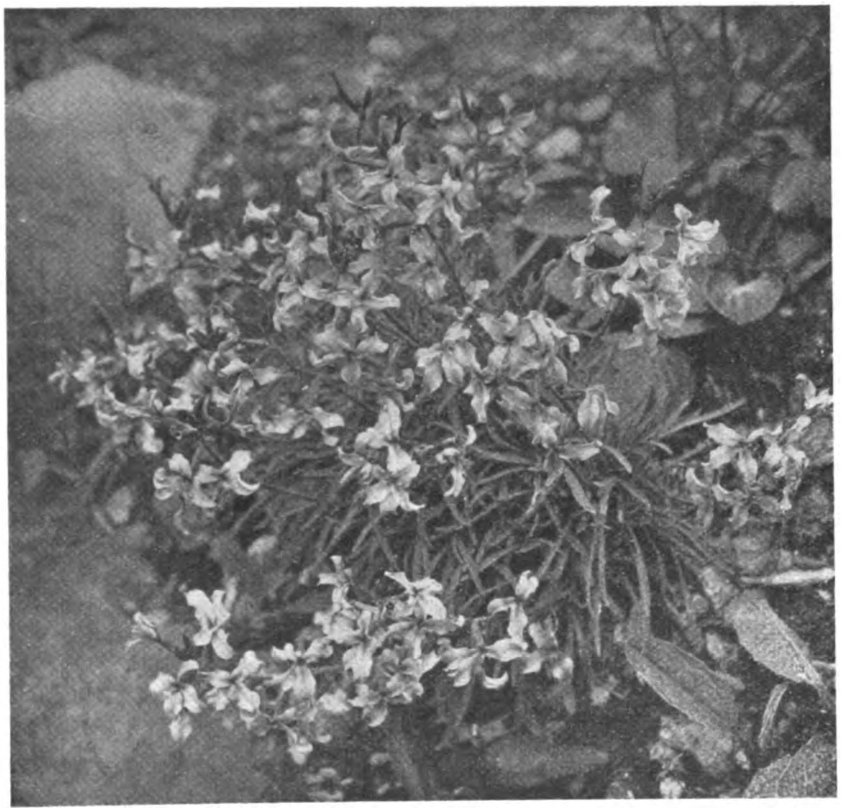

FIG. 79.—MATTHIOLA VALESIACA.

(see p. 170.)

FOR NORTHERN GARDENERS.

By A. T HARRISON, Gardener to the MARQUIS OF AILSA, Culzean Castle, Maybole, Ayrshire.

Sowing of Vegetable Seeds.—Take every opportunity, when the ground is dry, to sow seeds of the various members of the Brassica family in order to have plants ready for setting in their permanent quarters by the end of May or early June. The ground should be well stirred, afterwards consolidated by treading, and made level before drawing the seed lines, which should be twelve inches apart and about one inch deep. Do not sow too thickly, as good, sturdy plants are not obtained in that way; it is better to sow an extra line or two of each variety than to overcrowd the seedlings. When all are sown and the surface made smooth with a rake, it is sometimes necessary to protect the seed-bed from birds. To ward off these and other enemies, I find that a good dusting of lime is very effective, repeating the application frequently during showery weather. Other vegetable seeds which should be sown now include Leeks, Onions, Parsnips, early Carrots, Lettuces, Spinach and successional sowings of Peas and Beans.

Cucumbers and Melons.—Where full crops of Cucumbers and Melons are required from July onwards, seeds should now be sown, and where a temperature of 60° to 70° may be maintained in the house they may be grown to perfection. The seeds should be sown singly in small pots filled with sandy loam, which should be thoroughly moistened before the seeds are inserted. Plunge the seed-pots to their rims in sand or cocoanut fibre in a propagating case. Any subsequent watering before the seeds germinate should be with a view to keeping the plunging materials moist; guard against an excess of moisture in the pots. So soon as the young plants are above the soil they should be placed in a light position secure from cold draughts. When large enough they should be transferred to larger pots, using good loam mixed with sand and wood ash to render it porous.

FLORISTS' FLOWERS.

THE BORDER CARNATION IN SPRING.

THOSE who grow border Carnations in the open and not under glass may be divided into two classes: those who leave their plants out in the open the whole year; and those who pot the layers in the autumn, keep them in a cold greenhouse or frame during the winter, and plant them out in their flowering quarters in the second half of March or early in April. The former method is probably the better of the two, for the border Carnation is a true perennial, and will withstand successfully the vagaries of an English winter.

Autumn-planted layers have the advantage that they are well established when the spring arrives, thus their development when growth begins continues unchecked until the time of flowering. Against this the advocate of protection in winter claims that casualties from waterlogged soil, cats and other causes are prevented if the plants are kept in pots until the spring. I always treat border Carnations as hardy subjects and plant my layers in the autumn in the open in the places where they are to flower. It is an easy matter to pot a few extra plants to fill any vacancies which may arise through failures, and I think that this method is to be preferred.

Those who have kept their plants in pots during the winter will soon be transplanting them into the open, and it is the subject of their treatment after that operation has taken place that I propose chiefly to discuss.

No matter whether the plants have been in the open all the winter or are ready to be put out, a liberal dusting of lime will be most beneficial to the soil, and its use cannot be too strongly advocated, for border Carnations are lovers of lime, and will eagerly assimilate it.

When all the stock is planted the Dutch hoe should be used diligently on all favourable occasions. Apart from keeping down weeds hoeing, by loosening and turning over the surface soil, aerates the ground and assists in keeping it sweet and friable.

As the plants progress, the need for tying and staking will become apparent and should not be delayed. Light canes or sticks, three feet long, form very satisfactory supports and, if it is possible to put these in position in the spring, so much the better, for there is then less chance of damaging the young roots of the growing plant. About the middle of May, it will be essential for the plants to have some support, and, if the grower is content to adhere to the old method of tying with raffia, he will find the operation laborious. There is, however, no need to use raffia, rings made from galvanised wire being preferable and more quickly manipulated. These rings may be purchased from the horticultural sundriesmen at about three shillings and sixpence per thousand, or the energetic gardener can make them at home by winding thin, galvanised wire around a broom handle and then, after the resulting spiral has been removed, cutting through each successive turn with a pair of pliers. It is the work of a moment to open a ring, slip it around the plant and stick and close it again.

As the plants progress, little attention will be needed beyond the use of the Dutch hoe to stir the soil, especially after rain, and tying either with raffia or using rings as this becomes necessary. When the flowering season is near at hand the grower will be well advised if he gives his plants an occasional watering with a weak stimulant made from old soot, as this will be found very beneficial to the plants and at the same time, enhance the colours of the flowers. Peruvian guano has been recommended for this purpose, but I know of nothing better than an application of the liquid obtained from a tub in which a bag of old soot has been suspended for a week or two. A weekly application will suffice, and the liquid should be applied after being well diluted with water.

When the flower buds have formed, all the small ones which cluster at the base of the crown bud and large side buds should be rubbed out, and it is also advisable to remove some of the side buds, too, if flowers of the highest quality are required. Much depends upon the variety and also upon the inclination of the grower, but it is a mistake to leave a number of small buds when by their removal the quality of the remaining flowers is greatly enhanced. However, as I have stated, disbudding is a matter for the grower to decide for himself, and, after his first year's experience, he will know what suits him best.

With regard to layering, I would emphasize the foolishness of many growers who wait until the middle or end of July before commencing to layer their plants, simply because they have been told that it is best to commence then. The plants should be layered directly the side shoots are sufficiently developed, even if the plants have not flowered. By this means plenty of time will be available to do the work, which is usually crowded into a few short weeks, and, in addition, the plants will be well advanced in the late summer, and have ample opportunity of developing strong roots by the time winter arrives. *Angus Bennett.*

ALPINE GARDEN.

MATTHIOLA VALESIACA.

THE members of the Stock family are mainly lowland plants, growing in warm and dry localities. Matthiola valesiaca (Fig. 79) is an exception, for it is found wild in the Valais, from which it takes its specific name, growing high up on the rocks of the Simplon, and about Binn amongst other places.

It is closely related to the better-known M. varia which is found in various parts of southern Europe. Some authorities class it as a variety of the latter species, from some of the forms of which it is difficult to distinguish. I have also had plants under the name of M. pedemontana, in which I fail to find any difference from M. valesiaca, indeed, it was illustrated in *Gard. Chron.*, April 23, 1921, under the former name.

M. valesiaca is a perennial with a somewhat woody rootstock: This is of spreading habit, making its way underground along crevices and amongst loose stones. From these are produced tufts of obtuse, linear leaves, covered with glandular and stellate hairs, giving it a hoary appearance. The stems are erect, with a leafy base, and grow from four inches to one foot high, according to soil and situation.

In May and June the reddish-violet or mauve flowers are produced in numerous racemes, making it an attractive plant for the rock garden. It is quite hardy when planted on a sunny ledge or in the crevices between stones and old walls. The drainage should be perfect, as with excess of moisture it damps off in the winter. Seeds are produced freely and cuttings also root readily in the summer, while it may also be propagated by means of root-cuttings in the autumn. *W. I.*

MAZUS PUMILIO.

THIS native of New Zealand and Australia has both the charms of distinctness and of beauty of flowers so that its failure to attain due recognition is surprising. Some state that the plant is a little tender, yet in the greater part of the British Isles, at least, it withstands a more than average winter without injury.

It is of creeping habit, spreading underground. I believe that some losses are caused by growers desiring to restrict its increase, instead of allowing the plant to spread.

The leaves are small, hairy, of a pleasing shade of green, and rarely rise more than one inch above the surface. The flowers which appear in summer, are distinct in form and are of violet colour with a white centre. The plant is easily increased by means of division in spring or immediately after flowering.

The cultivation of M. pumilio calls for little comment. It is said to thrive in ordinary loam, but a better medium may be formed by adding one part of sand and one of leaf-mould to loam. A sunny, somewhat sheltered spot should be chosen, but not too much exposed to the morning sun in early spring. This Mazus is an excellent plant for the rock garden, where, although it needs a dryish, well-drained place, it is all the better for occasional waterings in dry weather. *S. Arnott.*

ACAENA BUCHANANII.

BUCHANAN'S New Zealand Bur has for long been one of my favourite carpeting plants. It covers the ground closely and there are few plants which serve better as a carpet for choice little bulbs than this and other members of the genus Acaena. It cannot boast of brilliancy in its flower heads, being far inferior to A. microphylla in this respect, nor can it well claim supremacy over that species in the point of the colour of its foliage. It has a beauty quite different from A. microphylla but is as charming a plant. The rounded flower-heads are bristly and yellowish, the leaves a delightful grey-green. As a carpe for choice spring or autumn Crocuses or for big Meadow Saffrons such as Colchicum Bornmuelleri or C. speciosum album, it is superb, the delicate cups of the Crocus or the bolder flowers of the autumn Meadow Saffron looking well associated with the foliage of the Acaena, and preserved by its carpeting mass from splashes of soil cast up by the rain. It is not such a deep rooter as to be injurious to the bulbs or corms of the other plants.

Acaena Buchananii may be increased almost indefinitely by division, while seeds are also obtainable. In the course of a few years a plentiful stock may be obtained, and the plant will serve usefully for other purposes than that indicated above. For planting in the crevices of stone paths or steps, or for clothing a bare bank, A. Buchananii is invaluable, while it withstands a good deal of ill-usage, being even employed in some places as a kind of "supplementary door mat!" It will grow in sun or shade and in almost any kind of soil. *S. Arnott.*

BULB GARDEN.

BEDDING HYACINTHS.

WHILE the Hyacinth can hardly equal the Tulip as a bedding plant it has some valuable attributes which make it useful for bedding purposes, not the least of these being its early flowering period and the comparatively long season of display. Somewhat more expensive than Tulips to purchase, they are not so widely grown, but if the right varieties are chosen and attention is given to their cultural needs they provide a display at an early period of the year commensurate with the outlay involved.

There are certain varieties, as all who have had experience in growing Hyacinths in the open know well, that however beautiful they are under glass, are comparatively worthless when planted out, hence the field of choice is much more limited than is the case with Tulips. Nearly all the varieties with flowers of an intermediate shade of colour are washy and ineffective if they are, as is usually the case, exposed to rough weather when in flower, therefore the desirability of selecting those only which have flowers of a decisive hue, such as bright pink, rosy carmine, or deep blue. Yellow varieties, however good they may be under glass, are seldom satisfactory in the open, and produce at the best only a moderate cream, hence in planting schemes where light shades are desirable it is preferable to use pure white sorts.

Hyacinths are very suitable for planting in formal beds in sheltered positions near the dwelling house, as their rich display and earliness in flowering make them peculiarly attractive for such positions. The carpeting of beds filled with early-flowering bulbs is an excellent plan and makes the beds much more interesting during the whole of the winter. It is not, however, so easy to carpet beds filled with Hyacinths as it is those filled with Tulips, as the former have very little bare stem, and such plants as Silene and Myosotis would completely hide the flowers. There are, nevertheless, a few dwarf-growing plants that are eminently adapted to this purpose, and amongst them may be mentioned Sedum glaucum, S. Lydium, Antennaria tomentosa, A. candida and Saxifraga moschata.

The employment of carpeting plants naturally entails some extra labour, but as the Hyacinths are in most instances planted in beds in full view of the windows, and the Hyacinth foliage covers very little of the ground it is essential that the soil should be partially hidden.

The plants mentioned may be increased very easily, and by their use some saving in bulbs may be effected, as wider planting can be practised than would be possible if the soil is left perfectly bare.

When the flowers have passed and it is necessary to prepare the beds for summer bedding, the bulbs may be lifted carefully and planted closely together in a sunny border to finish their growth. The carpeting plants may be broken up and planted in any open position in the reserve garden, with the exception of the Saxifraga, which should be given partial shade. *A. P. C.*

ORCHID NOTES AND GLEANINGS.

ORCHID HYBRIDS.

During 1925 the lists of hybrid Orchids published in *The Gardeners' Chronicle* included some three hundred novelties, a number slightly under the average, but sufficient to prove the great interest taken in this phase of indoor gardening. While the majority of the raisers were well-known Orchidists, both amateur and professional, several new raisers have come forward. The hybridist's object is to produce flowers larger in size, perfect in shape, more beautiful in colour, and in other ways excelling the best features of the species used as parents. The greater number of the showier Orchids have been used as parents, and the operators have cleverly selected the most promising species for primary crosses.

Of Cattleyas nearly three hundred direct crosses with Cattleya Dowiana have been made, and over 130 crosses with its first progeny, C. Hardyana, which enters largely into the whole section of showy, hybrid Cattleyas and Laelio-Cattleyas, most of which, if their history is traced, have C. Hardyana as a prime ancestor. This has played a great part in influencing the size, form and colour of the hybrids, and although the colour of its sepals and petals is seldom reproduced in them, it gives, by judicious crossing, a large number of pure yellow-petalled hybrids, and pure white-petalled forms, either albinos, or with large and richly-coloured labellums. The influence of C. Dowiana illustrates what may result from using a pure species as a parent.

Some thirty-five species of Cypripedium have been crossed and inter-crossed, resulting in nearly three thousand beautiful and distinct hybrids. These Orchids are the chief subjects in some noted amateurs' collections, and when the large size, beauty and wonderful lasting properties of these flowers are considered, they are worthy of inclusion in all collections. C. insigne varieties lead with about 140 direct crosses.

There are still large numbers of species as yet unused as parents, and a revival of Orchid importing is desirable, not only on account of the beauty of many species, but to extend the work of the hybridist. *J. O'B.*

CATTLEYA REMY CHOLLET.

Messrs. Sanders, St. Albans, send a noble flower of their latest novelty in Cattleyas which they consider the best Cattleya they have yet raised. C. Remy Chollet was obtained by crossing C. Monarch (Empress Frederick × Trianae Monarch) and C. Trianae ignea. The result is a large-flowered hybrid, with a C. Trianae base, the C. Dowiana in C. Empress Frederick giving extraordinary width and richness of colour to the lip.

The sepals and petals are silver-white with a delicate blush rose shade. The petals extend eight inches from the point of each and are nearly four inches in width at the broadest part. The tube of the lip is coloured like the petals and much crimped at the margin. The front lobe of the lip is rounded and broadly displayed; it is rich ruby purple with a chrome-yellow disc on a white ground in the centre.

INDOOR PLANTS.

RHODODENDRON LINDLEYI.

Rhododendron Lindleyi is a native of Bhotan, and although first introduced in 1864, is very uncommon in gardens, probably because of its unsatisfactory habit of growth rather than the fact that it requires the shelter of a cool greenhouse. The supplementary illustration shows the beautiful white, wax-like, aromatic flowers, which are carried in terminal umbels, the number of flowers varying from three to six. The corolla tube is usually about three inches long, and the limb three to four inches broad, but the size of the flowers varies considerably according to the health of the plant. The flowering period is usually towards the end of March or during April.

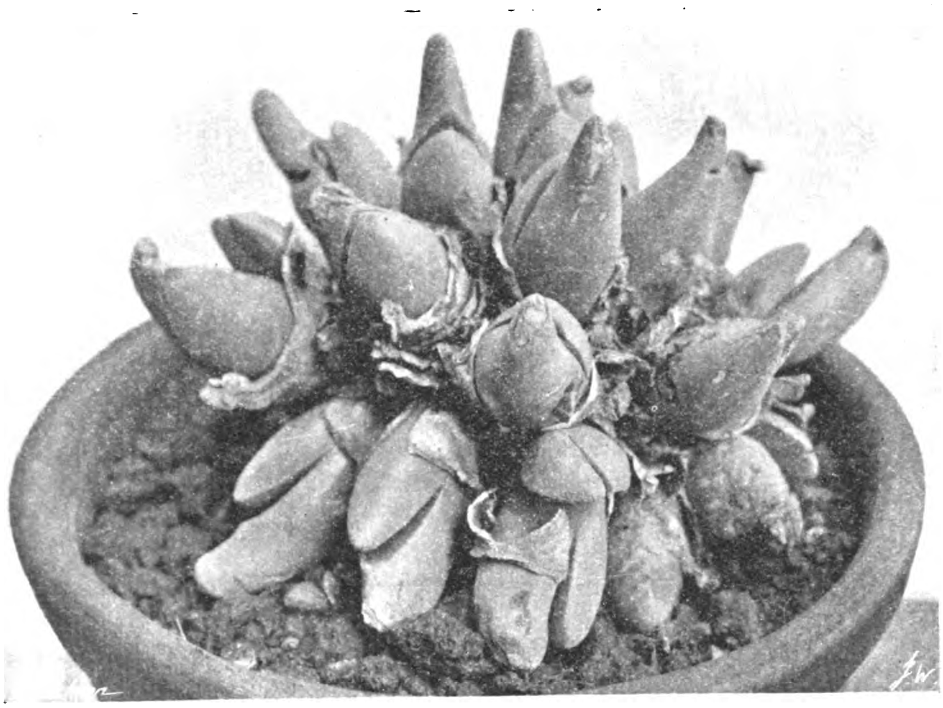

FIG. 80.—GIBBAEUM (MESEMBRYANTHEMUM) GIBBOSUM.
(From a photograph: see p. 172.)

The leaves, which are produced at the end of the straggling shoots, are from three to four inches in length, coriaceous, glaucous on the underside, with small brown dots. This Rhododendron appears to be mid-way between R. Dalhousiae and R. Nuttallii, and, like them, is no doubt semi-epiphytic, which accounts for their more or less unsatisfactory behaviour under cultivation. They succeed best when planted out in a well-drained border, in a compost of light loam, and lumpy, fibrous peat, to which has been added clean, sharp sand and some fairly large pieces of charcoal.

In the Himalayan House at Kew R. Lindleyi grows about four feet high, the bare, straggling shoots being terminated by a few leaves, and flower buds in their season. The illustration represents a plant growing in the Himalayan House at Kew and is reproduced from a photograph by Mr. C. P. Raffill.

CUPRESSUS FUNEBRIS AS A POT PLANT.

As in most other species of Cupressus this plant has two types of leaves, the adult and juvenile foliage. The juvenile plant produces whorls of three or four awl-shaped leaves of a sea-green colour, soft and feathery, contrasting charmingly with the older red-brown stems. Later, as the plant attains age, it assumes the flattened growth and close, scale-like leaves of the mature Cypress, and bears fruits freely; but it is then far less valuable as a decorative plant.

Specimens varying from a few inches to as many feet in height are grown for market, their beauty and lasting qualities rendering them valuable for decoration.

This Conifer is easily propagated from cuttings inserted in sandy soil and placed under a bell-glass in July: failing such convenience a well-drained seven-inch pot, half filled with sand and covered with a sheet of glass, will suffice. Water the soil sufficiently to keep the cuttings in a fresh state. The bell glass may be white-washed on the sunny side, or the pots may be stood on the shady side of a wall. When rooted, the cuttings should be potted singly and established before the advent of winter. The shelter of a cold frame will, in the southern counties, be sufficient, but growth will be more rapid in a greenhouse.

When the pots are well-filled with roots the latter may receive a stimulant, but not so much as to cause excessive growth.

For some reason, perhaps because of its awl-shaped foliage, this Cypress is often sold as a Juniper, and it is not uncommon to find it labelled Juniperus bermudiana, a name belonging to a totally different plant; its common name is the Chinese Weeping Cypress.

In Sussex, and doubtless in several other counties, it will succeed in the open and may, when too large for the greenhouse or conservatory be planted out in a sheltered corner, where it may either be allowed to grow into a small tree or be restricted to a small size by careful pruning. In its native habitat, Central China, this Cypress will attain a height of seventy feet. *J. Comber.*

MESEMBRYANTHEMUM.

(*Continued from p.* 156).

(5.—Gibbaeum, Haw.)

Tufted, succulent perennials, stemless or with prostrate branching stems. Each growth consisting of an ovoid, obovoid, subglobose or obliquely subglobose body, slightly notched or distinctly and equally or unequally lobed at or just below the top, or transversely fissured or more usually of an obliquely ovoid, oblong-ovoid or subcylindric body with a fissure on one side of it resembling a closed or slightly open mouth, formed of two opposite, equal, subequal or very unequal leaves more or less united into a solid body, or the unequal leaves more widely separated and spreading, but still united at the lower part. Flowers pedicellate, bractless, with the ovary usually exserted from the fissure. Calyx 6-lobed down to the top of the ovary. Petals numerous, free. Stamens numerous, erect. Stigmas 6–7, plumose or filiform. Ovary inferior, 6–7 celled; placentas on the outer wall or floor of the cells. Capsule broadly obconic, convex at the top, with 6–7 valves and cells; valves with their expanding keels diverging from near their base and shorter than the valve, but with broad, membranous, obtuse marginal wings produced nearly or quite to the tip of the valve. Cells roofed with flexible membranous cell-wings, without a tubercle at the opening. Seeds numerous in each cell, very small, ovoid, with a nipple at one end.—Haworth, *Revis. Pl. Succ.*, p. 104, and N. E. Brown in *The Gardeners' Chronicle*, 1922, vol. LXXI, p. 129.

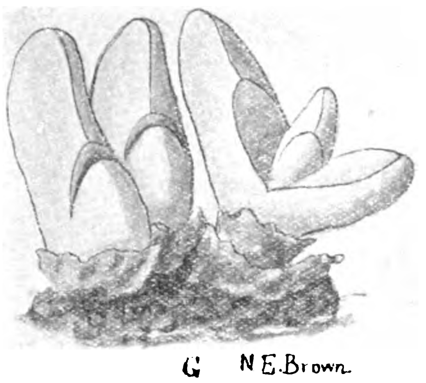

FIG. 81.—GIBBAEUM GIBBOSUM.
(From a drawing.)

Species 11, natives of the Karoo region and apparently chiefly of the Klein (Little) Karoo of South Africa, the type of the genus being G. pubescens, N. E. Br.

The name is derived from the Latin, *gibba*, a hump, in allusion to the prolongation into a hump of the back of the larger of the two leaves of which the body or growth is composed, forming what appears to be the apex of the growth.

This genus is easily distinguished from Mesembryanthemum and all other allied genera except Conophytum by its peculiar vegetative character, and from the former by its stigmas, constantly 6-7-celled ovary, 6-lobed calyx, and the 2-edged pedicels of its less rigid fruit. From Conophytum (for which genus I formerly mistook one species whose flowers I had not seen) the free petals and the presence of cell-wings roofing the cells of the capsule, readily distinguish it.

My former account of this genus was published in *The Gardeners' Chronicle*, 1922, vol. LXXI, pp. 129 and 151, at a time when very little was known of it in Europe, and I had then seen no flowers of any species belonging to it. Since then one species has flowered here at Kew, and I am indebted to Dr. J. Muir for flowers of six other species that he has recently sent to me for examination, from which it would appear that the flowers of all the species of this genus exude a considerable quantity of nectar, which covers the whole surface of the top of the ovary and is also on the stigmas. I have also had more opportunity of studying some of the species under cultivation, the result being that I believe that Haworth's species as described there have not all been correctly understood. G. pubescens as there described by me is undoubtedly the plant Haworth called Mesembryanthemum pubescens. But with reference to his M. gibbosum, M. perviride and M. luteoviride, I am doubtful if these species are correctly understood in Europe. On p. 151 above quoted, I illustrated G. perviride and G. gibbosum. The plant I figured as G. perviride here reproduced (Fig. 81), I had cultivated for many years under that name, which I believe was the name sent with it from South Africa, and as it agreed fairly well with Haworth's description I accepted it as being correct. But the plant figured on the same page as being probably G. gibbosum, here reproduced (Fig. 80), although then so different in appearance and colour, has now developed into a plant identical in every respect with that I figured as G. perviride, and although I have not yet seen flowers of either I feel certain that they both belong to one and the same species. And so far as I can judge from Haworth's description, it is probably G. gibbosum, and therefore his M. perviride and M. luteoviride are still unknown species. I therefore propose to cancel my previous descriptions of these two species and replace them with translations of those given by Haworth. The description of G. gibbosum being correct so far as I can at present make it and taking into account that the figure and description of the growths (not the flower) of G. perviride merely represents the cultivated appearance of G. gibbosum, both figures being here reproduced (Figs. 80 and 81), those descriptions and figures must suffice for the present for all that is at present known to me of G. gibbosum. It is very unfortunate that the localities of numerous species described by Haworth are quite unknown, for had the locality where they were found been stated it would have enabled us with more certainty to identify some of the plants he described that are at present unknown.

Although Haworth's descriptions of these plants are vague, yet from his sectional characters of them as a group there can be no mistake as to the kind of plants he describes, for to the group or genus he assigns the following characters :—" Leaves opposite, an inch long, very stout, united almost to the middle, one abbreviated, gibbous, the other much enlarged at the apex and oblique. Calyx usually 6-fid. Corolla small, rubicund, flowering in winter and spring."

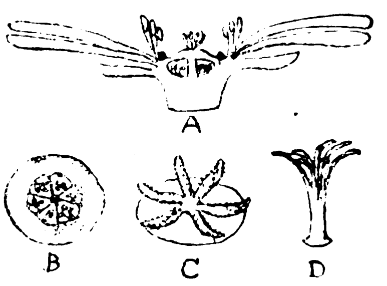

FIG. 82.—FLORAL STRUCTURE OF GIBBAEUM.
A. and B. Section through flower, and transverse section of ovary of Gibbaeum pubescens. C. stigmas of G. Muiri. D. stigmas of G. molle. All enlarged two diameters.

Fig. 82 is a diagram representing the floral structure of this genus, from which it will be noted that the stigmas of the various species vary very considerably in size and character, affording excellent specific distinction. All the figures are drawn to the same scale of being enlarged two diameters, so that it will be seen that the difference in the size of the stigmas is very pronounced. *N. E. Brown.*

(*To be continued*).

HARDY FLOWER BORDER.

DICTAMNUS CAUCASICUS.

Dictamnus caucasicus is one of the most useful plants for the hardy herbaceous border for it is attractive either in foliage or in bloom. A characteristic feature of the plant is that if a lighted match is placed below the inflorescence on a sultry evening in summer, a flash is observed which gives off a very pleasant odour and, strange to state, the ignition does not in any way injure the plant. This Dictamnus is perfectly hardy; it grows from two feet to two-and-a-half feet tall and produces reddish-purple flowers from June to August.

THREE GOOD CENTAUREAS.

Centaurea macrocephala is a fine plant for the middle or back row of the herbaceous border. The plant bears large heads of golden yellow flowers during July and continues in bloom to September. It grows five feet tall and is perfectly hardy. Another showy plant is Centaurea dealbata, a species with bright rose-coloured flowers and growing one-and-a-half feet tall. This Centaurea has showy silvery foliage.

Centaurea ruthenica, a Russian species with pinnate leaves and pale yellow flowers, attains a height of four feet and flowers from July to September. All three species thrive in ordinary garden soil.

PYRETHRUMS.

During the early summer and autumn, the single and double-flowered Pyrethrums contribute much to the beauty of the hardy flower border. Since Pyrethrum roseum, a Caucasian species, was introduced, many improved varieties of single and double types have been raised. Their yield of flowers is most prolific, and as decorative garden plants with the most brilliant of glowing colours and long flower stems they are extremely useful for furnishing cut flowers for house decoration.

Pyrethrums may be planted any time during the early spring or in early autumn, the former being the better time. They grow well in any moderately moist, rich, loamy soil, and in order to obtain the best results well-rotted manure should be incorporated with the soil which should be well-trenched and well-drained. Grow the plants in a sunny position.

When the plants are in flower bud during spells of drought, give the roots copious supplies of water. It is also beneficial to apply a mulching if the situation is a dry one, and, to prevent attacks of slugs, a dressing of coal ashes is desirable.

Pyrethrums are extremely hardy and not affected by sun or rain; they may be left undisturbed for two or three years, provided they receive an annual top-dressing. The elegant Fern-like, deep green foliage makes a most perfect setting to their stout, wiry, flower stems, which grow about two feet tall. The colour of the flowers range from snow-white to delicate pink and rose, through scarlet to the deepest maroon.

Though the natural time of flowering of these Pyrethrums is from May-June onwards, a very creditable display may be had during autumn, if the first flowers are removed when they are over. The varieties are so numerous that it would be invidious to attempt to give a selection; the following are only a few of the best :—Double white: Aphrodite, Argentine, Carl Vogt, White Queen Mary, Mount Blanc and White Astor.

Double blush to rose :—La Vestale, Madame Munier, Madame Patti, Paul Journu and Queen Mary.

Double crimson and scarlet: J. N. Twerdy, Lord Rosebery, Marquis of Bute, Progress, and Beauty of Laeken.

Pericles is a distinct, creamy yellow variety with paler guard petals, while Vance has cream flowers, prettily tipped with pink. The single varieties are much prized for cutting. A few of the freer-blooming sorts are Comet, crimson;

Countess of Leitrim, soft, rosy-peach; Edward VII, soft, rosy carmine; Elsie Gertrude, pink; General French, velvety-crimson; Hamlet, clear rose; Jubilee, crimson; Lady Knaresborough, soft blush; Langport Scarlet, glowing scarlet; May Robinson, clear rose-pink; Pink Pearl, delicate shell-pink; Warrior, carmine-purple; and Snow White, a large-flowered variety. *W. Logan.*

TREES AND SHRUBS.

FORSYTHIA SUSPENSA.

It is many years since this beautiful shrub was more beautiful in this district than it is at the present time. The clear-toned yellow bells impart a touch of brightness to a scene long darkened by winter.

The species is perfectly hardy near the south-western seaboard of South Wales, but it is hardy only in sheltered places in the North of England. Those who require a really decorative shrub should plant Forsythia suspensa in October or November next, subject to the geographical limitations above stated. It appreciates a good, well-drained soil. Those who have established bushes in flower now should prune them so soon as the flowers fade. Weak and badly-placed shoots should be removed first, afterwards cutting out some of the branches that have flowered. This treatment will enable the young growths to develop and ripen satisfactorily. *Geo. F. Copley. N.D.H., Cardiff.*

RHODODENDRON NOTES.

Judging from the number of well-plumped-up flower buds, the present year promises a fine display of Rhododendron bloom. The wet autumn of 1925 resulted in free growth late in the season with a corresponding formation of buds. During the dry spell experienced in June-July last year Rhododendrons suffered severely, and those newly-planted could only be kept alive by watering and mulching. From mid-July, however, they made excellent headway, as if benefiting by the retarding influence of the previous drought.

I find the variety Gill's Triumph is not hardy here (mid-Surrey), although it makes good growth and forms fine buds. Each winter these buds have blackened and dropped, evidently the result of frost.

The variety Cynthia is very susceptible to cold weather and behaves in a most noticeable way as the thermometer drops. The leaves droop to an acute angle and remain so until milder weather returns. The plant does not appear to suffer permanently, however, and blooms well each year. Bagshot Ruby is a great acquisition, its beautiful colour always exciting admiration. It has a dwarf, sturdy habit, and should be planted in the front of other varieties, or in the shrubbery. A pleasing combination is obtained here by planting Bagshot Ruby and Corona interspersed with varieties of Japanese Maples. The beautiful tints of the young Maple leaves blend well with the Rhododendron blooms, and by the time the flowers are over the fully developed Maple foliage has filled out, at the same time, affording welcome shade to the Rhododendrons during hot weather. In winter, again, the Maples are hardly noticeable, having lost their foliage, and the full beauty of the shining leaves of their companions is fully exposed to view.

The woodland R. ponticum is a mass of buds and as we have large clumps of this species, twenty feet high, they should be a glorious sight in spring. Many thousands of seedlings make the intervening ground a green carpet.

A debatable point that has come to my notice recently is, should the buds of newly-planted Rhododendrons be picked off? I have never practised it, nor do I think it advisable for the following reasons:—The plant has already gained the necessary energy to form its flower buds from the previous year's growth. It will bloom before growth is necessary for the ensuing year's buds. The plants are always lifted with a good ball of soil, full of roots, thus they receive no appreciable check to growth. If the dead blooms are picked off immediately after flowering there is plenty of time for the plant to grow and form flower buds for the following year, and lastly, why sacrifice a season's bloom for, at the most, a very slight gain in growth, which is likely to be stunted by a hot summer? I have heard it said that a fruit tree would not be allowed to fruit the first season, and that the same thing applies to Rhododendrons.

There is no analogy. The fruit of an Apple or Pear is draining the tree up to the end of the growing season; moreover, the fruit tree suffers a severe shock at moving and needs a whole season to become re-established. By picking off the dead flowers of Rhododendrons fruiting is prevented.

A number of Rhododendrons planted here in close proximity to large trees have been languishing for years, giving little or no bloom. A heavy mulch of decayed cow manure last winter has worked wonders; the plants are now full of good buds and should make a fine display this year.

I find, although heavy mulchings are necessary on light soils as here, it is unwise to place the dung near the stem, as a form of stem rot results, and we have lost one or two plants in this way. *R. G., Cobham, Surrey.*

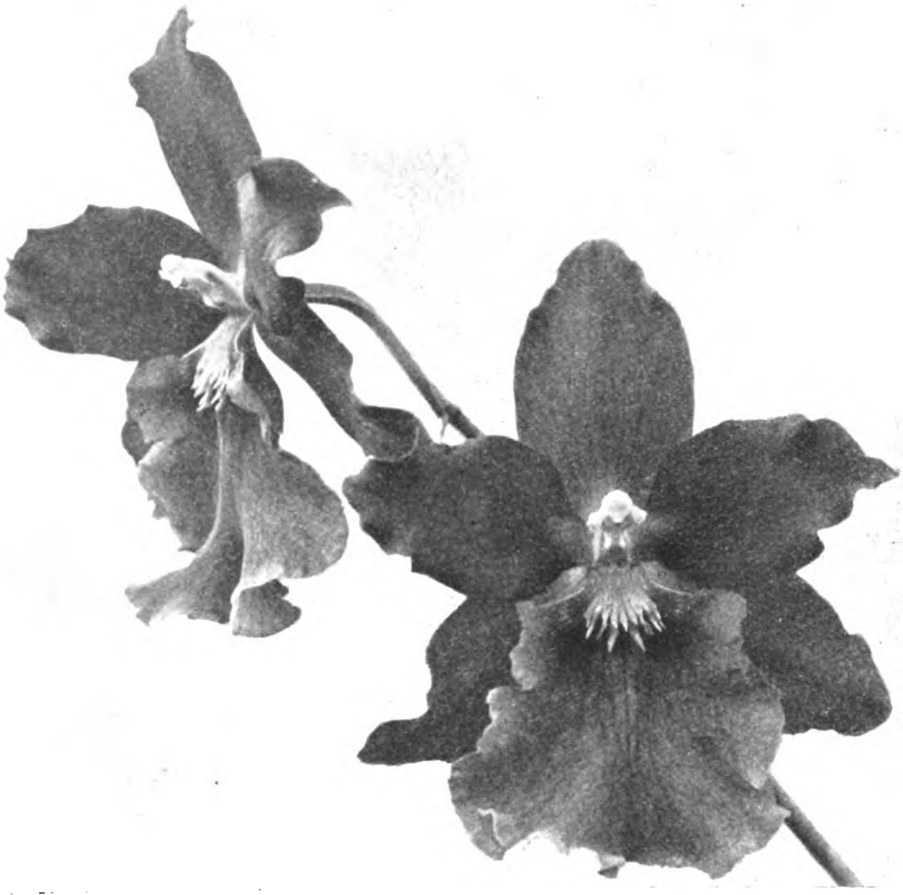

FIG. 83.—VUYLSTEKEARA MELBA.

R.H.S. Award of Merit, February 23. Flowers plum-purple with crimson shading. Shown by Messrs. Charlesworth and Co. (see p. 161).

FRUITING OF RIBES SPECIOSUM.

In his article on Ribes speciosum, *A. T. H.* Ayrshire, states that he has not seen fruits on his plants, and suggests that it rarely fruits in this country. At Bodnant, R. speciosum rarely fails to produce a good crop of its small red Gooseberries, which are of a rather strong flavour.

A. T. H. recommends that pruning should be performed "by the removal of the older wood so soon as the flowers are over." I would suggest that the check which would follow the removal of any quantity of wood at that time would tend to cause the dropping of any fruits which may have set, and this is probably a contributary factor in *A. T. H.'s* failure to secure a crop of fruits. The method of pruning we adopt in these gardens consists in thinning the growths to prevent over-crowding, and this is performed in winter, in common with other Gooseberries. *F. C. Puddle, Bodnant Gardens.*

SYCOPSIS SINENSIS.

This evergreen shrub from China is again producing its curious yellow flowers, and although these are not of a very showy character, the mere fact of the plant flowering during February should be sufficient to warrant its inclusion where a representative collection of shrubs is grown.

The flowers are composed, for the most part, of a large number of yellow stamens, enclosed in a brown, scaly bract, and they last on the plant for a considerable time. The dark green leaves are of a leathery texture, dull, not shining, and closely resemble those of some of the larger-leaved forms of Cotoneasters, particularly C. frigida, being from three to four inches long and sharply pointed. S. sinensis is quite hardy; it is a native of central China up to an altitude of 4,000 feet above sea level, and was introduced in 1901 by Mr. E. H. Wilson. *A. T. H.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed "Gard. Chron.," Rand; or by telephone, to Gerrard, 1543.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

CLASSICAL AND LEGENDARY GARDENS.

III.—THE GARDENS OF ALCINOUS.

EVERY ancient people had its poet, and every poet had a marvellous garden for his theme. The Hebrew had his Paradise, the Persians sang of the Rose and the nightingale, while the Greeks and Romans had their Gardens of Adonis, the Hesperides and Alcinous. These last have been celebrated in the story of the Argonauts, and especially in the *Odyssey*. Alcinous, the grandson of Poseidon, was the host of far-famed Ulysses, and heard from him the story of his wanderings. Like all the other mythical personages of antiquity he and his romance have been worked up in many ways by the exponents of the Solar Myth. Let us first hear the story, and then take the interpretation.

Alcinous, the fabled King of the Phæacians, had a beautiful daughter to whom Pallas appeared in a dream, with instructions to wash the robes of state in the river preparatory to her nuptials. While she and her maids were indulging in pleasant pastime, Ulysses, awakened by their voices, addressed the princess, who gave him relief and informed him how to make himself known to the king and queen of the island. Ulysses went to the capital, and being introduced to Alcinous and Arete the queen, related to them how he had left Calypso and found his way to their domains. In the seventh book of the *Odyssey* the palace and gardens of Alcinous are described:

> " The chief with wonder sees the extended streets,
> The spreading harbours and the riding fleets;
> He next their princes' lofty domes admires,
> In separate islands, crowned with rising spires:
> And deep entrenchments, and high walls of stone,
> That gird the city like a marble zone."

Pallas, who has shown him the way, now leaves him, gazing at the royal gates. The folding doors are encased in plates of gold, the pillars are of silver on a brazen base, these same precious metals being employed in the lintels and "ringlets that command the door," while

> " Two rows of stately dogs, on either hand
> In sculptured gold and labour'd silver stand.
> These Vulcan form'd with art divine, to wait
> Immortal guardians at Alcinous' gate."

Fair thrones adorned the palace, while richly-embroidered carpets, the handiwork of matrons, lay around.

After supplying us with other details relating to the palace, its staff and appointments, the poet proceeds to the description of the spacious garden, consisting of four acres of ground, fenced all round with a green enclosure and protected from storms and inclement weather. Here thriving trees told of the fertility of the soil; here fruits of many kinds were grown, vines were cultivated, and herbs arranged in order, while the whole enclosure was plentifully supplied with water from two graceful fountains. It may be of interest to enquire, a little more in detail, into the nature of the plants which this delightful legendary garden produced.

The first to be mentioned is the Apple. This word, however, has been used in so vague a manner that we have to be on our guard respecting it. The fruit in the Garden of the Hesperides was the Golden Apple—one which is common to many legends. Indeed, as Folkard has pointed out (*Plant Lore, Legends and Lyrics*, p. 223), the Apple is represented as the magical fruit *par excellence* in the popular tales of all countries. It was sacred to Venus, who, like Apollo, is often represented with the fruit in her hand. The Thebans offered Apples at the altar of Hercules. By the ancient Druids, Celts, Saxons, Greeks, Romans, Norsemen, and Germans, one and all, the Apple was held in high esteem. For its names, distribution and native haunts reference may be made to De Candolle's *Origin of Cultivated Plants*, and other similar works. It should, however, be observed that the Quince, whose antiquity in Greece is shown by Pliny, Plutarch and others, is held by some authors to be the fruit which is spoken of as an Apple. In the Gardens of Alcinous " the reddening Apple ripens into gold."

Next in order is the Fig. " Here the blue Fig with luscious juice o'erflows." Many people find this fruit unattractive, and speak of an acquired taste. To me it is one of the most delicious fruits to be found in our gardens. If not indigenous, it has been grown from time immemorial in almost every land. The Greeks, Arabs, Hebrews, Egyptians, Persians and other nations of antiquity, each had their own name for the Fig, which seems to indicate that it was always familiar to them. In Homer we read of a Fig tree which grew near Troy, and in the Hebrew Garden of Eden Adam and Eve are said to have sown Fig leaves together to make themselves aprons.

The Pomegranate is said to have glowed red in this wonderful garden, and this is a fruit which always vies with the Olive, the Fig and the Grape in ancient literature. Thus, to quote as before from Pope's translation:—

> " Here the blue Fig with luscious juice o'er flows,
> With deeper red the full Pomegranate glows;
> The branch here bends beneath the weighty Pear,
> And verdant Olives flourish round the year."

When we remember that the Pear grows wild over the whole of temperate Europe and Western Africa, particularly in Anatolia, to the south of the Caucasus and in the north of Persia, as well as, possibly in Kashmire and China, we shall not hesitate to admit its claim to a place in the palace gardens of Alcinous. But it is, quite naturally, to the vine that greatest prominence is given.

> " Here ordered vines in equal ranks appear,
> With all the united labours of the year;
> Some to unload the fertile branches run,
> Some dry the blackening clusters in the sun,
> Others to tread the liquid harvest join;
> The groaning presses foam with floods of wine.
> Here are the vines in early flower descried,
> Here Grapes discoloured on the sunny side,
> And there in autumn's richest purple dyed."

These lines, written some centuries before the dawn of the Christian era, show a full knowledge of viticulture, whatever may have been the state of knowledge in the days of Alcinous.

What the other plants were which flourished here we do not know, except that:—

> " Beds of all various herbs, for ever green,
> In beauteous order terminate the scene."

In later chapters we shall have occasion to study some of the many herbs which were cultivated in the gardens of antiquity, and we may justly assume that those which gained distinction among the most famous gardens of classical times, on account of their fragrance, medical properties and culinary attractions, were such as Alcinous would grow. We should find the Parsley and probably Portulaca, Cresses, Lettuce and Endive, perhaps the Beet and certain Crucifers, Leeks and Onions, and the fatal Poppy, to mention no others.

Very pleasing is the final touch which is given to the picture, because it not only accords with what we know of the very earliest historical gardens of Egypt, Assyria, Palestine, Greece and Rome, but reminds us how the Hebrew prophets utilised the circumstance as an illustration.

> " Two plenteous fountains the whole prospect crown'd,
> This through the gardens leads its streams around,
> Visits each plant, and waters all the ground;
> While that in pipes beneath the palace flows,
> And thence its current on the town bestows:
> To various use their various streams they bring,
> The people one, and one supplies the king."

Attention has more than once been drawn to the words of Isaiah: " Thou shalt be like a watered garden, and like a spring of water, whose waters fail not," re-echoed by Jeremiah and the Psalmist, as showing how dependent the garden was upon its streams, fountains and springs.

Let me quote at this point a characteristic sentence from Ruskin: " The whole view from Richmond Hill or Windsor Terrace, the gardens of Alcinous with their perpetual summer, or of the Hesperides (if they were flat and not close to the Atlas) golden Apples and all, I would give away in an instant for one mossy granite stone a foot broad, and two leaves of Lady Fern."

And now, in conclusion, we turn to the interpretation as given by one school of mythologists, represented by Sir George Cox. Alcinous was the King of the Phæacians, whose wonderful country is none other than Cloudland. " The Cloud-land in all its magnificence and imperial array is displayed in the great Phaiakian legend of the Odyssey. . . He who has seen in the eastern or western sky as lit up by the rising or setting sun, the cloud-capped towers and gorgeous temples catching the light on their burnished faces, can well feel whence came the surpassing and everlasting glory of the palace of the gardens of Alkinoos. . . Who does not see that in the gardens of this beautiful palace must bloom trees laden always with golden fruits, that here the soft west wind brings new blossoms before the old have ripened, that here fountains send their crystal streams to freshen the meadows which laugh beneath the radiant heaven?" *Mythology of the Asian Nations*, vol. XI., 274 *et seq.*)

Readers will perhaps differ from this learned expositor, and take their interpretation from a later school, or hold a view of their own quite independent of either. *Hilderic Friend.*

PARAFFIN AS A FUNGICIDE.

As a result of recent references in *The Gardeners' Chronicle* to the use of paraffin as a fungicide, I hope the following remarks may be of some interest to readers.

Paraffin or ordinary mineral "burning oil" has been used extensively in the past as a contact wash for controlling sucking insects, but its effectiveness as a fungicide requires further investigation. I know of no cases except those referred to above where the ingredient has been claimed to display actual fungicidal properties.

Paraffin belongs to a series of hydro-carbons known as the "aliphatic" and it is one of the lighter distillates obtained during the distillation of ordinary petroleum: it is also obtained from the distillation of shale. Paraffin

Supplement to The GARDENERS' CHRONICLE

RHODODENDRON LINDLEYI.

wax, lubricating oils and mineral jelly are also members of the same series, differing principally in physical characteristics such as boiling point, specific gravity, etc., some being viscous liquids, and others actually solid.

Paraffin has been extensively used in the United States in an emulsified form, in both commercial and private horticultural practice, but in recent years it has fallen into disfavour owing to damage by scorching having followed its use. The damage has undoubtedly been due to improper emulsification in the first place, and insufficient spreading when applied as a spray, owing to what is known scientifically as a high surface tension.

The higher boiling-point section, known as lubricating oils, are now very largely used in an emulsified form during the dormant period for the destruction of certain hibernating insects and scales. It has been claimed that these oils possess definite ovidical properties in the same way as the new tar oil washes, but I am very doubtful if such is the case.

Paraffin oil, as is well-known, is insoluble in water, but it can be made miscible in water by a process of emulsification, giving a white, milky-like solution in dilution with water. This may be accomplished by a chemical or physical process. The well-known method of dissolving soap in water, adding paraffin, and then thoroughly agitating the mixture by means of a garden syringe, is an example of the latter. An emulsion prepared in this manner produces only a temporary emulsion, causing the oil to separate out on standing and to rise to the surface of the mixture. Herein lies the explanation of damage by paraffin.

The object in emulsification is to break up the oil into fine droplets or globules and to protect them with a material which will prevent them from coalescing again. This may be accomplished by boiling with soap and various other materials. An excellent method for producing such an emulsion is herewith given.

FORMULA.		WORKING FORMULA.
Paraffin oil ...	40·0%	5 galls.
Potash, fish oil, Soft Soap ...	30·0%	30 lbs.
Cresylic or Carbolic Acid ...	6·0%	½ gall.
Naphthalene	2·0%	2 lbs.
Water ...	22·0%	2½ galls.

Place the oil, cresylic acid and soap in a suitable boiling copper, heat until all the soap dissolves, add the water and finally the naphthalene and continue heating until a clear, thin, jelly-like appearance is obtained. The final product may be used at the rate of one pound to two pounds to eight gallons of water, depending on the species of plants to be sprayed, their age, delicateness and vitality. On dilution with water there should be no oily drops on the surface of the spray solution. It should be carefully noted that paraffin emulsions should not be used with water containing much lime or chalk-hardness, otherwise separation of the oil will occur.

The best results will be obtained with such a product as mentioned above by dissolving two pounds or three pounds of ordinary horticultural soft soap (free from free alkali) in eight gallons of water, and then adding the one pound to two pounds of the paraffin jelly. Such a solution will give very excellent spreading and penetration. The value of a paraffin emulsion can be still further enhanced by the addition of a quarter to a half fluid ounce of pure nicotine to every eight gallons to ten gallons of the diluted emulsion. If a supply of rain water is available it is not necessary to use the extra quantity of soap.

Delicate plants that have been treated with paraffin emulsion should be again sprayed with clear water a few hours after the application of the emulsion.

The most effective spray for rust on Chrysanthemums, in my opinion, is ammonium-copper-carbonate solution, used at the rate of one gallon to from eighty to one hundred gallons of water. *Theodore Parker.*

NOTICES OF BOOKS.

The Families of Flowering Plants.*

SOME of us "in the know" have been eagerly looking forward to the appearance of this handbook of the Dicotyledonous Families, and with the result now before us, realisation may be said to be quite up to expectation. This is no perfunctory text book written to order, but one full of originality, bearing a definite contribution to botany in the shape of a new arrangement of flowering plants (Angiosperms), based upon what the author is bold enough to call their probable phylogeny. Nearly two years ago, in an article published in *The Gardeners' Chronicle* (vol. LXXVI, pp. 8 and 14, 924) on the "Classification of Flowering Plants," reasons were given for the pressing need of a new system, and comments were made on the efforts that were being put forward in this direction by Mr. Hutchinson of Kew. These have now, as it were, crystallised, out—so far as the Dicotyledons are concerned—in this manual. A companion volume on the Monocotyledons, is promised shortly. It will be interesting to see what a fresh and unfettered mind makes of this group of plants which differs from Dicotyledons more in vegetative than in floral features.

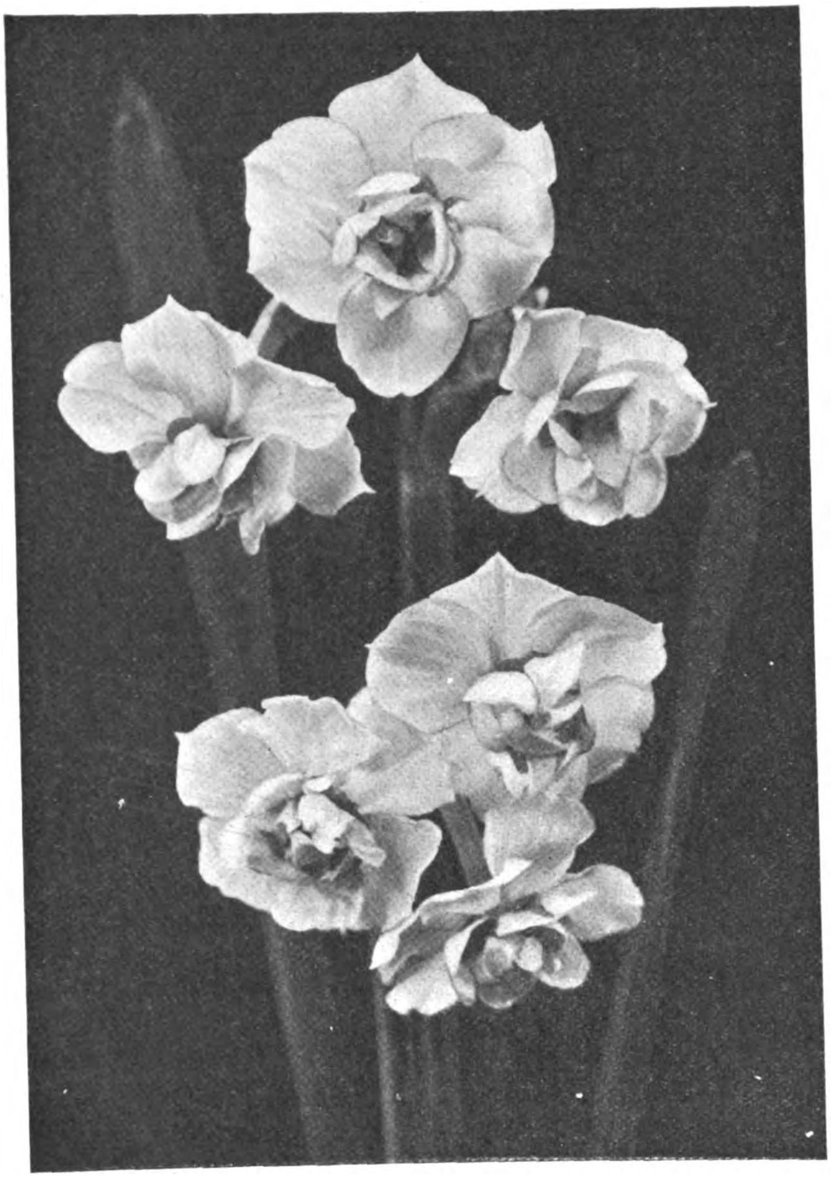

FIG. 84.—NARCISSUS CHEERFULNESS.

R.H.S. Award of Merit, February 23. Flowers cream coloured, with deep yellow, broken corona and yellow bases to the petaloid stamens.
Shown by Mr. J. W. Barr (see p. 162).

Though Mr. Hutchinson professedly aims at a phylogenetic (evolutionary) classification, it must not be assumed that he has reached finality in this matter. It is rather that he has made a beginning, building upon what many of us now think is a sound foundation, viz., that the primitive flower was hermaphrodite and complex in character, consisting of numerous free carpels, stamens and perianth members arranged spirally on an elongated axis—in fact, a flower perhaps somewhat Magnolia-like in appearance. From such a cone-like flower all other types can be derived by various degrees of modification and reduction. Such a view is wholly opposed to Engler's apparent contention that the primitive flower was unisexual, of few parts, and without a perianth. His classification, associated with the name of Prantl, is so based. It has proved unworkable as a phylogenetic system, and it may be no exaggeration to state that owing to its dominating influence the study of the flower has for a quarter of a century been largely in the doldrums. Hutchinson's new scheme, with its definite and clear ideas, should stimulate research in this department of botany. He is anxious for sympathetic criticism, for at the end of his preface he writes: "I shall welcome suggestions which will help to improve the system."

---

* *The Families of Flowering Plants. I. Dicotyledons,* arranged according to a new system based on their probable phylogeny, by J. Hutchinson, F.L.S., Assistant in the Herbarium, Royal Botanic Gardens, Kew. London. Macmillan and Co., Ltd. Price 20s. net.

The book commences with a short, carefully worded "Foreword," by the Director of Kew, though here perhaps the value of the fossil evidence is overstated. Then follow the author's Preface and Introduction—clear and interesting reading. Part of the Preface (most of p. X) would seem more suitable for the introduction; a certain amount of repetition might thereby have been avoided. Emphasis is rightly laid upon a point of considerable importance in taxonomy. A clear distinction is to be drawn between a phylogenetic classification and a key. The one aims at arranging plants scientifically according to their probable evolution; while the other should endeavour to draw out the most easily applied scheme for identifying plants, regardless of artificiality. Systematists in the past, by not keeping their two ideas strictly apart, have often failed to satisfy in either direction.

The phylogenetic system or conspectus is set out in three parallel columns headed as follows:—(i) Notes on Affinity (Origin and further Development); (ii) Sequence of Orders (Cohorts), and Families. A cross line indicates the end of a group; (iii) General Characters and Tendencies of Orders. In addition, the whole system as applied to the Dicotyledons is set forth graphically in an ingenious diagram, or tree, facing page 8. We note, on page 25, one contradiction. The Rubiales are referred to as "a very natural group but *probably derived from more than one source* (reviewer's italics). This is probably a slip of the pen for "not very natural," as in the diagram the order is represented as having a mixed origin.

The artificial Key now follows. This is an effort of some magnitude, and must have cost no little expenditure of midnight oil in its elaboration. By it, with the help only of a pocket lens, it is expected that anyone with elementary botanical knowledge will be able to ascertain the family of any Dicotyledonous plant desired. Useful lists are also given of families with certain constant vegetative features, such as leaves opposite, compound or stipulate.

The main part of the book is naturally taken up with the descriptions of the families. These are given concisely with the outstanding characters in italics. The large numbers of excellent illustrations form a noteworthy and attractive feature. A representative, and often an unusual one, of every family, 264 in all, is figured. The book is thus worth having for the drawings alone. These are from the pen of Mr. Trevithick and the author. In addition, there are numbers of maps showing striking geographical distributions of families and genera. Each description concludes with a list of plants occurring in the family of service to man. Though the important genera are mentioned, a fuller conception of the size of a family would be conveyed by giving in figures the number of genera recognised, and possibly also of the species. In the case of a family consisting of a single species, *e.g.*, Eucommiaceae, this interesting fact might with advantage be definitely stated.

There is a glossary of botanical terms used in the book, as well as an index. The glossary is not quite complete. I fail to find explained such formidable terms as contortuplicate, perulate, strophiolate and syngenesious.

The work is appropriately dedicated to the memory of George Bentham and Joseph Dalton Hooker, and surrounding the inscription is a beautiful floral design (by the author), emblematic of the phylogenetic views expressed in the book. A fascinating exercise presents itself to apply names to the flowers there depicted. Would that the volume could have had a wider margin to set off to full advantage this delightful frontispiece!

The work has been cunningly planned to make as wide an appeal as possible. Besides being a text book for the teacher and student, it should be of much service to the field botanist and forester working in any land. The horticulturist who desires information respecting the affinities and the country of origin of the plants in which he is interested will find this a handy manual.

The book is well printed and the illustrations stand out sharply. In the explanations to these there are a few mistakes, *e.g.*, in Fig. 164, the male inflorescences of Casuarina are labelled female. In the descriptions, the families Frankeniaceae and Malesherbiaceae, have got out of place. These are minor blemishes in a work of so refreshing and original a character, and so obvious as not likely to be misleading. *J. Parkin.*

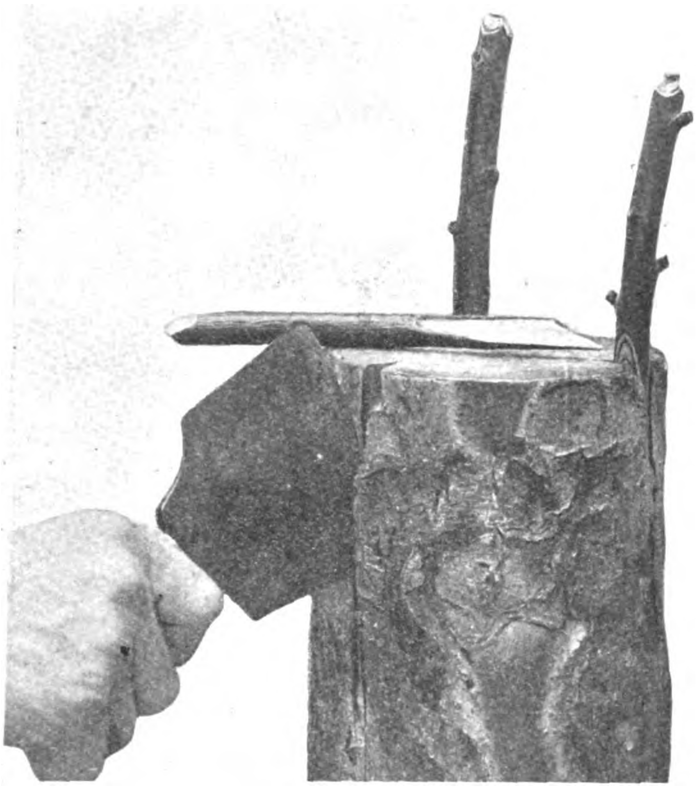

FIG. 85.—STOCK GRAFTING: SHOWING THE SAW CUT.

STOCK OR WEDGE GRAFTING.

Thanks to the kind offices of Mr. J. H. Wootton of Byford, a well-known and respected member of the fruit-growing and judging fraternity, I am able to fulfil the promise given (*Gard. Chron.*, Aug. 15, 1925, p. 134) to describe the almost lost art known variously as Stock, Wedge, Saw or Mallet grafting, when I also alluded to the presumable proficiency in this art of the men of Herefordshire some 300 years ago.

Several years since, Mr. J. Riley, of Putley, told me that he would always prefer to have wedge grafting done when regrafting old trees, but that there were few who could still do it; his predilection being founded on the impossibility of the grafts being blown out. An old grafter, now seventy-four years old, informed me recently that he had given up the method in favour of crown or rind grafting, which was so much easier to do.

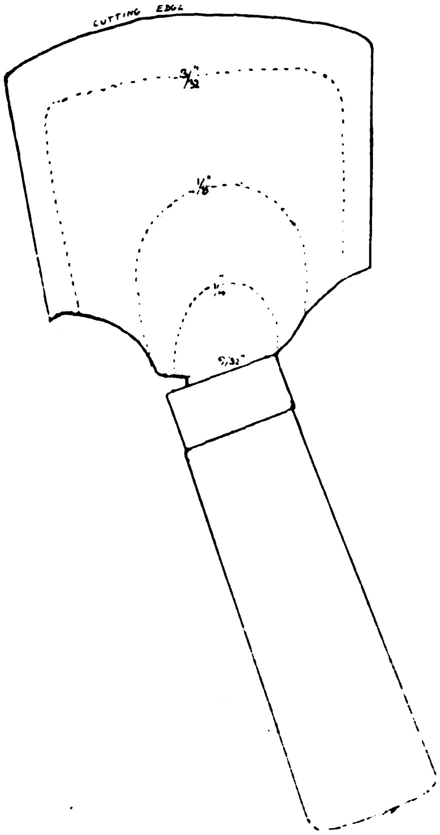

FIG. 86.—STOCK GRAFTING CHISEL.

The method is applicable to the Apple, Pear, Plum, Cherry, etc., and specimens seen of Apple and Plum showed very good unions, the change in bark character being the only indication of the grafting. The trees or stocks are headed back, and the grafts cut some while before hand, just as with any other method of grafting. Operations commence when the sap is on the move, and may be done rather earlier than other procedures, in March.

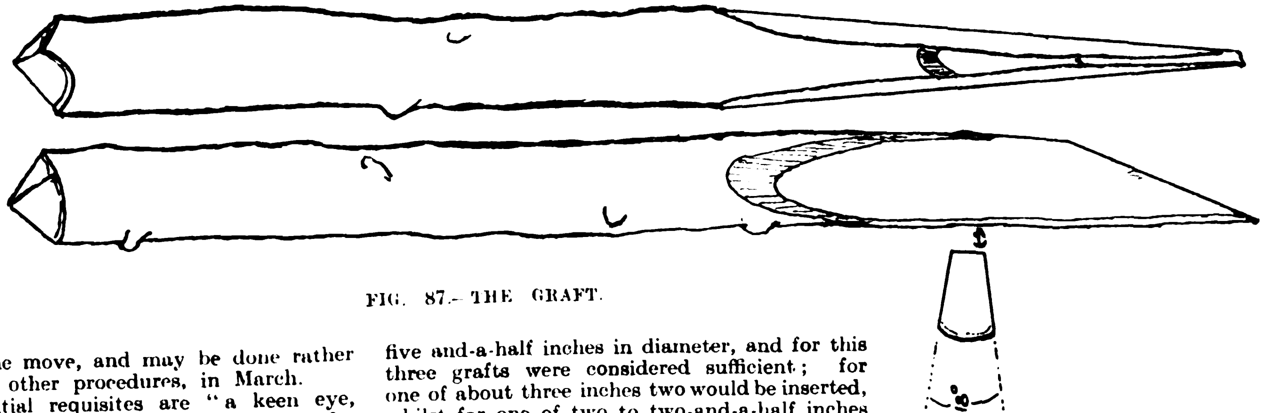

FIG. 87.–THE GRAFT.

The essential requisites are "a keen eye, a steady hand and sharp cutting tools," so far as concerns the operator. The materials, other than grafts and stocks, consist of chisel, knife, saw, and wax or clay mixture. The chisel is the only unusual tool employed (Fig. 86): it has a wide blade, thin, but perfectly rigid. From the dimensions given, any good smith can make a copy; from the figured and dotted lines on the blade the areas of thickness of the steel can be seen, and its thin, tapering blade appreciated. It will be noted that the handle is at an obliquity of 15° with the axis of the blade; the weight is eleven ounces, and that of the blade alone estimated at seven ounces. The blade should be of good steel, well tempered to take a razor-like edge. In regard to the knife, it may be pointed out that the blades of many knives are somewhat concave at the cutting edge, which tends to make a graft cut with them somewhat convex; it is important that the sides of the graft should be flat or plane, so that a straight portion of blade should be used in cutting them. The hand may be steadied against the knee whilst shaving the graft to shape; just as in some other arts the tool may be held still whilst the work is moved, so the knife may be held steady whilst the graft is drawn against it.

Any saw will serve, but inasmuch as the stock is sawn very obliquely from below, it is important that the handle should not project beyond the line of the teeth. The wax or clay, the latter so delicately named *onguent de St. Fiacre* by the French, hardly needs comment; but I think that a good pad of clay may serve to maintain a more equable temperature at the growing junction than a thin layer of wax. Perhaps the perfect seal would be secured by applying wax first and putting on a protective coat of clay afterwards; thus, should rain destroy the clay, when ill-judged in blend, the wax would keep the seal sound. I have often wrapped a few coils of paper around to afford protection against changes of temperature where only wax has been used, and in a chilly spring I have thought that some benefit arose therefrom.

Essentially, the method of stock or wedge grafting is a derivate from the cleft graft, but an improvement thereon, since the extensive damage of the splitting is avoided and the wound is limited to the place of insertion.

I have measured the demonstration grafts which were cut on two separate occasions and found them very closely in agreement. In diameter they were nine-sixteenths-of-an-inch; in length, seven inches; pieces of three-eighths-of-an-inch diameter were judged to be too thin and those of five-eighths rather too thick. For a length of about three inches, flats are cut on either side, tapering from side to side and front to back, that is wedge-shaped, both longways and crossways, in fact, like those cut for cleft grafting. Measurements of specimens showed that the two sides were inclined at an angle of eighteen degrees, *i.e.*, the angle familiar in a razor from edge to back. The inner heel of the graft is further sliced off obliquely to allow clearance from the end of the oblique saw cut. The top end of the graft is trimmed to a pyramid with three cuts, the projecting wood receives the blows when tapping into place. Fig. 87 shows side and back views of the graft cuts.

The stump used for demonstration was five and-a-half inches in diameter, and for this three grafts were considered sufficient; for one of about three inches two would be inserted, whilst for one of two to two-and-a-half inches one only would suffice. In the ordinary course of events, the stump would have been shortened some time before the actual grafting, when it is again sawn off to the desired place: this having been done, the saw is applied at one point and a cut made obliquely upwards and inwards, so that the finished cut extends about three-and-a-half inches down the stem and about one inch towards the centre. The lower corner of the chisel is now placed in the lower part of the saw cut and the blade is swung upwards and inwards so as to remove a thin slice from one side of the cut (Fig. 85). The process is continued, shaving *thin* slices from either side, each chip being removed before the next is cut, until a recess tapering inwards and downwards is made to suit the tapering cut of the graft. Care is taken only to remove a very thin shaving at a time, as well as to clear the view by removing each shaving before proceeding to the next.

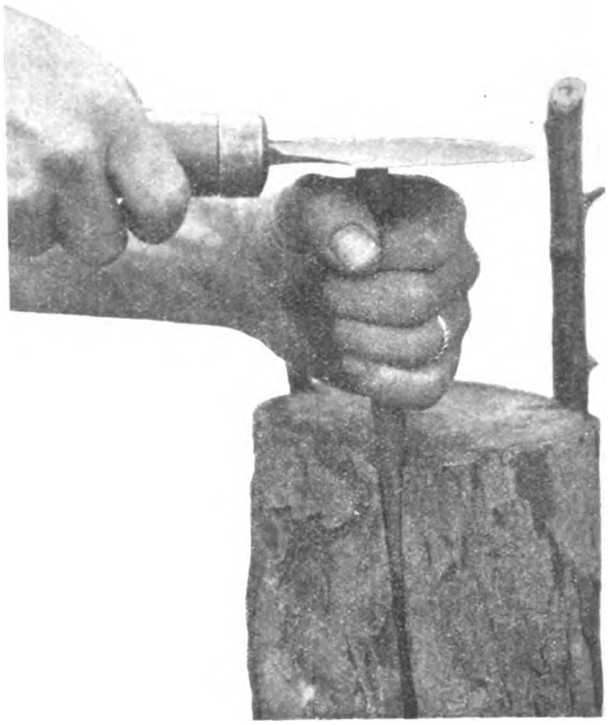

FIG. 88.–STOCK GRAFTING: DRIVING HOME THE GRAFT.

When seemingly nearly correct, the graft is gently tried in the slot; it may then be a question of judgment whether it would be better to slice a trifle off the graft or off the slot; before doing which however, a slight bevel is sliced off on either side of the top of the slot, as shown in the photographs, partly to ease the insertion but chiefly to give a better view when driving in the graft. Driving the graft (Fig. 88) is done by holding it very firmly with the left hand, with careful adjustment so that cambium is opposite cambium. The hand must be ready all the time to counteract a slight outward drift as the top of the graft is tapped home with the flat of the blade of the chisel. As seen in the photographs the summits of the grafts become somewhat burred by the hitting. When inserted the graft should be quite firmly gripped and its cambium in contact with that of the stock. All that now remains to be done is to apply wax or clay. It will be noted that the whole of the cut surface of the graft is not buried in the stock; no doubt the amount left out should not be unduly great.

It will, I think, be clear that a little practice on dummy pieces would be advisable before essaying with the "real things," though this can hardly be done profitably upon dry logs, since the conditions of elasticity etc., have been lost in drying. It would be interesting to see how some subjects (*e.g.*, Walnut) which are rather rebellious to grafting would behave themselves under this method. *H. E. Durham.*

ORIGIN, EARLY HISTORY AND DEVELOPMENT OF THE POTATO.

(*Concluded from page* 159.)

More definite records exist concerning Scotland. In his *Agricultural State of Scotland* (1814), Sir J. Sinclair states that Potatos were first brought from Ireland to the County of Lanark towards the end of the seventeenth century by Major Hamilton of Raplock, but they were very sparingly cultivated for more than sixty years. Sir John goes on: "It is asserted in the statistical account of Scotland, vol. XVIII, p. 282, that Mr. Robert Graham of Tamrawer, in the parish of Kilsyth, and County of Stirling, was the first person in Scotland who cultivated Potatos in the open field, by dibbling and hand hoeing. His first essay, in this husbandry, was in the year 1739, when he planted Potatos by means of the dibble, on about half-an-acre of croft, or old infield land, at Neilston in that parish." In a letter by the Hon. Baron Hepburn, dated 20th March, 1808, addressed to Sir J. Sinclair, and appearing in the *Communications to the Board of Agriculture*, it is stated that Potatos were first imported into Leith in the year 1740, and after that they were for some time grown in gardens only, the first field culture being carried out by a farmer, named Hay, at Aberlady, about 1753 or 1754. The last-mentioned date corresponds approximately with that given by Loudon* for field culture in Scotland. It is to be presumed that both statements are records of fact and that Baron Hepburn was unaware of the earlier introduction. Loudon further adds that a few Potato plants existed about Edinburgh in the year 1725-6, and these were left in the ground from year to year, as recommended by Evelyn, a few tubers being removed for use in autumn, and the parent plants being well-covered with litter to save them from the frost in winter. Loudon remarks that in the year 1796, in the County of Essex alone, 1,700 acres of Potatos were planted for the London market, A study of the Potato in *Rees' Cyclopaedia* 1819, reveals some interesting facts; varietal yield trials had been conducted before the date of publication and experiments with different sizes of seed were made in 1790. It would appear also that manuring experiments on Potatos began so early as 1771.

With regard to the cultivation of the crop, the following extracts will serve the useful purpose of showing progressive early development :—

(A).—*Planters', Florists' and Gardeners' Pocket Dictionary*, by James Gordon, 1774.

"The first thing to be observed in the culture of them is to plow or dig the ground well before winter. If ley-ground is plowed up, it will require two or three plowings before planting, and all roots of perennial weeds gathered out as clean as possible, and cross plowed and harrowed well. If the ground is stiff, it should be laid up in ridges all winter.

"Before the last plowing or digging it should be dunged with half-rotten dung. Some people, where dung is not plenty, lay it in the furrow or trench above or below the Potatos, but it is a bad practice to lay it above. . . . . . Many plant them after the plow, every other furrow, and others miss two furrows according to the goodness of the ground. . . . . . If the ground is digged and the plantation not large, it will be better to plant them with a garden line and dibble, eighteen inches or two feet between the rows, and from a foot or eighteen inches in the rows. The quickest method for planting them is to have a foot-dibble shod with iron pretty thick to go but about five or six inches into the ground. If the line is stretched, one runs along the line with the dibble and another follows and drops the seed into the holes, drawing in the earth with his foot as he goes along"

(B).—*Chambers' Cyclopaedia* (1781).

"The most advantageous way of propagating Potatos is the planting them at large distance, and digging and horse-hoeing the ground several times between them. . . . . .

"In the spring, just before the last ploughing, a good quantity of rotten dung should be spread on the ground, which should be ploughed in the beginning of March, if the season be mild or towards the latter end of the month if there be a probability of frost. In the last ploughing the ground should be laid even, and then the furrows should be drawn at three feet distance from each other, and about seven or eight inches deep. In the bottom of this furrow the roots should be laid at about a foot-and-a-half asunder; then the furrow should be covered in with the earth. About the time when the shoots are expected to appear above the ground, it should be well harrowed over both ways, in order to break the clods, render the surface smooth and destroy the young weeds. The hoe-plough may likewise be introduced between the rows; and this operation should be repeated twice early in the season before the stems of the plants begin to trail upon the ground, and a hoe may be made use of to stir the ground and destroy the weeds between the plants in the rows."

(C).—*Agricultural State of Scotland*, 1814. By Sir John Sinclair.

"1. The universal mode of growing Potatos in the best managed districts is in drills, as described below.

"2. The land gets one ploughing after harvest, with a view of making it mellow, by the influence of the atmosphere during winter. It is cross-ploughed in spring, and gets, or ought to get, as many ploughings and harrowings as are necessary to reduce it into fine tilth, and to remove couch and other vivacious roots."

"3. After the land has been effectually cleaned and reduced, it is formed into hollow drills and ridgelets, and the dung is laid on and spread, in the same manner as already described for Turnips. The sets are laid, by hand, upon the dung, in the bottom of the hollow drills, at various intervals, from four to eight inches; the ridgelets are then split open by the plough, to cover in the seed."

"4. The sets are commonly cut, seldom whole; though some prefer the latter."

"5. Some time after setting, and before the plants begin to push up, the land is harrowed down flat. After the plants are fully up in the rows or drills, the intervals are horse-hoed, and the rows hoed by hand. These operations are repeated at intervals, and, when the plants have acquired some strength, the intervals are split open by the double-mould-board plough earthing up the plants. The cleaning process, however, ought not to continue long, else the crop will be injured by disturbing the radicles when in search of food. And if the soil be kept *too loose* the whole summer, the plants will not bulb well."

"6. They are taken up after harvest in October or November usually by the plough, laying open the drills, when they are gathered, or they are carefully dug up, root by root, with flat-grained three-pronged forks, each digger having one or two children to gather them."

"7. Potatos are stored up for winter in dry, cool out-houses or cellars, covered up with straw, and secured from all access of frost, or in what are called pits, pies or camps."

The Potato is a plant of such economic importance that its history has alway been a subject of great interest; its introduction to this country remains a matter for speculation.

The further history of the Potato is concerned mainly with the development of new varieties; with the struggle against diseases, particularly late blight (Phytophthora infestans); with the improved methods of culture; and with the gradual distribution of the plant throughout the world, due to a universal recognition of its value as a source of food for the human race. *T. P. McIntosh.*

FRUIT REGISTER

APPLE GRAVENSTEIN.

Although not so widely grown as it deserves to be, the variety Gravenstein is worthy of a place in every collection in private establishments.

It is of continental origin and was probably introduced into this country about the middle of the eighteenth century. Unfortunately, this Apple is inclined to be a rather shy cropper. It makes a good standard, and it is in this form that it is most likely to succeed, as I think it resents hard pruning.

Bearing large, pale pink flowers, it is one of the most beautiful of Apple trees when in bloom. The fruit is in season during October and November, and is classified as being both dessert and culinary, but, personally, I think it is far too good to be used for the latter purpose.

The fruit is of medium to large size, irregular in outline; the eye is closed and set in a rather deep basin; the stalk is very short and set in a deep cavity. It is a variety of attractive appearance, the pale yellow ground colour being prettily striped with crimson. The flesh is crisp and juicy and possesses a very refreshing and distinct flavour. *J. Wilson, Wisley.*

TWO RELIABLE APPLES.

For a number of years, I have been greatly impressed by the freedom of cropping and excellent quality of Golden Noble and Galloway Pippin Apples.

Golden Noble is a culinary variety, in season from October to December, but when thoroughly ripe, it is not to be despised as a dessert fruit.

This Apple is of large size and has an even, golden colour ; it has a very white flesh and cooks well. The tree succeeds in the bush or pyramidal form. Brought to notice about 1820, the origin of this fine old variety is uncertain.

Galloway Pippin is a variety of medium to large size, with skin of an even greenish-yellow colour, sometimes with a few minute greyish or brown spots. The flesh is white and of good flavour.

The tree is a prolific bearer, makes clean, healthy growth, and succeeds either as a bush or pyramid. The fruits are in season from November to December.

In the worst of seasons these two varieties rarely fail to carry crops of good, clean fruit. *Ralph E. Arnold.*

VEGETABLE GARDEN.

BROCCOLI.

The hardiness of many green vegetables has been sorely tested this winter. I have no means of knowing how other growers have fared, but I have lost a much larger percentage of plants than for many years past. Brussels Sprouts, Purple-Sprouting Broccoli, the old Cottagers' Kale, and Hardy Green Colewort have suffered the least. All Broccoli, with one exception, Late Queen, have been injured more or less severely ; not a single plant of Late Queen has suffered. Some growers rely on a few good kinds and make successional sowings. I have always found safety in numbers, and select varieties that naturally succeed each other, although sown and planted out at the same time.

I make two sowings of Broccoli, the first about the middle of March and the second about the middle of April, according to the variety. June is the month in which most plantations of Broccoli are made, when the ground can be cleared, yet it is frequently July before the work can be done. My plants were set out at the end of June and early in July, two feet six inches apart, some on ground which had been cleared of early Potatos, and others on ground which was cleared of a three-year-old bed of Strawberries. I always select the poorest and firmest soil for this most important crop with most satisfactory results, as rich soil produces tall plants with soft stems, and leaves which suffer wholesale in a severe winter. The mild, wet autumn of 1925 has no doubt had a great deal to do with the present mortality. Last summer twelve varieties were planted, and those on the Potato ground heeled over before frost occurred in order to check growth and harden the plants. The stems were well covered with soil and made firm, although I did not consider my plants tall or gross in any respect. "Heeling" is largely practised in the north, but many growers in the south consider this operation unnecessary. I did not, however, follow up this precaution with some form of protection, by Bracken or other rough material, as is often done. There is little difference in the losses of these Broccoli and those planted on the Strawberry ground without any other attention.

The value of heeling over Broccoli is overestimated by growers, for not only is much labour wasted, the size of the heads are considerably diminished thereby. I am more firmly convinced in my opinion every year that this protection is unnecessary. The plants in fields are generally dwarf and hardy, but only last week I noticed more vacancies than usual in fields several acres in extent. The past winter has not been one of the severest, but quite severe enough to injure the Broccoli crops on heavy, wet ground. Varieties grown are Superb Early White, Veitch's Self-Protecting, Snow's Winter White, Backhouse's Winter White, Knight's Protecting, Leamington, Perfection, Satisfaction, Late White, Methven's June, Model and Late Queen, the last standing out alone on our cold soil as the hardiest in this selection. Model, Methven's June, Knight's Protecting, Backhouse's Winter White and Leamington are the hardiest of the other varieties. *F. Jordan.*

HOME CORRESPONDENCE.

Does Frost Kill Insects?—All my observation goes to confirm Mr. Nicholson's opinion that a hard winter is favourable to insect life (page 122). It need not, I think, be hard enough to "decimate" the birds, as he suggests ; all that is needful for the protection of subterranean larvae, such as leather grubs, wireworms, etc., and the pupae of these and other species under ground, is that the frost should be hard enough to prevent the use of plough or spade. Now that the ploughs have got to work again, it is pretty to watch the seagulls crowding close at the heels of the ploughman in search of tit-bits whereof there is no scarcity in the freshly-turned furrows. The most rigorous winter in my experience was that of 1894-5, when severe frost endured from early in January until the middle of March. I have it noted that in the succeeding summer insect life, both aquatic and terrestrial, was unusually abundant. *Herbert Maxwell, Monrieth.*

Rabbits and Heaths.—In reply to *T. C.'s* enquiry on page 125, I know, to my cost, that rabbits eat newly-planted Heaths greedily. If, however, the plants are protected with wire-netting until they have become well-established and begun to spread, they may hold their own just as the common Ling and Bell Heather grow freely where rabbits abound, though some of the plants may be nibbled pretty closely. Much depends upon what other supply of food the rabbits can turn to. *Herbert Maxwell, Monreith.*

——It may help *T. C.* (p. 125) to know that on the commons around here rabbits are very plentiful, burrowing freely amongst the Heather, but they do not appear to feed on it. Rabbits often get into our garden and have attacked Broom, Gorse, Veronica, rock plants, Cedar, Holly, fruit trees, Crocus, etc., but have not touched any of the varieties of Erica growing near-by. Were rabbits severely limited for food no doubt they would attack Ericas, but while they can find plants of a more succulent nature, I do not think they would feed on the wiry stems of Heaths. *R. Gardner, Cobham.*

Gardening—an Old Profession.—There appears to be a deliberate attempt on the part of a few new owners of estates to belittle the honourable profession of gardening. Years ago a gardener was nothing but a domestic servant, true, of an "upper" kind, but with the great advance of knowledge in horticultural matters the type has changed, and gardening is on the up-grade still. As proof of this, I have received numerous requests from gentlemen to take and train their sons in gardening, and if further proof be needed it is surely to be found in the Wisley Gardens of the Royal Horticultural Society, where a considerable number of students are in training. Obviously the parents of such students are not having their lads trained in order that they may earn thirty shillings a week as gardeners! The parent of to-day is not inclined to pay a premium for the training of his son unless there are good prospects. I am sure there is a future, and a brilliant one, for those who are genuinely keen, able and original. All this goes to prove that notwithstanding the fact that many large estates are being broken up, there is always a demand for the right man. But it has taken many years to arrive at the present status of our profession, and my experience has been that gardens and estates are crowded with labourers. I cannot tell how many estates I know where I have personally investigated the facts and found a really experienced head gardener saddled with a staff of incompetents who have been there for years and cannot easily be got rid of. There are other places where no one will suit either the gentleman or the lady, who believe their knowledge is so great that there is really no need for an experienced gardener. There are people who are always changing their staff, will not pay a fair wage, and persistently treat gardeners as domestics. Against all this gardeners must wage war unceasingly. Every gardener should stand for his profession, first obtaining all the horticultural knowledge he can, keep abrest of the times, and so help to make gardening a progressive and enduring profession. *Bruce D. Hewitt.*

Iris unguicularis.—Although strictly true, it seems hardly fair to Iris unguicularis to state that the flowers are "too tender for packing for travelling," as mentioned in Mr. Harrison's note in your issue of February 20. The opened flower is no doubt too tender to travel by post ; but, if the buds are picked when the petals are still unrolled, they are extremely easy to pack, travel excellently, and open in a few hours after being put into water. The reference to the note in *The Gardeners' Pocket Diary*, published by the R.H.S., recommending that the leaves of this Iris should be cut back to half their length in May or early June, might also have gone a little further. Where this Iris is planted in ordinary garden soil the cutting back of the leaves has an extraordinary effect on the production of flowers, because, I take it, the summer sun can shine on the soil about the roots of the plant and give them a good baking. But where I. unguicularis is planted under a wall facing south and the soil is of the very poorest (as it should be) the growth of the leaves is not nearly so strong, and the necessity for cutting them back is not so obvious. Mr. Dykes, however, used always to recommend that the leaves should be cut back, if for no other reason than that it was much easier to get rid of the snails in the autumn ; these pests infest the plants and are a great nuisance, and unless cleared away will eat every bud as it comes up. Powdered alum, scattered among and around the plants, prevents a lot of damage by these pests, and does not injure the plants in any way. It may be well to add that in picking the buds care should be taken not to cut them too low down, especially in the case of those which flower early in the season, because dormant buds which will flower later may easily be damaged. *Charles T. Musgrave, Hascombe Place, Godalming.*

Early History of the Potato.—In addition to the interesting facts mentioned by Mr. McIntosh on p. 159, the following may be recorded In the old *M.S.S.* at Belvoir Castle it is recorded that King James I paid a visit to Belvoir on August 7, 1612, with the Prince of Wales, and had six whole meals there, and that twenty Potato roots were purchased for that event. Unfortunately, the price is not stated, although most of the other expenditure is given with great care. The company on that occasion appears to have been very numerous, as fifteen oxen, steers and heifers were purchased ; fifteen muttons, 116 lambs, etc., etc. The item of Potatos appears under the heading "Expenses of spice at the King's being there." Cowcumbers, two barrells ; Samphor (Samphire), two barrells ; Hartechoakes, six dozen ; Quinces, one barr cont. 104 ; Oringes, 200 ; Ryse, £20, are also mentioned ; and among presents, "Pears, two baskets, from Mr. Markham of Sydebrooke (Sedgebrooke) ; Rewardes, six shillings," presumably to the messengers, which must have been on a very liberal scale, as wages were very low in those days. At a previous visit of the King in 1603, I find "Paied to Sampson Scoffyeld, of Wollisthorpe, for fourteen days to set up tentes and lattinge downe agayne and makinge tente pynes againste the Kynge's com'ynge to Belvoyre at 4d. the day, 3s. 6d. ; and to John Warner, for fyve days carringe breade to the Castell, 12d." *W. H. Divers, V.M.H.*

Lobelia cardinalis.—A correspondent (p. 96) states that a slightly-heated pit is needed for the protection of Lobelia cardinalis in northern gardens. In my opinion, the plant needs a season of rest. One specimen still in the open here is quite unharmed after experiencing 25° of frost. Those stored in frames are protected only from wet, which is far more detrimental to their welfare than frost. *Charles Hodgson, Acton Place Gardens, Sudbury.*

Onions.—I was greatly interested in Mr. Gregor Roy's criticism (p. 86) of Mr. Copley's method of growing Onions. I have seen excellent results from Mr. Roy's method of culture, but I prefer sowing Onions thinly in boxes, and when large enough to handle prick the seedlings off into boxes (not pots) using a compost consisting of one part loam, half-part leaf-mould, silver sand and a little wood-ash. Gradually harden the seedlings and plant them out about mid-April, nine inches apart in the rows which should be one foot asunder. The ground should be trenched deeply and dressed with farmyard manure, adding a good dressing of wood-ash and soot a few days previous to planting. As regards feeding, I think Mr. Copley has greatly overdone it by advising as a first dressing, one ounce per bulb of superphosphate 30 per cent; a quarter-ounce is plenty, gradually increasing to half-ounce per bulb, later giving a dressing of nitrate of soda to stimulate leaf development. Keeping the bed well supplied with water in dry periods during the growing season, giving an occasional dusting of soot during showery weather, and using the hoe on every possible occasion are other details of importance. *W. Thomas, Day House Gardens, Shrewsbury.*

I am sorry that an error crept into my manuscript. The sentence Mr. Thomas refers to should read as follows :—" During the first fortnight, the formation of roots is encouraged by four applications of superphosphate (30 per cent.) at the rate of half-an-ounce per plant " *Geo. H. Copley.*

Tetrachlorethane as a Glasshouse Fumigant.—I am sure that many readers of *The Gardeners' Chronicle* will be grateful to Mr. G. Fox Wilson for his illuminating and helpful note (page 138) on this subject. He has covered the ground so thoroughly that little remains to add. I should be interested to know if the fumes of tetrachlorethane are likely to be more toxic if the house is dried off prior to fumigation. It occurs to me that the fumes would not be impeded in their action so much as would be the case if the plants were covered or partly covered by a film of water. Will Mr. Wilson inform me if the species of white fly which attack Gorse is the same as the one that occurs on greenhouse plants. There are certain areas in the county of Glamorgan, near the sea, where numerous colonies of white flies are found on Gorse every year. I have no work of reference which indicates a species peculiar to the Gorse, and examination reveals no specific difference. If it is definitely known that this plant is concerned with the spread of white fly it might be possible to induce landowners to burn the Gorse and thus help to rid our gardens of a terrible pest. *Geo. H. Copley, N.D.H.*

GARDENS AT OLYMPIA.

As is usual at the Ideal Home Exhibition, a large annexe at Olympia is again devoted to gardens, and the present display is one of the best of the series.

The most attractive and pleasing garden is the one arranged with great skill by Messrs. James Carter & Co. The general scheme is a low hill-side with a winding stream in the valley-foreground, into which water descends from three waterfalls and pools. Rocks, suitably planted, are used with artistic restraint on either side of the moving water, which gives life to the whole picture. Pines and other Conifers serve as background and flanking groups, adding dignity to the design. Several varieties of Daffodils, with a few flowering Cherries, Dielytra spectabilis and Azaleas are grouped effectively in the foreground in a natural and uncrowded manner, while on the upward slopes Erica carnea is massed around a rocky outcrop on the one side and Primulas fill a little plateau below the rocks on the other side. A few choice Conifers add grace and colour on the higher parts of this charming garden picture.

The circular Italian garden, arranged by Messrs. Luff and Sons, is finely planned, and the pergola-like entrances to the central pool and fountain are admirably constructed and beautiful in themselves. Between these entrances forced flowering shrubs in great variety and beauty are planted in wide borders, which are equally attractive on both sides. Hyacinths are associated with the shrubs and used with great freedom, indeed, in our opinion, the fine design is somewhat spoiled by an excess of good things. A pleasing rock-garden is also provided by the same firm.

Mr. G. Whitelegg has ingeniously contrived to combine two distinct gardens in his allotted space, each a complement to the other, and so arranged that the colouring of the Azaleas, Wistarias and Lilies in the shrub garden is not seen from the admirable rock garden. A winding path leads from one garden to the other, and in so doing passes over high ground that effectively but very naturally divides the two. The Mollis Azaleas and standard Wistarias are very fine in the shrub garden, while Saxifraga Irvingii, S. Faldonside and a colony of Primula denticulata alba arrest attention in the rock garden.

Messrs. J. Cheal and Sons have on view a delightful garden house suitable for a fairly large estate, and they have also a formal Yew-hedged garden with central pool and paved walks, with beds of Hyacinths set in the green turf. Outside the hedge are borders of choice shrubs wherein Rhododendrons, Ericas, Laburnums, Viburnum Carlesii and Pernettyas are planted effectively.

Messrs. L. R. Russell have a design for planting the whole width of a villa garden, at the end farthest from the house. A rustic, Clematis-clad arbour, with low steps leading thereto, is the central feature; on either side of this early-flowering trees and shrubs are planted, these including the fragrant Viburnum Carlesii, Rhododendron praecox, Lilacs, Magnolias, and other subjects, some in standard form and others as bushes. Acacias and tall Cordylines behind the arbour are effective, but not in keeping with the general design. Near-by, Messrs. Allwood Bros. have a formal garden with beds of Carnations; large lead urns at the entrances are also filled with Carnations. The whole effect is quiet and pleasing.

Messrs. R. Wallace and Co. present a combined rock, water and shrub garden, with a rustic summer house that seems rather too large for the area planted. A dove-cot is another feature. One of the most pleasing items of this garden is in the outer corner, where Snowdrops, Crocuses and Primroses are grouped naturally below thinly-planted trees. Messrs. Reamsbottom show what may be done with Anemones, and their formal garden planted solely with these beautiful spring flowers may suggest similar plantings where Anemones are firm favourites.

Capt. Crewdson Day has a formal garden with paved paths and central pool of water and four beds of blue Hyacinths. His rock garden did not attract us greatly, and we did not admire the use of close turf, cut in squares and set diagonally around the rocks. Mr. Reginald Winder has a pleasingly designed Rose and Carnation garden with a surrounding hedge of Lonicera nitida—showing the value of this shrub for a low, stiff hedge—and rambling Roses on chains and pillars; sunshine is needed to give effect to this garden.

A very quiet and restful garden arranged by the Orpington Nurseries makes a strong appeal to many visitors, and is a striking contrast to some of the more gorgeous displays. Rock and water, green turf and Heaths, Saxifrages and Primulas are all pleasingly associated, and a stroke of genius is the little group of Birches with simple Primroses and Snowdrops covering the ground beneath. Other gardens of interest are Mr. Pinney's Violet garden, in which Primula Jewel assists its fragrant sisters; the rock and shrub garden arranged by the Central Garden Supplies, Ltd., and the same firm's rockery bank, which suggests a method whereby owners of small gardens may grow a fairly large collection of alpines in a small space; and lastly, the Dutch Tea Garden, wherein Messrs. J. Carter and Co. have planted Hyacinths and Daffodils as a foreground to the scenic painting which represents a bulb farm in Holland, with its accompaniment of windmill, canal, distant village and the familiar long, stretches of Hyacinth beds.

SOCIETIES.

LINNEAN.

At a meeting of the Linnean Society on February 18, Mr. J. Ramsbottom, Botanical Secretary, displayed a number of air photographs which showed " fairy rings " on the downs around Salisbury. The photographs were loaned by Mr. O. G. S. Crawford, Archaeology Officer to the Ordnance Survey, well-known for his investigations on the avenue of Stonehenge and on Celtic fields. The dark rings in pastures are of very frequent occurrence and are usually realised to be associated with fungi. The name " fairy-ring " suggests another association which Conan Doyle has somewhat ingenuously supported by saying that although the rings cannot have been formed by the dancing of fairies they would offer a very charming course for a circular ring-a-ring dance. There is much folk-lore connected with fairy-rings. In some countries it is lucky to step into a ring; in others, luck favours those who keep out. The dew on the grass of some or other part of the ring is beneficial to a maiden's complexion—or to her love affair.

Coloured slides of rings of Tricholoma gambosum were shown and diagrams explaining the mode of their production. In former times, thunder, lightning, moles, haystacks, and so on, have been regarded as the causal agents, but the lecturer did not support these hypotheses. The rings are formed by the growth of the fungus mycelium or " spawn." A spore, on germinating, gives rise to a mycelium which, if there are no obstacles, spreads equally in all directions. These fungal filaments as they spread consume a portion of the organic material of the soil; the carbohydrates are used up or reduced, and part of the protein is converted into ammonia; and eventually nitrates. These nitrates are available as plant food for the higher plants and stimulation of growth results. In this way is formed the outer ring of stimulated growth so common in rings on pastures. The manuring of the soil with the consequent increase in growth results in greater demands upon moisture. But the increase of growth of the mycelium, probably owing to filling the air spaces, makes the soil impervious to rain water, and causes a physiological drought. The result is that the grasses and the flowering plants die and leave a bare zone which is attributed to dancing fairy feet, or in German tradition to the scorching caused by a fiery dragon lying down to rest after his nocturnal wanderings. The compacted mycelium dies after a few years and leaves the soil still more enriched and no longer impervious to moisture. Grasses and flowering plants invade the area and show stimulated growth. This three-zoned ring—an outer and inner stimulated zone with a middle bare zone—is the most frequent type. The theory of ring formation is that of Shantz and Piemeisel: the hypothesis of parasitism to account for the bare patch is discounted by the fact of regular growth. A matter of interest with the downland rings is their rate of growth, because it may be used in estimating certain changes in vegetation. The rate of growth apparently depends upon the species forming the ring and upon weather and soil conditions. Measurements are remarkably few and discordant. Shantz and Piemeisel found that in Colorado the mycelium of Psalliota tabularis and Calvatia cyathiformis grew on an average about 12 cm. annually, and estimated the age of rings at 250 and 400 years respectively: fragmentary rings, if arising from a single ring, would be 600 years old. The largest complete ring in the photographs was 350 feet in diameter, and assuming the rate of growth to be 12 cm. annually, would be more than 400 years old.

The paper was followed by one of more academic interest. Prof. F. O. Bower outlined a scheme of phyletic grouping of Ferns. This was illustrated by lantern slides which enabled the audience to visualise the evidence. The criteria of comparison were detailed, leading to a précis embodying the most archaic characters. This " archetype " is substantially similar to the Psilophytales of the Devonian. It is probable that in the course of descent a gradual transition took place from the Eusporangiate to the Leptosporangiate state. In the phylogenetic tree, as constructed, Ferns with distal or marginal sori are placed on the left, while on the other side are those in which the sori are superficial, a state that is regarded as a secondary result of a widened leaf surface; the marginal is probably the primitive position. This grouping results in the separation of the Dicksoniaceae and the Cyatheaceae.

An interesting sequence is shown in the middle line of the scheme, Osmundaceae—Plagiogyria—Gymnogrammoideae, but the details need the volumes promised us for their proper discussion.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

THURSDAY, February 4.—*Committee present;* R. Ashworth, Esq. (in the chair), Messrs. C. Branch, A. Coningsby, D. A. Cowan, J. Cypher, J. Evans, G. Giles, A. Keeling, E. W. Thompson and H. Arthur (Secretary).

FIRST-CLASS CERTIFICATES.

Cypripedium Aureoma, Haddon House variety (*aureum* × *Desdemona*).—A flower of perfect shape; the ground colour of the dorsal sepal is green with a brown centre and broad white margin; the broad petals are greenish-yellow, the lip of a rather paler shade. From Mrs. M. SMITH.

Cattleya Vesta var. Puritan (*Snowdrop* × *Lady Veitch*).—A beautiful snow-white flower of good shape and texture. From J. B. ADAMSON, Esq.

Odontoglossum crispum, Grand Duke Nicholas.—A flower of the Doin type, white, with reddish-brown spots on the lip. From S. GRATRIX, Esq.

Cypripedium Evansiae (*Desdemona* × *Memoria Jerninghamiae*).—A fine flower; the dorsal sepal is pure white with a solid patch of reddish purple at the base; the upper half of the petal is reddish-brown and the lower half light yellow; the lip is reddish-brown. From Mr. JOHN EVANS.

Cypripedium Pathan (*Eurybiades* × *Mirum*).—A large, bold flower; the broad dorsal sepal has rose-purple spots on a white ground; the broad petals and lip are reddish-brown. From Messrs. KEELING AND SONS.

AWARDS OF MERIT.

Odontioda Juno var. Margaret; *O. Colinge var. J. B. Adamson*; *O. Bonar Law.*—From J. B. ADAMSON, Esq.

Cypripedium Ashton (*Christopher* × *San-Actaeus*).—From Mrs. M. SMITH.

GROUPS.

J. B. ADAMSON, Esq., Blackpool (gr. Mr. R. Taylor), staged a group for which a Gold Medal was awarded.

A Gold Medal was also awarded to S. GRATRIX, Esq., Manchester (gr. Mr. C. Branch), for a group including choice Cypripediums.

A large Silver-gilt Medal was awarded to the Hon. G. E. VESTEY, Southport (gr. Mr. B. Collins), for a miscellaneous group. A. HANMER, Esq., Buxton (gr. Mr. G. Giles), staged a group of Orchids to which a Large Silver Medal was awarded. A Silver Medal was awarded to Messrs. J. CYPHER AND SONS, Cheltenham.

FRIDAY, February 19.—*Committee present:* Capt. W. Horridge (in the chair), Messrs. H. Astley Bell, R. Ashworth, C. Branch, A. Coningsby, D. A. Cowan, J. Cypher, J. Evans, A. Keeling, E. W. Thompson and H. Arthur (Secretary).

FIRST-CLASS CERTIFICATES.

Odontoglossum Exworth var. Duke of York (*eximium* × *Aireworth*).—The sepals and petals are reddish-purple, the lip white with a dark blotch. *Odontioda Colinge var. Rosemary.*—A beautiful flower; the sepals and petals are coloured ruby-red with narrow white margins; the lip is white with a red blotch. A Silver Gilt Medal was also awarded. Both from J. J. BOLTON, Esq.

Odontioda Margaret (*ardentissimum* × *Bradshawiae*).—A fine flower of rich madder red.

Brasso-Cattleya British Queen, var. Leviathan.—A flower of good, even colour, with broad, well-set petals. The lip has a deep blotch and a yellow throat. Both from J. B. ADAMSON, Esq.

AWARDS OF MERIT.

Odontioda Sensation var. splendens (*Vuylsteakeae* × *Odm. crispum*): and *O. Mars var. Tigrina* (*Charlesworthii* × *Lawrenceanum*). From Mrs. M. SMITH.

Cattleya Clotho, Adamson's variety and *Odontoglossum Nora* (*illustrissimum* × *Dora*). From J. B. ADAMSON, Esq.

Odontoglossum Garnet var. Prince Charming (*Amethyst* × *crispum*). From J. J. BOLTON, Esq.

GROUPS.

J. B. ADAMSON, Esq., Blackpool (gr. Mr. R. Taylor), was awarded a Gold Medal for a group.

Large Silver Medals were awarded to groups exhibited by S. GRATRIX, Esq., the Hon. G. E. VESTEY and Messrs. J. CYPHER AND SONS, respectively.

Obituary.

G. Wallace Sinclair.—Mr. G. Wallace Sinclair, gardener to F. W. Cooper, Esq., Oulton Park, Tarporley, Cheshire, died under tragic circumstances from burns received while in the act of carrying out a valuable picture when the mansion caught fire; the roof suddenly collapsed and trapped him in the burning room, and although his son nobly extricated him from the flames, his burns and other injuries were so severe that he passed away on February 15. Mr. Sinclair's character was beyond reproach. He was a favourite with everyone he came in contact with. He was a first-class gardener and an able judge. Had the war not intervened his abilities as a Grape grower would have brought him to the front, as he had been preparing to produce Grapes from young vineries he had made at Peckforton, where it was my pleasure to see some of the finest finished Grapes in the British Isles. Mr. Sinclair served his apprenticeship at Nortonthorpe Hall Gardens, Yorks, under Mr. Finney, and went as journeyman under Mr. E. C. Plislow, Shadwell Court. Norfolk, then as foreman to Mr. Holway, Doneraile Court, Cork, and afterwards as fruit and plant foreman under Mr. John Munro at Falkland Park, South Norwood. His first appointment as gardener and steward was with Major Nichols, Kilbrack, Co. Cork, where he remained for five years, when he became gardener to Lord Tollemache, Peckforton Castle, where he served with distinction as farm manager during the war. Later, he took up an appointment as steward and gardener to C. J. Lamb Esq., Forest Hay, Sandiway, and he went to Oulton Park in January, 1926. Mr. Sinclair leaves a widow and two sons to mourn his loss The remains were interred at Whetton cemetery, Northwich, on February 19, and the funeral was attended by many hundreds of friends The death of Mr. Sinclair is a great loss to horticulture. *Robert Greenfield.*

THE LATE G. WALLACE SINCLAIR.

ANSWERS TO CORRESPONDENTS.

ARUM LEAVES DISFIGURED.—*P. L.* The blackish growth on the leaves of the Arums is produced by a fungus (Cladosporium), growing on the honey-dew deposited by aphides. Use a suitable insecticide to dispose of the green fly and afterwards cleanse the foliage.

BRANCHED TULIPS.—*The Grange.* Branched Tulips are not uncommon and specimens were illustrated in *Gard. Chron.*, May 15, 1909, p. 317. Branching is said to be due to division of the flower-forming tissue at a very early stage of the plants development.

FUCHSIAS AND SCENTED PLANTS.—*M. P. J.* The following are some good double Fuchsias with white corollas:—Ballet Girl, Sylvia, Dainty Lady, Molesworth, Mrs. E. G. Hill and Pink Pearl, with fiery pink sepals and corolla; six good singles are Mrs. Roberts, Mrs. Rundle, Flocon de Niege, Lustre, Amy Lye and Alice Hoffman. For scented plants you could grow Heliotropes, Freesias, Aloysia citriodora (the Lemon-scented Verbena), Perpetual-flowering Carnations, Hyacinths, Paper White Narcissus, Jonquils, Mignonette, Boronia megastigma, Daphne indica, Rhododendron Lady Alice Fitzwilliam, and the scented Pelargoniums, such as P. fragrans, P. Radula, P. capitata, P. crispum and P. quercifolium. We are in doubt as to whether you require the plants for a greenhouse or for a dwelling room.

NAMES OF PLANTS.—*H. P. W.* 1, Clerodendron Thompsonianum; 2, Epiphyllum truncatum; 3, Begonia species; send when in flower.

NARCISSUS BULBS FAILING TO FLOWER.—*C. H.* From the appearance of the flower buds we suspect that your treatment has been at fault, and that the trouble is not due to unsatisfactory bulbs. Unless Daffodils have been grown in cool conditions in the early stages of forcing and the pots well-filled with roots before they are introduced to a warm house, they usually fail, as in your case. Next season, endeavour to get the plants well-rooted by growing them in cool conditions, such as in a bed of ashes in the open or plunged in a cold frame, before bringing them into the forcing house.

PINE APHIS OR PINE CHERMES.—*D. S.* The insect on the bark of your Pines is the Pine Aphis (Chermes corticalis), a very troublesome pest. All that you can do is to spray the trees with a paraffin wash at intervals of six or eight days, over a period of two months during the late spring.

PUTTING GREENS.—*G. C.* In order to provide the greatest amount of pleasure for players a putting-ground should not to be level nor anything like level. On the other hand, pronounced obstructions in the form of "bunkers" are quite out of place, as the object of such grounds is to encourage a proficiency in putting and not in hitting. An ideal putting ground is one that has an undulating but well-kept surface. One of the most difficult public putting-grounds we are acquainted with is set out on a gently sloping lawn where to "hole" the ball successfully requires considerable skill. An area of three-quarters of an acre will provide, if carefully set out, space enough for eighteen holes.

SOIL FOR CHRYSANTHEMUMS.—*J. P.* We do not undertake to analyse soil for our readers. If you think the compost is unsuitable or something has been added causing injury to the plants, you still have time to obtain fresh cuttings, or if you are too late with some varieties, young rooted plants may be purchased very cheaply. In view of your suspicions, we advise you to see that no one has access to the house in which they are grown except those who are responsible.

REMARKS.—Owing to the improved weather conditions much larger supplies have been received from all quarters during the past week. Very heavy consignments were received on Wednesday and Thursday of last week from the Channel Islands and the west of England, consisting mostly of Daffodils, white and yellow Narcissus, Violets, Anemones and Tulips. Of the home-grown Daffodils, Emperor, Victoria, Barrii and King Alfred are realising the best prices. Amongst Tulips Darwins are receiving more attention owing to their very fine quality. The varieties include Wm. Copland, Clara Butt, Bartigan, Elizabeth, Pride of Haarlem, Wm. Pitt, Farncombe Sanders and Le Notre. Roses are increasing in quantity almost daily; the varieties Columbia, Madame Butterfly, Hoosier Beauty, Sunburst and Richmond are much easier in price owing to a much larger supply. Snowdrops are practically finished for the season, but the quantities of Violets exceed the present demand. Sweet Peas are becoming more plentiful.

REMARKS.—The volume of business transacted is very satisfactory, trade, no doubt, being helped by the much improved weather. English Apples are almost finished, excepting for those still in cold store. Imported Apples are also less plentiful. South African fruits continue in good demand and generally they are in good condition. The bulk of those received from the Cape consist of Peaches, Nectarines, Plums and Pears. Grapes are not so plentiful and are selling fairly well. Tomatos from the Canary Islands are in firm request, and Bananas from the same source are also a good trade. Cucumbers have benefited by the brighter weather; good prices are obtained for them. Forced Beans are a steady trade, supplies being mainly from Guernsey and the Worthing district. New Potatos from Guernsey are more plentiful but are maintaining a good price. Forced Rhubarb has been a poor business all the week, increasing quantities of outdoor Rhubarb no doubt being responsible for the reduced values. A larger amount of Asparagus from France is available and is selling fairly well. Consignments of Cauliflowers from northern France are still heavy, and this, with large supplies from Guernsey and the west of England, has brought down values somewhat. Mushrooms are abundant and comparatively cheap. Salads are wanted and selling freely. Green vegetables are in demand. Trade in old Potatos is slow.

GLASGOW.

THE cut flower market developed weakness, which was most acute on Tuesday, and while a slight recovery set in on Friday, prices reflected material losses on the weeks' trading. Guernsey Daffodils arrived in great quantity and the condition of Tulips was affected by the spell of mild weather. Highest and lowest prices are recorded in the following list of Tulips:—Bartigon, W. Copland, Prince of Austria and Couronne d'Or, 8d. to 1/-; Ibis, 10d. to 1/-; Flamingo, Lucretia and Farncombe Sanders, 9d. to 1/-; Tea Rose and Murillo, 7d. to 10d. for best, and 3d. to 7d. for ordinary; Azalea, 1/3 to 1/6; Salmonette and Vuurbaak, 1/- to 1/3; Rose Tendre, 10d. to 1/-; Thomas Moore, Yellow Prince and Gris-de-lin, 6d. to 8d. Guernsey Daffodils sold at 1/- to 2/- per dozen bunches. English-grown princeps, Golden Spur and Sir Watkin, 6d. to 8d. per bunch; ornatus, 3d. to 6d. and Narcissi, 1/- to 2/-. Mimosa was worth 1/- to 2/6 per pad; Carnations, 1/6 to 2/6 per dozen; Lily-of-the-Valley, 1/3 to 1/6 per bunch; English Violets, 6d. to 1/- per dozen; French Violets, 1/- to 1/6 per pad; and Parma Violets, 1/- to 2/- per bunch. Richardias (Guernsey) sold at 2/- to 3/- per dozen. Lilium longiflorum (Harrissii), 3/- to 4/- per bunch; Smilax, 1/- to 1/6; and Asparagus Fern, 6d. to 1/3. Hyacinths in bowls made 1/6 to 2/- each; and strong Wallflower plants, 1/- to 1/6 per box.

The tone of the fruit market was dull generally and movements in values were towards a lower level. Prices for Oranges were irregular, certain counts being dearer and others cheaper; 360's and 504's ranged from 12/6 to 14/- per half-case; 300's, 14/- to 18/-; 240's and 200's, 15/- to 20/-; 420's, 18/- to 23/-; large, 20/- to 42/-; 714's, 18/- to 26/-; Jaffa, 144 and 152, 18/- to 20/-; 136's, 17/- to 20/-; Californian Navel, 26/- to 32/-; and Grape Fruit, 26/- to 40/-. South African fruit was in good demand at the following quotations:—Peaches, Freestone, 7/- to 9/-; Alberta, 5/6 to 7/-. Pears, Williams's Bon Chretien, 4/3 to 6/-; Louise Bonne of Jersey, 4/6 to 6/-; Plums, Satsuma, 6/- to 7/-; Kelsey 6/6 to 8/6; Californian Winter Nelis Pears averaged 17/- per half-case. English Gros Colmar Grapes made 3/- to 5/- per lb., and Belgian, 2/- to 2/6. A quiet but steady business was reported in Apples at the following values:—British Columbia: Jonathan, 10/6 to 12/6 per case; Grime's Golden, 8/- to 9/-; Spitzenberg, 9/6 to 12/-; Delicious, 13/- to 15/-; Oregon: Newtown, 13/- to 15/6; Winesap, 11/- to 14/6; Delicious, 14/- to 16/6; Spitzenberg, 9/- to 11/6; United States: Greening, 26/- to 36/- per barrel; York Imperial, 28/- to 34/-; Ben Davis, 14/- to 18/-; Gano, 15/- to 20/-; Baldwin, 14/- to 20/-; Albemarle, 26/- to 40/-; Nova Scotia: Russet, 16/- to 23/-; Ben Davis, 12/- to 14/-; Baldwin, 12/- to 16/-; Canadian: Greening, 28/- to 34/-; and Baldwin, 20/- to 26/-.

In the vegetable section Asparagus averaged 7/- per bunch; Paris Green, 8/-; Sprue, 1/6; Endive, 3/- to 4/- dozen; Seakale, 2/6 to 3/-; French Lettuces, 3/6 to 4/- (outdoor-grown), 1/6 to 2/- (indoor); Salad, 2/6; Radishes, 4/- to 4/6; Syboes, 7/-; Artichokes (white), 1/9 to 2/- per stone; Cucumbers, 1/5 to 1/8 each; and Rhubarb 36/- to 40/- per cwt.

CATALOGUES RECEIVED.

J. CARTER AND CO., Raynes Park.—Farmers' Guide.

SUTTON AND SONS, Reading.—Farmers' Year Book.—Garden equipment.

CIVIL SERVICE SUPPLY ASSOCIATION, LTD., 425, Strand, W.C.—Seeds and garden requisites.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 41·9.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office 5, Tavistock Street, Covent Garden, London, Wednesday, March 10, 10 a.m. Bar. 30·5. Temp. 48°. Weather, Bright, with cold wind.

Insect Pests of the Cabbage.

THE longer a man cultivates his garden and the more he studies the voluminous literature on garden pests, the surer grows the conviction that in the rotation of crops, both in the vegetable quarters and in the seed-bed, lies the chief means of securing for his plants a reasonable immunity from disease. This being so it should always be the endeavour of the gardener to carry out rotational cultivation to the fullest extent possible; changing each year not only the location of the vegetable crops, but also that of the seed beds and frames and the soil itself in which the seedlings are raised. Consider, for example, the plants of the Cabbage tribe, which form such an important source of vegetable supplies. The mycologist and entomologist have drawn up a truly formidable list of the fungous and insect pests which attack these plants—some in the seedling and some in the adult stage. There are, for example, finger-and-toe and the damping-off fungus (Rhizoctinia), and there are the Cabbage maggot or root fly (known sometimes as Hylemia brassicae and sometimes as Phorbia brassicae), the larvae of which make long tunnels in the roots; and the Cabbage gall weevil which causes rounded, tumour-like swellings on the roots of Cabbage and of Turnip, simulating—albeit in a more regular way—the distortions of growth caused by finger-and-toe. Then there are the leaf-destroying enemies—the Cabbage butterflies—the Large White and Small White (Pieris brassicae and Pieris rapae) which sometimes appear suddenly in vast numbers and riddle the leaves till all their tissues are devoured. It is, of course, a happy garden in which none of these pests occur in such numbers as to cause serious loss, but in most gardens less auspiciously absolved from epidemics, vigilance and forethought may prevent the occasional severe losses which neglect of these garden virtues is sure to entail. Finger-and-toe should, of course, never appear at all in the private garden. It is a disease of poor, light, lime-hungry soils. Yet there are many gardens on light, sandy soil in which the pest does make its appearance. Where it does, the best remedial measures are those directed to the improvement of the soil. It is stated that something may be done to prevent the disease from attacking seedlings by applying a weak solution of corrosive sublimate to the seed bed. A quarter of an ounce of finely-powdered corrosive sublimate dissolved in four gallons of water appears to prevent infection if applied early enough and if the dose be repeated once or twice. Care, however, must be exercised that the solution be not too strong. This remedy—or partial remedy—for finger-and-toe has been applied also, with very considerable success to the protection of plants of the Cabbage tribe from the Cabbage maggot, attack by which pest often leads, particularly in market gardens in America, to great loss of seedling plants. The most recent experiments* in the prevention of loss from this cause, have shown that by watering the seed-bed with corrosive sublimate, one ounce to ten gallons of water, applied at the rate of one gallon to twenty--forty feet of row, the damage caused by this pest may be reduced to negligible proportions. For the method to succeed, the first treatment should be applied so soon as the plants are well through the ground. With spring-sown Cabbage, this should be about May, at which period the small, greyish fly, looking very like a slender and very active house fly, is busy laying its eggs at the base of the seedling Cabbage plants. Inasmuch as poisons such as corrosive sublimate soon lose their potency when mixed with soil, two further doses at weekly intervals are generally necessary. Another precaution that may be adopted is to dip the seedlings at transplantation time in water or a very weak insecticide. The effect of this treatment is to dislodge the glistening white eggs attached to the bases of the plants. The auther of the *Bulletin* just cited has also found that the maggot may be deterred from attacking the seedling Cabbages by giving a liberal dressing of Tobacco dust to the seed bed. The dust, which is applied at the rate of one pound to thirty—forty feet of row, has proved an excellent means of reducing attack by the Cabbage maggot and appears, moreover, to favour the growth of the seedlings, so that the manurial value of the Tobacco dust may compensate somewhat for the cost of applying it. There remains, of course the method much practised by market growers in New York State, of covering the seed bed with cheese cloth, and there is also the tarred disc method which consists in protecting the soil at the collar of each plant with a suitably cut, tarred-disc. Lastly, it is to be remembered that systematic cultivation of the ground, such as is practised by all good gardeners, is of all means the most important for ridding the ground of pests. By it large numbers of pupating inimical insects are exposed to the weather and to the attention of birds, and it would be well for gardeners on light land, who are inclined to leave digging until spring, to remember that by deferring this work, though they may perhaps gain advantage in other directions, they lose the benefit of the winter and spring cleaning which attends on autumn digging.

Afforestation of the Richmond and Gordon Estates.—Some fine work has been accomplished during the winter months in the planting of large areas around Gordon Castle, Fochabers, Morayshire, the chief Scottish seat of the Duke of Richmond and Gordon. Not only will forestry benefit, but the large amount of labour entailed has given welcome employment to large bodies of men during the most critical labour period of the year. The work has been done mostly at Ortagar, and at the part of Slorach's wood burned down in 1919. In all there have been nearly 130 acres planted this season, each acre taking 4,500 trees. All were supplied from the finely equipped estate nursery, the plants being in excellent condition. Mr. Clark, head forester, under whose supervision the work was carried through, again adopted the favourite system of "close space planting," contending that it has always given the best results in the Gordon Castle woods. It may be interesting to note that during the past ten years the Duke of Richmond and Gordon has planted over 1,000 acres, the plants required numbering over five millions. Would that all our big-landed proprietors were in a position to do likewise.

Exports of Potatos from France.—The French Ministry of Agriculture has made regulations similar to those in force last year, providing that between March 1 and May 1 new Potatos may only be exported within the limits of a quota. The quota for each centre of production may not exceed ninety per cent. of the average quantity exported during the past three years. The Potatos must be accompanied by a certificate, issued by an authorised association, and containing a declaration that the fixed quota has not been exceeded. Imports into this country of Potatos from France in March and April last year were 128,135 cwts., followed by 1,357,238 cwts, in the following two months, practically all of these coming in June.

Horticultural Lectures at Chiswick.—The Chiswick Public Library and Museum Committee has arranged for a course of three lectures on horticultural subjects to be given at the Chiswick Public Library. The course is as follows: Thursday, March 11, "Garden Flowers," by Mr. John Weathers, Isleworth; Thursday, March 18, "The Cultivation of Vegetables," by Mr. Wm. H. Johns, N.D.H., superintendent of the Bermondsey parks; and Thursday, March 25, "Out-door Chrysanthemums," by Mr. Charles H. Curtis, F.L.S. Admission is free and the lectures begin at 8 p.m. sharp.

Forthcoming French Horticultural Events.—The annual spring exhibition of the French National Horticultural Society will be held at Cours-la-Reine, Paris, from the 28th of May to the 6th of June. The programme will be substantially the same as in 1924. The work of demolition of the buildings erected on the site for the Exhibition of Decorative Arts last year is proceeding apace, and exhibitors will be glad to be back in their old position. As mentioned in our issue of February 6th (p. 92), the French Chrysanthemum Exhibition is to be opened on November 4, at Blois; it is to last until the 9th of the month, and will be of an international character, English, Belgian, Swiss and Italian growers being asked to exhibit. Besides Chrysanthemums, which will be the main feature, there will also be exhibits of fruits, vegetables, fruit trees, and ornamental shrubs. The venue of the Federation of French Horticultural Societies has now been definitely fixed at Rheims, and the dates provisionally as July 5th to 7th.

---

* "Control of the Cabbage Maggot in the seed bed." By Hugh Glasgow. *Bulletin* No. 512, of the New York State Agricultural Experiment Station, Geneva, New York.

Traffic Problems and the London Parks.—A suggestion that certain parts of Hyde Park should be utilised—together with adjacent streets—for the purpose of dealing with London's traffic problems, has caused a good deal of uneasiness among those who are anxious there should be no spoliation of the open spaces of the metropolis. A statement made in the House of Commons by Col. W. Ashley, Minister of Transport, serves in some measure to allay any fears in regard to this matter; he said he would not countenance the turning of London Parks into traffic channels, and that he would deprecate any action which might interfere with the amenities of Hyde Park, unless a case of overwhelming necessity arose.

Increasing our Timber Resources.—Under the auspices of the Edinburgh University Forestry Society, Mr. Harry George Younger, who gave the estate of Benmore to the nation, delivered an address on "Timber Growing," in which he urged on various grounds the importance of greatly increasing our timber resources. He mentioned that between sixty and seventy million tons of timber were imported last year into this country, to pay for which a considerable amount of money had to be sent abroad. He left it to the professors and the Forestry Commission to tell them what proportion of that amount might have been grown in this country; certainly a third and possibly a half, without restricting our food supplies by more than an infinitesimal amount, and no one could deny what a great economic gain that would be. In forestry, more than anything else, it was of vital importance that they should learn their work from the elementary stage upwards. In 1914, just before the war, they had a visit from the leading continental forestry experts, and M. Parde, the well-known French expert, told them what he had seen was a revelation to him. While they could not say a great deal about our sylviculture, our arboriculture they thought wonderful, and his opinion was, that a good many species of Conifers could be grown on the western side of Scotland at nearly double the speed they could be grown in any other part of the world, and that was true. Great forests could be grown in Scotland comparatively rapidly, but it would be necessary for the forester to take the scientist along with him. Changed conditions were continuing to arise, and new diseases seemed to be affecting trees. Referring to taxation burdens, Mr. Younger said the taxation following the war had completely upset his forestry ambitions. What had prevented him from planting was the increasing cost of it, and the knowledge that on the small scale on which he could do it, the planting cost per acre was so high as to make it foolish to try. Planting costs must be kept low if a wood was to pay. After a strenuous commercial life of over forty years, experience told him that the man who learned his job thoroughly came out on top. If he were starting planting again and was looking for a good forester he would not choose a man because he knew the Latin name of every species, but the man who could tell a well-grown tree from a bad one, and who could be relied on to grow his own trees well. The chief blessing in this world was good health. Wealth, land, success of all kinds were worth nothing without good health, and in the very nature of it a foresters' occupation must be the healthiest of all. At the annual dinner of the Society, held in the evening, Mr. Younger announced that he desired to commemorate his hon. presidency by presenting a gold medal to the best student each year.

Mr. F. G. Cousins.—Mr. Cousins, who recently returned to his native Devon to take charge of the beautiful and interesting public gardens at Torquay, is well known to horticulturists in and around London, having been Superintendent of the Royal Botanic Gardens at Regent's Park for five years. The difficulties at Regent's Park, on account of conflicting desires and lack of funds necessary for the proper maintenance of the Botanic Gardens, are notoriously great, but with admirable tact and professional skill Mr. Cousins overcame difficulties and maintained the gardens in a much more efficient condition than he found them. In addition to his legitimate work as chief of cultivation, the supervision of the training of students, the arrangements for flower shows and other functions, and contributing valuable articles periodically to the *Journal* of the Society, Mr. Cousins made time and somehow found space in the already restricted glasshouse accommodation to grow "the Spices of the Indies," as well as Palms and other decorative plants which the West Indian authorities sent over for the embellishment of their garden at the British Empire Exhibition (1924) at Wembley. At times, the condition and season in which these plants reached London taxed Mr. Cousin's cultural skill almost to the utmost, but how well he overcame the difficulties was fully apparent to the numerous visitors who admired the beautiful and interesting exhibition garden at Wembley. Mr. Cousins was trained at Kew, entering from Exeter in 1906, and became sub-foreman of the Orchid Department. Soon after leaving Kew he was successively an Inspector of Plant Diseases for the Kent County Council and a Deputy Inspector in the Horticultural Department of the Board of Agriculture. For a comparatively short time before taking up the Regent's Park appointment, he organised the Potato and Show Departments of Messrs. Bees, Ltd., at Liverpool. He is a member of the R.H.S. Floral Committee and carries with him to Torquay the good wishes of many professional friends and their confidence that he will find in a district with such a kindly climate abundant scope for his abilities.

MR. F. G. COUSINS.

Sweet Pea Annual for 1926.—Sweet Pea enthusiasts always look forward to the publication of the *Sweet Pea Annual* by the National Sweet Pea Society, while members of the Society become restless if the publication is delayed. The present issue contains much that is interesting, but we do not admire the arrangement of articles, and suggest that the more important subjects should occupy the more prominent positions. Educational subjects, cultural or otherwise, are omitted; this is to be regretted because in so important a Society there are always numerous recruits who appreciate such articles from experts. Mr. Lester L. Morse contributes critical observations upon the show held in 1925; Mr. G. H. Burt reviews the same exhibition and his "asides" are as interesting as his criticisms. "Sweet Peas in Vancouver Island" is from the pen of Mr. Lumley Perrier, formerly an enthusiastic Sweet Pea grower in England. Mr. Yuille discusses "Sweet Peas in Scotland," and Mr. E. R. Janes makes a strong appeal for increased membership of the N.S.P.S., and points out how provincial members could help in this important matter. In addition to the Report of the Floral Committee for 1925, Mr. C. H. Curtis contributes a Report of the Henry Eckford Memorial Fund, a breezy biographical notice of Mr. Andrew Ireland and the obituary notes of two old and valued members—Mr. Whitpaine Nutting and Mr. Horace J. Wright. Considerable space is occupied by records of the Society's proceedings, names and addresses of members and, of course, there are the Classification Lists and the List of Too-Much-alike varieties, all of great value to Sweet Pea lovers.

Veitch Memorial Medal for Alpines.—As announced some weeks ago, the Council of the Royal Horticultural Society offers a Gold Veitch Memorial Medal for the best exhibit of alpines in pots staged by an amateur at the show which will be held at Vincent Square on March 23rd and 24th. Intending exhibitors are reminded that application for space should reach the Secretary, R.H.S., Vincent Square, S.W.1, not later than by the first post on Wednesday, March 17.

Moulds and Mildews.—This was the subject of Professor Drummond's fourth and last lecture of his series on "Town Botany in Winter," delivered at Glasgow University on the 6th inst. under the auspices of the Workers' Educational Association. Discussing the vast group of fungi which were either parasites obtaining their nourishment from other living organisms, usually plants, or saprophytes which lived on dead organic matter, he explained the composition of the Mushroom, which represented the most familiar type of fungi. Only green plants have the power of independent nutrition, and it was a peculiarity of fungi that they were not green. After a passing reference to disease-producing plants, the lecturer commented on Black Rust in Wheat which did not pass from one year's crop to the next direct, but only through the medium of the Barberry. Yellow Rust common to cereals was caused by a fungus. Smut of Wheat was due to a fungus reproduced in enormous masses inside the ripening grain. Smut of Barley, he said, was controlled by washing the seed in formalin or hot water and had practically vanished in most European grain-producing countries. Canker of trees next came under the lecturer's observation and when speaking on Wart Disease of the Potato he explained that it was due to a fungus which found its way to the cells of the Potato, thereby setting up an irritation which caused the warted structure. The spores may be in the soil for seven or eight years, and so far it had been found impossible to kill them. The common moulds which appear on old bread and cheese, over-ripe fruit or other stale foodstuffs, and the Yeast plant, were described as saprophytic fungi. In conclusion Professor Drummond said that the main purpose of the lectures was to suggest there was ample scope well within the confines of a great city, and at an unpromising time of the year, for personal observation of many different aspects of plant life. Personal observation, he said, is the essence of scientific knowledge. Books and lecturers were helpful in putting the student on the right track, but what was thoroughly learned was what one discovered for oneself.

Crocuses naturalised in Grass.—A large breadth of Crocuses naturalised in grass is one of the prettiest features in gardens and parks at this time of the year, and these harbingers of spring give great pleasure to all classes, and especially to town dwellers. Many of our public parks have been gay with these pretty flowers during the past few weeks, and such places near the metropolis as Kew Gardens, Hyde Park and Hampton Court have been visited by large numbers especially to inspect the Crocuses. The winds have been a little unkind to the flowers and they are on the wane, but still very attractive in many favoured spots; an especially pretty spot in Hyde Park just now is the bank of Crocuses near the Ranger's Lodge, whilst several other patches under the trees and elsewhere are to be found in the enclosures near Hyde Park Corner, and at the back of the flower walk in Kensington Gardens. The illustration in Fig. 89 shows many thousands of Crocuses in bloom in Hampton Court Gardens, and as it is the custom now to have special days for special flowers, a Crocus day, as well as a Horse Chestnut day, is associated with this old-world park and garden. It will be seen that many of the Crocuses are growing beneath large trees, and in such positions they not only appear to advantage, but succeed admirably, for by the time the trees are draining the soil of its moisture, the Crocuses are in their resting stage.

Scholarships for Agricultural Workers.—The Ministry of Agriculture announces that under the scheme for establishing scholarships and maintenance grants for the sons and daughters of agricultural workmen and others, a number of scholarships tenable at University Departments of Agriculture, Agricultural Colleges and Farm Institutes, are offered for award this year. The scholarships are limited to sons and daughters of agricultural workmen and of other countryside workers in similar financial circumstances, and the awards cover all reasonable expenditure involved (tuition, board, outfit, travelling, etc.). Provided a sufficient number of suitable applicants is forthcoming, ten Class I Scholarships will be offered for the degree courses in agriculture or horticulture, or for the course of M.R.C.V.S. at the Royal Veterinary College; ten Class II Scholarships for two-year diploma courses in agriculture, horticulture, dairying and poultry-keeping at Agricultural Colleges; and about one-hundred-and-twenty Class III Scholarships for short courses at Farm Institutes. Forms of application and full particulars of the scholarships may be obtained from the Secretary, Ministry of Agriculture and Fisheries, 10, Whitehall Place, London, S.W.1., or locally from the Offices of County Councils. The last date for receiving applications is April 30. This scheme was approved in 1922 for an experimental period of five years, and this is the last offer of awards under the experiment. After the selection of scholars for the present year has been completed, the question whether or not the scheme should be continued will be considered.

Scotch Potato Sales.—The fourth annual sale of seed and ware Potatos organised by Messrs. Smellie and Sons, Hamilton, was held on Friday of last week, when consignments were offered from a wide area extending from Morayshire in the north to Peebles in the south. Chief interest centred in a lot of the new variety Arran Consul, offered by Mr. Donald McKelvie, Lamlash. After spirited bidding, the tubers were sold at £60 per ton, thus making the top price of the market. Other prices were as follow:—Kerr's Pink, 77/-; Golden Wonder, 100/-; Great Scot, 90/-; Arran Comrade, 97/-; Arran Chief, 72/6; Immune Ashleaf, Tinwald Perfection, Epicure and Sutton's Abundance, 75/-; King Edward, 90/-; Sharpe's Express, 77/6; Dalhousie, 80/-; and British Queen, 52/6. A number of lots of ware Potatos realised from 40/- to 60/- per ton. At Messrs. Lawrie and Symington's sale there was a brisk demand for seed grown in the district, and up to 106/- was paid for Majestic, 101/- for Arran Chief, 97/- for Epicure, 70/- for British Queen, and 91/- for King Edward. The sales aggregated 375 tons.

Exhibition of Garden Design.—The Royal Institute of British Architects is proposing to arrange an exhibition of drawings, prints, plans and photographs, illustrative of garden design, in their galleries during April, to include designs of gardens old and modern, public and private, British and continental. The exhibition will continue from April 7 to April 21, and a lecture on "Garden Design" will be given by Mr. F. Inigo Thomas, F.S.A., on April 14, at 5 p.m. Members of the R.I.B.A. who have in their possession prints, photographs and drawings (measured or otherwise) which are suitable for this exhibition, are invited to submit them for the consideration of the selection committee. The following conditions are to be observed:—(1) The exhibition is intended primarily to be one of garden design and planning but illustrations of garden architecture and ornaments, such as orangeries, pergolas and statuary, may be submitted if desired. (2) Exhibits should be in reasonably good condition for exhibition purposes. (3) Photographs should be as large as possible, unless they are submitted merely to illustrate a plan, and should be mounted. They need not be framed. (4) All exhibits should be clearly marked with their title and the owner's name and address. (5) Exhibits should be addressed to the Secretary, Royal Institute of British Architects, 9, Conduit Street, London, W.1., and must be received by him not later than March 20. (6) All exhibits will be insured against all risks while in possession of the R.I.B.A.

A New Appointment at Twickenham.—At a recent meeting the Twickenham District Council appointed Mr. P. R. Sillwood Cemetery Superintendent and Gardener at a salary of £190 per annum, rising to a maximum of £230 with emoluments valued at £35. This new appointment becomes an established post for the purposes of superannuation. For the past six years Mr. Sillwood has been assistant superintendent to the Watford Joint Burial Board.

Dresden Horticultural Exhibition.—The Jubilee Exhibition to be held at Dresden, from April to October this year, promises to be of the utmost interest. Planting and preparations of all kinds have been steadily carried on for a year past, and the exhibition grounds have already assumed the aspect of a huge garden. As at Haarlem last year, the period of the exhibition has been divided, and six special shows will take place according to the plants which are expected to be at their best during the time fixed. The first show, at the opening of the exhibition, on the 23rd of April, will be for spring flowers, which will be staged in several of the large exhibition halls. Azaleas and Rhododendrons are expected to be the great features of this show. Throughout the whole period of the exhibition certain halls will contain scientific and technical exhibits of a nature to be interesting and helpful to horticultural visitors. A little later, when the weather is warm, the outside sections of the exhibition—the Roses, herbaceous plants, etc.—are likely to receive the most attention. A display of Tulip and Narcissus novelties from Dutch and German growers, an open-air theatre, and a number of other features will combine to attract many thousands of visitors to the exhibition.

Appointments for the Ensuing Week.—Tuesday, March 16: Winchester Gardeners' Associations' meeting. Wednesday, March 17: Royal Gardeners' Orphan Fund Committee meet. Pangbourne Gardeners' Mutual Improvement Association's meeting and lecture. Friday, March 19: Manchester and North of England Orchid Society's meeting. Saturday, March 20: British Mycological Society's meeting.

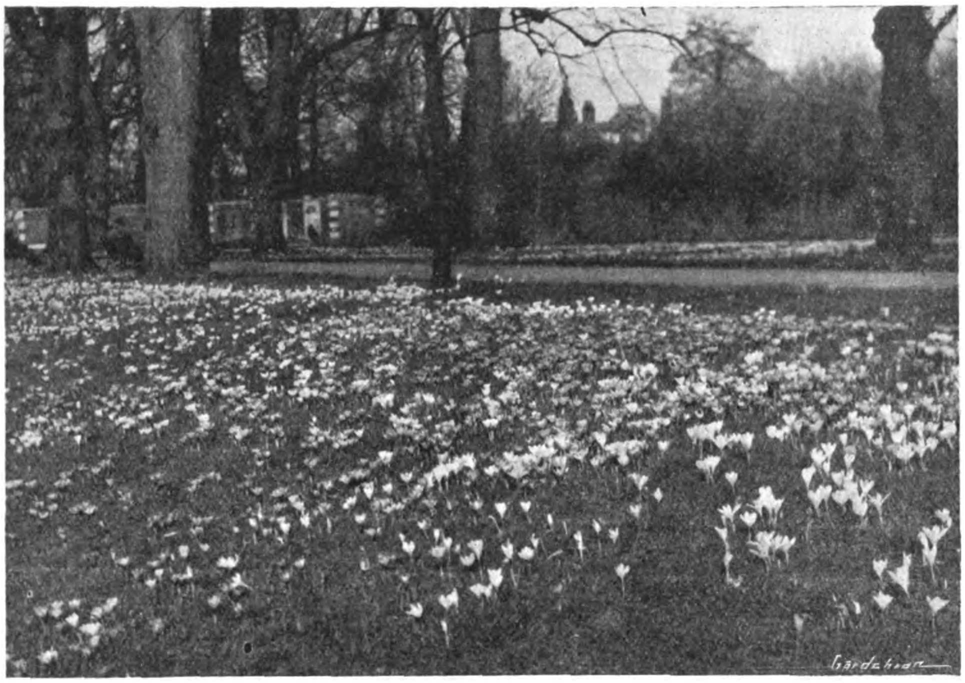

FIG. 89.—CROCUSES NATURALISED AT HAMPTON COURT

"Gardeners' Chronicle" Seventy-five Years Ago.—*Amherstia nobilis and Victoria regia.*—We learn that the beautiful Amherstia nobilis has flowered at Frogmore. The first raceme was taken to Buckingham Palace on the 7th inst., and we anticipate that another will have expanded before this time. In the cultivation of this plant, Mr. Ingram has found it necessary to constantly shade it from the rays of the sun, otherwise the young pendulous leaves are apt to get their edges scorched. It grows luxuriantly in a moist heat of from 65° to 70° Fahr.; it likes a good supply of water, and sometimes a little manure water. We understand that the Victoria Water Lily has been blooming in Messrs. Veitch's nursery, Exeter, for these three weeks past, during which time it has produced nine blooms. To Messrs. Veitch, therefore, belongs the credit of having first flowered this interesting plant in a nursery. It occupies a tank fifteen feet broad, and has seven leaves on it, some of which are reported to have been upwards of four feet in diameter. The water in which it grows is kept in continual motion, by means of the revolutions of a small wheel. Flower buds continue to make their appearance, and in all probability there will be a succession of blooms for some time to come. *Gard. Chron., March* 15, 1851.

The Week's Work.

THE ORCHID HOUSES.

By J. Collier, Gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

Management of the Houses.—With the advent of March there will be a daily increase of light and sunshine, and each division will require more attention in regard to ventilation and atmospheric moisture. There will be a gradual activity amongst the plants, both as regards development of flower and growth. Owing to the more favourable outside conditions, the temperatures of the houses may range a few degrees higher than hitherto, both night and day.

Shading.—It will now be necessary to have the blinds or other shading material fixed on the houses ready for use, as the sun will increase in power each day. In the coolest division the temperature, under the sun's influence, will rise quickly above what is necessary for the well-being of the plants. The growths and leaves that are now developing are very tender and will soon become scorched and disfigured if they are too freely exposed to bright sunshine. Discretion must be exercised in the use of the blinds. It is advisable to be on the safe side by not unduly exposing the plants to the sun's rays; at the same time, they should not be shaded more than is really necessary.

Ventilating.—Cold winds ofttimes alternate with bursts of bright sunshine in March, the external temperature being perhaps 40° or more below that in the warmer houses. Under these conditions it is not advisable to admit fresh air in sufficient volume to keep down the temperatures. On such occasions use the blinds. When the outside temperature rises to 45°, the amount of ventilation may be increased and shade afforded with discretion. These remarks apply more especially to the cooler houses containing such plants as Odontoglossums, Masdevallias and cool-growing Cypripediums. The Cattleya and intermediate houses will only require shading for an hour or so during the middle of the day until the season is further advanced. Any inmates of these houses that require more shade should be placed at one end and be shaded independently. Many occupants of the East Indian house, such as Phalaenopsis, Angraecums, and the warm-growing Cypripediums will require protection from the sun.

THE KITCHEN GARDEN.

By F. Streeter, late Gardener to Major Albert Pam, Wormley Bury, Broxbourne.

Tomatos.—Where Tomato plants are required for outside planting the seeds should be sown now in well-drained six-inch pots and in a sterilised compost if possible. Raise the seedlings in a temperature of about 50° at night and 60° by day. So soon as the seedlings are large enough pot them singly into sixty-sized pots filled with rather sandy soil. Grow the plants sturdily at all times. They will quickly root in the new soil, and so soon as they are fit transfer them to six-inch pots, using the following compost: two-thirds fibrous loam, one-third old Mushroom-bed manure, and sufficient road grit and sand to render the texture porous. Should the loam be deficient in lime a little of this material should be added. Grow the plants steadily and give them plenty of ventilation when outside conditions are favourable. The first truss should be set by the last week in May, when the plants should be set out in their final quarters if the weather is favourable.

Celery.—The main sowing of Celery should now be made in boxes of fine soil, according to requirements. Treat the seeds with formalin, as recommended by the Board of Agriculture, for combating rust disease, which is increasing yearly. Sow very thinly and raise the seedlings in a moist atmosphere. From the time of seed-sowing to digging the drop, Celery should never be allowed to suffer from want of water at the roots. The earliest sowings are ready for pricking off into other boxes or frames, or, in the case of plants required for exhibition, placed in small sixty-sized pots.

Globe Beet.—Early supplies of Beet may now be easily had by sowing in cold frames over a mild hot-bed of leaves covered with about six inches of fine soil. These young roots are much superior to the old roots of last season's main crop. Admit a little air on the leeward side of the lights early in the mornings and close them about three o'clock, first gently spraying the frame with tepid water.

Brussels Sprouts.—Brussels Sprouts require a long season of growth, and I strongly advise sowing now in boxes and raising the seedlings in gentle warmth. The seeds will germinate very quickly, and the seedlings should be pricked out into other boxes or frames so soon as they are ready. Grow them sturdily at all times.

THE FLOWER GARDEN.

By F. C. Puddle, Gardener to Lord Aberconway, Bodnant, Taly-Cafn, North Wales.

Ivy.—Ivy on screens and walls should now be trimmed. It is not good practice to allow a superabundance of growth to extend from the walls as it has a tendency to make the latter damp, and when cutting takes place an unsightly appearance is inevitable. If annual clipping is practised at this season the plants will be clothed with new growth in a short time.

Galtonia candicans.—Bulbs of this handsome Liliaceous plant may now be planted in a well-drained soil and sunny situation. Plant the bulbs six inches deep and from nine inches to twelve inches apart. Galtonias are quite hardy provided the soil in which they are grown is thoroughly drained. If, however, the position is damp, the bulbs should be lifted in autumn and stored in dry soil for the winter.

Ericaceous Plants for the Rock Garden.—The introduction of many dwarf Rhododendrons and allied genera from China and Tibet, has greatly widened the choice of small shrubs suitable for the rock garden. In a lime-free soil the cultivation of these plants presents no difficulty, but when the soil is calcareous the problems of successful culture assume a more perplexing form. The practice of excavating the soil and filling in with peat, leaf-soil and sand is, at its best, only a temporary measure, for the lime-impregnated water from the surrounding soil, percolating through the bed, soon renders the whole mass unsuited to the plants. A better and more permanent method would be to make the whole bed above ground level. The outline may be formed with peat turves and the centre filled in to an average depth of about one foot six inches, with a mixture consisting of equal parts of leaf-soil and peat, with not less than one-fifth its bulk, of silver sand. The sand is an important ingredient. Sea sand should not be used, as the small particles of shell contained in it would introduce lime and render the whole work of no avail. Undulations, for the purpose of providing shady nooks, may be formed by building ridges faced with stones (avoiding limestone), and filling in with the prepared compost. If suitable stones are not available, moderately sharp ascents may be made with peat turves, and these planted with dwarf-growing Ericas, Vacciniums and Gaultherias, such as G. trichophylla, G. nummularioides and G. Veitchiana, in addition to Rhododendrons. A selection of dwarf Rhododendrons for the more exposed parts of the bed includes the violet-purple R. rupicolum, R. verruculosum and R. nigropunctatum, the slightly paler R. impeditum, and the lavender-blue R. intricatum, R. fastigiatum, with the taller-growing R. hippophaeoides, the yellow R. chryseum, the purplish-mauve R. scintillans and R. parviflorum. For the most sheltered places select R. Sargentianum, a compact-growing plant with small yellow flowers; R. calostrotum (pink), R. dichroanthum (orange), R. haematodes and R. euchroum (both brilliant red); R. Williamsianum (pink), R. campylogynum (deep purple), the tiny, plum-coloured R. myrtilloides, and lastly, the prostrate R. repens, with large, brilliant red flowers. Other plants which may find a congenial home in the bed are Pyrola rotundifolia, Shortias and Linnaea borealis.

Perennial Lobelias.—Varieties and hybrids of Lobelia cardinalis and L. fulgens, which are being wintered in frames, may be divided and the divisions planted separately. The separate portions will make good crowns for planting out at the end of April. These Lobelias delight in a moist position during summer; they will not withstand a severe winter in the open.

HARDY FRUIT GARDEN.

By W. Auton, Gardener to Viscount Elveden, Pyrford Court, Woking, Surrey.

Control of Pests.—In a short time insect life generally will take on a new lease of life, with increased activity, and nothing should be left undone at the present time which will help to frustrate these activities. Trees which are badly infested with American Blight should be gone over individually, in addition to being included in the general spraying. By means of a fairly stiff paint brush, work a paraffin emulsion or methylated spirit well into all knotty and irregular surfaces of the bark to ensure reaching all hibernating insects, and syringe the trees heavily with clear water afterwards. This pest also migrates to the roots of trees in autumn, and when it is known that a tree is affected below ground, small doses of carbon disulphide should be injected into the soil at intervals of about two feet, but keeping at least that distance away from the trunk. The last brood of the Gooseberry caterpillar hibernates in the soil and the pest emerges in early spring to continue its life cycle, hence, where this destructive pest was troublesome last season it is safe to assume that the first few inches of soil will contain numerous crysalids. The destruction of these at the present time will materially facilitate the control of the pest; where practicable, the first few inches of soil should be removed entirely and buried in the bottom of a trench. Fresh soil for making up the ground level may be brought from the vegetable quarter.

Plums on Walls and Fences.—The Plum is much appreciated amongst hardy fruits, and by a judicious selection of varieties it is possible to provide for a supply of delicious fruits for both dessert and culinary purposes over a long period. Rivers' Early ripens in July on a wall, while Coe's Golden Drop will hang until October. Although there is no necessity to afford Plums the protection of walls or fences, it is frequently easy and good practice to do so, for the more variable the sites the longer can the season be extended. Trees on fences or walls have generally more reliability of cropping, and often produce good crops when those in open positions fail. Further, it is much more easy to protect such trees from either birds or inclement weather, should the necessity arise. Fan-trained trees answer the purpose best. Cordon-training may be employed where space does not permit of fan-training, but only on walls of good height where extension of the cordons can be liberally practised, as Plums generally resent the restriction of growth which would be necessary to confine them to the space available on a low wall. The aspect for the several varieties should be chosen with care, selecting the sunniest positions for the finest dessert sorts. A southern aspect accelerates early ripening, and the additional sunshine afforded promotes flavour in the fruits, hence Kirke's, Jefferson, Denniston's Superb and Late Transparent Gage should be given such positions. For an eastern aspect Coe's Golden Drop, Rivers' Early, Victoria, President and all the Gages are suitable. For a western aspect hardy varieties not addicted to skin cracking should be chosen, such as Monarch and Pond's Seedling, while these varieties also succeed on a north wall and are sometimes useful in such positions for giving late crops.

FRUITS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Peaches and Nectarines.—Trees of these fruits growing in borders in the early house will now be swelling their crops freely, and the work of disbudding the shoots and thinning the crops will require frequent attention. To what degree this work should be carried out will depend entirely on the vigour of the tree under treatment; young shoots on vigorous trees may be removed with a liberal hand but not to such an extent as would cause a severe check to root-action. On the contrary, weakly trees should be encouraged to make new growths, also trees that have been severely root-pruned. In disbudding, first remove all shoots on the under side and those that are badly placed, preserving all the basal growths which will furnish the fruiting wood for next season. Keep a sharp watch for green or black aphis, and so soon as these pests are detected the trees should be sprayed with an insecticide or fumigated lightly on successive nights, choosing a time following a dry afternoon when the foliage is dry. Examine the borders carefully and if found to be dry they should be moistened freely with tepid water. Do not maintain high temperatures by the excessive use of fire-heat but take every advantage of solar heat. A temperature of 60° at night will suffice with a rise of 10° or more by day. The trees may be sprayed with tepid rain water once daily, in the afternoons, during periods of hot sunshine, but should the weather prove dull damping the bare spaces will be sufficient. No hard and fast rule can be laid down as to when the trees require moisture; only by close observation can this be ascertained, but as a guide trees growing in well-drained borders will need to be watered about every week during hot weather.

Successional Houses.—Trees in successional houses are in various stages of growth and should be treated as advised in various calendars for early Peaches. The trees in the latest house will be in bloom by this date; to retard the crop as late as possible the trees should be treated quite naturally, ventilating the house freely whenever possible and closing the ventilators at a much later hour than that recommended for the mid-season crop. Even when artificial heat is not used in these late houses the crop may be hastened or retarded at will by closing one at 3.30 p.m., and another at 6.30 p.m. Much will depend on the aspect of the house in this respect; presuming the house faces south-east it may be closed much earlier than one facing south-west. It is not advisable to water the borders during the time that the trees are in bloom; this should be done before the flowers open. Ventilate the house freely on every favourable occasion and, to ensure a good crop of fruit, a soft brush or rabbit's tail should be passed over the flowers about mid-day when the pollen is dry. Trees in late houses that are ventilated freely should never be allowed to lack moisture at the roots. The soil dries more quickly than in houses that are closed earlier with an atmosphere charged with plenty of moisture.

PLANTS UNDER GLASS.

By John Coutts, Assistant Curator, Royal Botanic Gardens, Kew.

Begonia Evansiana (syn. discolor).—This old Begonia (Fig. 90), which is nearly hardy, should be more generally grown for greenhouse decoration, as it is very useful towards the end of summer. Plants that have stored during the winter in a semi-dry conditions should now be starting into growth. The roots should be shaken free of the old soil and the plants placed in forty-eight-sized pots. Later, they should be shifted into six-inch or seven-inch pots. This Begonia thrives in any good potting compost, and only requires cool greenhouse treatment during all stages of its cultivation. A ready means of increase is afforded by the buds that form on the old inflorescences.

Begonia gracilis.—This Begonia which is more generally known in gardens as Begonia Martiana, may also be propagated from buds. This is a beautiful greenhouse species which should be more generally grown, and must not be confused with the B. gracilis of many continental firms, which apply the name to a section of B. semperflorens. Begonia gracilis is best started in a warm house, afterwards accustoming it to cooler conditions.

Begonia weltoniensis, B. Dregii and B. Sutherlandii.—These are all useful for greenhouse decoration. B. Sutherlandii is a summer flowering species, while B. weltoniensis and B. Dregii may be used for summer or winter flowering; old plants shaken out and re-potted at this time will flower during the late summer and autumn. Young plants raised now may be flowered during the late autumn and winter. These three Begonias are all easily grown in an ordinary greenhouse temperature.

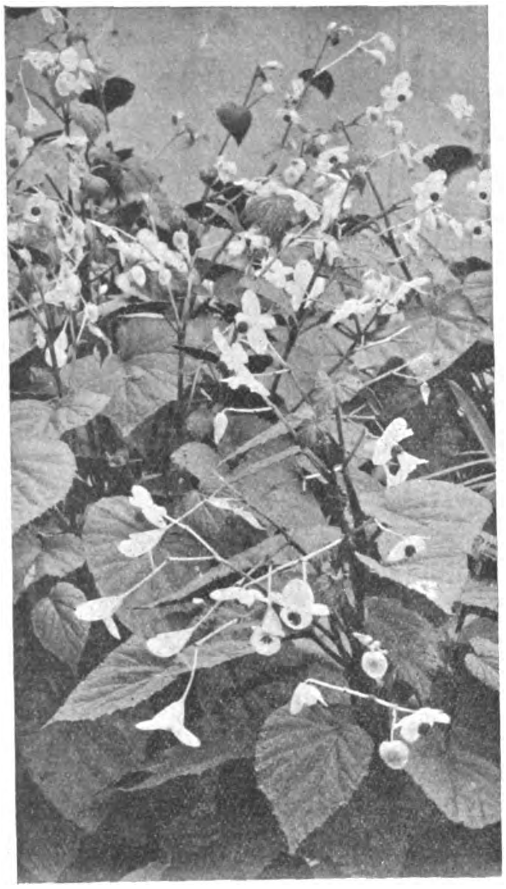

FIG. 90.—BEGONIA EVANSIANA.

Other Begonias.—Begonia President Carnot is a very fine subject for the intermediate house and is seen at its best when planted out on a raised bed of rich soil, training the shoots to wires under the roof-glass. B. Luzerna somewhat resembles B. President Carnot, but is a much stronger grower, and succeeds perfectly in the greenhouse or conservatory, making large specimens when grown on in large pots. When planted out this Begonia is an excellent subject for covering pillars. B. coccinea, when planted out, is also excellent for the same purpose, or for training to the roof-rafters. Other Begonias that are useful for the greenhouse are B. echinosepala, B. Ingramii, B. acuminata, B. fuchsioides, B. Haageana and B. glaucophylla, which makes a beautiful basket plant.

Campanula pyramidalis.—Plants raised from seeds sown last year should now be ready for placing in their flowering pots. At this date they may be stood out-of-doors at the foot of a warm wall; later, they should be plunged in a bed of ashes in an open position. Seeds should be sown now to raise plants for next year.

Capsicum annuum.—There are many fine varieties of this Solanum all of which are useful for furnishing the greenhouse during the autumn. Seed should be sown during March, in a temperature of 50° to 60°. The young plants should be potted on until they are in their fruiting pots, which should be six inches in diameter. As the season advances the plants should be accustomed to greenhouse conditions. Capsicums require good cultivation and liberal feeding during the growing season; they are very subject to attacks of Begonia mite and red spider, which must be guarded against.

FOR NORTHERN GARDENERS.

By A. T. Harrison, Gardener to the Marquis of Ailsa, Culzean Castle, Maybole, Ayrshire.

Rock Garden.—Some of the early spring flowers are making a show, and amongst these our native Saxifraga oppositifolia and its varieties are amongst the foremost; these dwarf, creeping plants are well adapted for covering the stones with a dense mat of growths, which in early spring is covered with the numerous rosy-purple and other coloured flowers. They may be increased by division soon after they have passed out of flower. Primula denticulata and its variety, P. d. alba, is always one of the first of the hardy Primulas to show colour, and where its umbels of lilac-coloured flowers are appreciated it makes a very effective group, either in the rock garden or in front of the herbaceous border. This plant may also be increased by division, as well as raised from seed.

Herbaceous Borders.—Hardy herbaceous plants are developing young growths, and if any rearranging or replanting is necessary it should be undertaken at once; the borders should first be well-manured and dug deeply so as to provide a deep root-run for the plants, for many of our hardy plants are vigorous growers, and it is only when the soil is in good condition that they produce the best results. A general renovation and replanting are not to be recommended unless the borders are in a very bad state, but a certain amount of lifting and replanting, if done systematically each year, helps to keep the borders well-furnished with healthy, vigorous specimens. Michaelmas Daisies may be quoted as an example; anyone who has observed the difference between the flowers of plants that are broken up and replanted every second or third year, and those that have been left to become crowded and exhausted will agree that there is no comparison between them. On the contrary there are many plants, such as Paeonies and Delphiniums which are best left undisturbed for a number of years to get the best results; the growths of these should be carefully thinned early in the season leaving only sufficient to form good plants without overcrowding.

Half-Hardy Annuals.—Seeds of hardy annuals should be sown now in boxes of sandy loam, covering the seeds lightly and germinating them in a moderate temperature. So soon as the seedlings are large enough to be handled they should be pricked out, either into other boxes, or better still, into cold frames in which they may be grown slowly to make good plants for bedding out later. Half-hardy annuals provide a useful range of easily-raised plants from which effective beds, as well as much useful material for cut flowers, may be annually produced, and include such general favourites as Asters (both double and single kinds), Stocks, Larkspurs, Clarkias, Cosmeas, Alonsoas and Phlox Drummondii.

Begonia Gloire de Lorraine—Plants of this Begonia and varieties of the winter-flowering type, which have been flowering since October, should now be given a rest by reducing the supply of water at the roots. Do not dry them off but keep them on the dry side for a few weeks, removing the spent flowers and foliage. When re-introduced to heat and moisture they will develop quantities of strong side shoots, which may be used as cuttings to raise a fresh batch for next winter's flowering.

TREES AND SHRUBS.

OLEARIA SEMI-DENTATA.

In his "Notes from a Welsh Garden," p. 134, Mr. A. T. Johnson reports the loss of this fine shrub by frost, and it would be of great interest to other growers if he would state what amount of frost was registered in his locality during early December, as our plants have come through the winter unharmed, including some young specimens rooted from cuttings two or three years ago and growing in an exposed situation, where 12° of frost was registered.

This is such an exceptionally fine shrub that one could only part with it if compelled to do so; moreover, it is one of the easiest of the whole family to increase from cuttings, that even where it is damaged occasionally, it would be advisable to insert a few cuttings every autumn, which, if not required for home use, would make a charming gift to an appreciative friend. In such a manner I first became acquainted with Olearia semi-dentata, and if Mr. Johnson cares to accept a young plant I will be delighted to send him one so that he may make a fresh start.

I was extremely interested to hear the story of the introduction of this shrub. The discoverer, after many days coasting round the South Island of New Zealand, and much climbing and wandering inland, secured plants and carried them to the coasting steamer. At the port of departure for this country an examination of the treasures was made, when it was discovered that only one plant had survived the ordeal by steam which had penetrated through a knot-hole in the box in which they were being conveyed home. That single specimen eventually reached this country and is probably the parent of all those now existing here, as I have not learned of the species having been reintroduced.

CORYLOPSIS SPICATA.

The great charm of this shrub is not revealed every season, but when it flowers freely during February it is a very charming plant.

The flowers are pale creamy yellow and produced in drooping clusters on the leafless branches; they are sweetly scented, and, if the flowering sprays are cut early, last fresh for a considerable time in water.

The plant was introduced from Japan to this country in 1864, and is almost as hardy as the common Hazel, to which it is closely allied, its time of flowering also synchronising with, but being distinctly superior to, the meagre catkins of our native Hazel, the petals measuring nearly half-an-inch across.

Three years since a plant of Corylopsis spicata here was specially well flowered; it measured about three feet high and about four feet through and seemed to be in perfect health, but on visiting it the next season I found it completely dead. Not a sign of the cause was to be seen, and I could only conclude that its extreme floriferousness the previous season resulted in its death. *A. T. H.*

HYPERICUM AUREUM.

This is a remarkably attractive little bush which in view of its distinctiveness and beauty might be more often planted in gardens. It does not seem to exceed about four feet in height, and it makes a shapely, twiggy shrub, often with only a single stem.

The oblong leaves, one inch to two inches in length, are a bluish green and deciduous. The flowers appear in clusters at the end of the shoots. The individual blooms, each one-and-a-half inch across, are a rich yellow, of extraordinarily heavy texture, and their centres are almost filled by the unusually large cluster of stamens.

This Hypericum is quite hardy and grows well in any free, gritty soil, in full sun or part shade. Though discovered so long ago as 1776, it is of comparatively recent introduction to this country. Many authorities, including Mr. W. J. Bean, consider it the most beautiful of all the American Hypericums. *J.*

HARDY FLOWER BORDER.

A NEW WHITE FORM OF GERANIUM ROBERTIANUM.

Some years ago the late Mr. E. C. Buxton gave me a few plants of a small, pure white Geranium which, though it is said to be a form of G. Robertianum, is quite unlike the older white variety of the latter. In fact, whereas G. Robertianum alba is such a strong grower as to be undesirable in the garden, the plant referred to has no such troublesome defect. It is very much smaller in all its parts than the more familiar plant, and its whole growth is so delicate and refined that it might easily be mistaken for a different species.

This Geranium was grown in Mr. Buxton's garden for some twenty years, and I have had it under observation for at least half that period; although it seeds freely there is no evidence of it ever having crossed with the wild red plant which abounds here. It is entirely a fresh, pale grassy-green in leaf and stem; the corolla is dead white, and not a trace of the bronze or red often seen in the common white form of the type ever occurs, not even in the fading foliage or flower.

Another feature which to my mind is very distinct, is the way in which the leaves of young, unflowered plants lie closely pressed, and spread out cart-wheel fashion on the soil. Again, I have frequently noticed the leaves of this Geranium injured by frost to which those of the Herb Robert seem entirely immune.

Mr. E. C. Buxton obtained his plants from Sir Charles Isham, who had a garden of curiosities at Menai Bridge. As most of his collection of plants came from western Ireland it is probable that this little Geranium also had its origin there. At any rate, there is not much doubt but that the whole stock of the plant now in existence in Britain came from that old garden at Menai Bridge. *A. T. Johnson.*

CIMICIFUGA.

The few species of Cimicifuga which are in cultivation are very easily accommodated in the herbaceous or mixed border, and may be recommended for their distinct appearance and graceful habit of growth. The generic name is derived from *cimex*, a bug, and *fugo* to drive away; indicating certain virtues which some species are supposed to possess.

The herbaceous perennials are allied to Actaea, and are of very easy culture in any ordinary good garden soil; a situation in half-shade is preferable, and they need a moist soil. All are easily propagated by division of the roots or by seeds.

C. racemosa is a well-known species; the flowers are white, and produced in long, compound racemes, during July and August. The leaves are triternate with serrated leaflets. This graceful plant, which grows to a height of from three to four feet, was introduced from North America so long ago as 1732. C. japonica has white, sessile flowers in very long spikes; the leaves are large, ternate, with lobed cordate segments. The plant grows about three feet high. It is a Japanese species and was introduced into this country in 1879. C. elata, with white or whitish flowers in pyramidal racemes produced in June and July, grows about two feet high. The ternate or sometimes biternate leaves are deeply serrated. This foetid plant is a native of Siberia and North America, and was introduced in 1777.

C. americana and C. cordifolia are not well-known plants; the former produces panicles of white flowers in August and September, is rather dwarf, ranging from two to three feet, and was introduced from Carolina in 1824. The latter species, similar in height but with cordate leaves, is a North American plant, and was introduced in 1812.

The Cimicifugas should be more freely used in the mixed border; they associate well with other subjects and possess a charm of their own. They are not obtrusive and thrive with the minimum of attention. *Ralph E. Arnold.*

NOTES FROM GLASNEVIN.

Since the advent of February many species of Crocus have come into flower, adding much to the interest of the garden at this early season. For sheer brilliance of colour, foremost place must be given to C. aureus, of which several groups about the rock garden are much admired for their deep golden colour. C. chrysanthus is another charming yellow species which has been flowering for some weeks; this species varies somewhat from golden yellow to paler shades and is the one from which Mr. E. A. Bowles has raised numerous seedlings. Three, or perhaps four other species, at least superficially resembling each other, are C. corsicus, C. etruscus, C. Imperati and C. versicolor. All have flowers of a lilac shade internally, the outer segments flushed with buff and showing more or less dark feathering. Mr. Bowles points out that C. versicolor shows feathering on the inner segments unlike any other spring-flowering Crocus, and his excellent *Handbook* may be consulted with much advantage by those who find it necessary to master the specific characters as revealed by the corm-tunic and spathes.

C. Imperati has proved a great success in short grass and seems to be increasing. C. Imperati albidus is equally easy to cultivate and is very beautiful. A form grown here as C. versicolor albus is indistinguishable from the white variety of Imperati. C. biflorus is one of the earliest and best, showing remarkably wide variations in colour. That which has been grown here as the type has white flowers feathered with purple on the outer segments, but I cannot distinguish between it and the two varieties known respectively as argenteus and pusillus. In C. biflorus Alexandrae, however, the broad band of dark blue or purple on the outer segments at once distinguishes this variety, which has also rather larger flowers than the type. C. biflorus var. Weldeni has flowers of similar size and shape, but pure white, except for a faint shade of purple at the base; the latter is a beautiful Crocus and worthy of being more frequently grown in gardens. Another pretty variety—C. aerius var. Celeste—which came from Daisy Hill Nursery, Newry, Mr. Bowles suspects of hybrid origin; it is pale lilac in colour but less vigorous than C. biflorus and its forms.

Crocus Susianus, a very old denizen of our gardens, still remains one of the most beautiful. The flowers are not so large as those of some other species, but the golden yellow colour of the segments internally, with the three purple stripes externally on the outer segments render it attractive whether the flowers be closed or fully expanded to the sun. C. Sieberi is a robust and satisfactory species producing flowers of pale lilac with bright orange stigmas. It increases fairly freely and may be relied on to appear annually without fail. It is said to vary from seeds but no varieties have yet appeared here. One of the earliest to flower and still in bloom is C. Fleischeri, a distinct species, the flowers with narrow white segments, the outer three striped with purple. Another lovely yellow Crocus now in flower is C. candidus var. Mountainii, and it is the only form of candidus at present in this collection. It is reputed to vary according to locality, as is not uncommon with other plants, but Mr. Mountain's variety with its deep orange flowers is a real acquisition. C. Olivieri is another desirable species, the flowers orange like the last but of a rather brighter shade. C. veluchensis has deep purple flowers and is somewhat slow to increase. The original corms of our stock were collected by the late Mr. C. F. Ball, in Bulgaria, and I take it to be the same form as that alluded to by Mr. Bowles as having been collected by The O'Mahony on Mount Rilo, Bulgaria. What seems to be the same species was received here as C. Tauri, but as this name is a synonym of C. reticulatus, which has differently shaped flowers of a generally lighter colour, it would seem that we do not possess the true species. The last species I will mention is C. Tommasinianus, and, if not the most brilliant, it can claim to be the most accommodating. In the rock garden it has spread far and wide, coming up at the side of the hardest walk and seeding into everything. However, it seems to harm nothing, and on a sunny February day makes a brave show with its starry flowers of lavender colour; the exterior of the segments is dull buff so that the flowers are most to be admired when fully open. There are numerous varieties, the most distinct here being atropurpureus.

Helleborus corsicus is a vigorous species which will grow in the most unpromising places though reaching its maximum development in good soil. The flowers, produced in panicles on long stems, are pale green and stand out most conspicuously in a shady position, for which the plant is most useful, more especially at this season. During summer the large leaves are freely produced and make an excellent ground cover among shrubs and under trees in woodland places where it might well be associated with H. foetidus.

Hyacinthus azureus from Asia Minor, figured in the *Botanical Magazine*, t. 6822, is one of the most charming of spring bulbs for the rock garden. Planted in groups here and there, especially under dwarf shrubs, its lovely spikes of azure blue are always admired. It is inclined to spread, and may occasionally crop up where not wanted, but is easily dealt with.

Iris reticulata, with its charming flowers of deep violet and gold, must always remain one of the choicest flowers of early spring. Whether in the rock garden or in narrow borders around the greenhouses it is equally happy and floriferous. Visitors occasionally enquire as to whether the clumps are ever lifted, but none of them has ever been moved since being planted; most of them have been down ten, fifteen and twenty years, and one of them ever since Sir F. W. Moore was appointed (1879); nor does position make any difference as they are just as good in the sun as shade, and in heavy damp soil as in a drier medium. Iris sindja-Reichi, a Juno Iris, and presumably a hybrid of I. sindjarensis, has been blooming for some weeks, and is still in good flower. The flowers are bright blue and held just above the grey-green, arching leaves. This Iris seems to need a good, deep soil and a sunny position, as the bulbs purchased from Messrs. Van Tubergen some years ago have increased and are now stronger than when planted. I. sindpers, of the same section, and also a hybrid with sindjarensis as one parent and persica as the other, is to be recommended for similar conditions. In this case the flowers are a shade darker but equally beautiful. The Juno Irises generally seem to like a stiff loam, a sunny position, and to be left alone. When showing signs of weakening they should be lifted very carefully in July when the leaves have ripened off and replanted at once in fresh soil, to which, especially in ground free from lime, a liberal addition of old mortar rubble should be made.

Narcissus minimus is one of the gems of the rock garden in early spring, and no flower is more earnestly looked for so soon as the year is a few weeks old. It has been in flower here since early February and rejoices in a deep but stony soil in a sunny position where it becomes thoroughly ripened in summer. N. minor, also in flower now, is, of course, larger, but equally suitable for the rock garden where the coarser garden forms are out of place. Being of stronger growth, a somewhat heavier soil suits it better.

Omphalodes verna has the delightful blue flowers of the Borage family and is now very attractive. The flowers are most freely produced in a somewhat dry position, where they are not so apt to be hidden by the leaves. Belonging to the same family, Pulmonaria augustifolia azurea is flowering freely in moister places, and especially in the bog garden.

Already the vast family of Primula has entered on its season of flowering. P. Palinuri, with large fleshy leaves and small but rich yellow flowers, has been in bloom for some time, and P. marginata is showing colour strongly. The most conspicuous group at present, however, is P. Jewel, a Juliae hybrid and the best of several. There are two forms of P. Juliae, one with small, roundish leaves and deep rosy-purple flowers, the other with larger leaves and pale, washy flowers, and I fear some of the hybrids have the latter as one parent.

Saxifrages in flower have been increasing in number since early in January. The Megasea section is best represented at the moment by S. crassifolia, a most useful plant, flourishing in any position, and flowering most freely in the poorest soil. A group planted at the base of the rockwork, right against the path, is covered with spikes of pale pink flowers, and the position is practically sunless. Other species and varieties which have been flowering for some time are S. Burseriana Emperor, S. speciosa and S. tridentina, and the hybrids S. Bursiculata, S. Faldonside and S. Paulinae. S. caucasica Desoulavyi is in full flower and is one of the best yellow Saxifragas blooming now.

Scilla sibirica and S. bifolia are in full flower and are too well-known to require further mention, but S. bifolia rosea is worthy of note for it makes a good group in the rock garden if suitably associated and kept well away from the blue form. In spite of the varietal name, the colour is not all that could be desired.

Tulips will shortly contribute to the spring display, and already Tulipa turkestanica is in flower, and although the green and white-striped flowers have no great claim to beauty, yet odd clumps about the rock garden are not without interest at this early season. T. Kaufmanniana will certainly be in full bloom ere these notes are in print.

Shrubs in flower are becoming more numerous every week. Daphne hybrida, more commonly known as D. Dauphinii, has been in flower all the winter and is quite unaffected by the hardest weather. It is an evergreen with shining, dark green leaves among which are produced the clusters of reddish purple, sweetly-scented flowers. I believe it prefers at least half shade and certainly likes a cool soil. D. hybrida is an old plant, and is figured in the *Botanical Register*, t. 1177.

Forsythias are now coming into full beauty

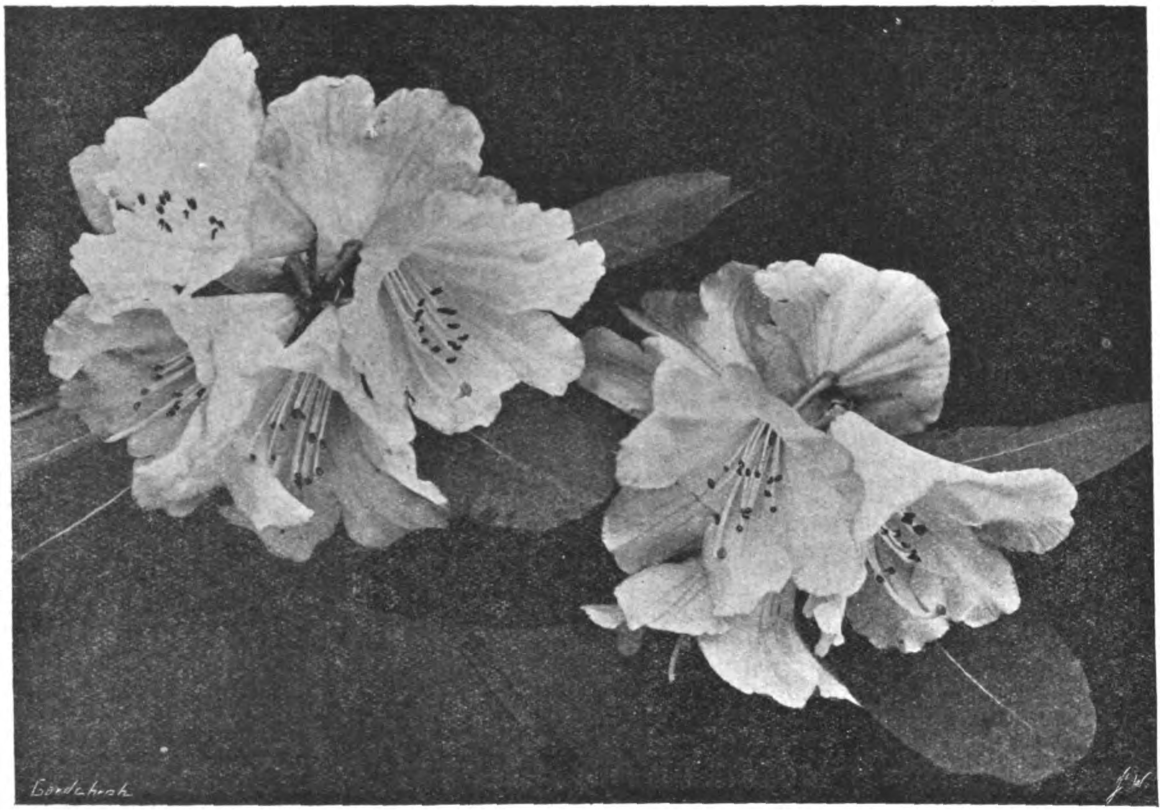

FIG. 91.—RHODODENDRON OREODOXA.
(see p. 190).

and notable among them is the little-known Forsythia ovata, native of China. Compared with the better known species and varieties the flowers are small but just as freely produced. They are clear yellow, and so far as one can judge from a young plant, the habit is more compact than that of other species. Rhododendrons continue to come into bloom, and R. praecox is at present in full glory, having succeeded R. dauricum, R. moupinense, R. parvifolium and R. Nobleanum, now over. R. Fargesii and R. oreodoxa (Fig. 91) are both in flower, and other species are promising well should the weather conditions prove favourable. *J. W. Besant, Glasnevin.*

NOTES FROM A WELSH GARDEN.

SINCE my last notes appeared in these columns the mild weather therein referred to has been maintained with the inevitable result—unseasonable, premature growth and blossoming on all sides, many subjects being fully a month before their usual date. Prunus cerasifera var. Pissardii, for example, was covered with bloom by the middle of February, Forsythia intermedia and F. suspensa, both quite in the open, were only a few days later. Osmanthus Delavayi, always so charming, opened its clusters of very fragrant, wax-white, tubular flowers at the same time, and we have experienced (perhaps to be regretted) Erica mediterranea in its several varieties in full flower at the same time as E. lusitanica (codonodes), E. carnea and other winter-flowering species.

The earlier Rhododendrons have, of course, had an exceptionally favourable time, and it looks as though R. ciliatum now (end of February) breaking bud, will be equally fortunate. R. oleifolium, presumably a form of R. racemosum, is in full bloom, and a very attractive little shrub it is. In the open woodland where these are growing, Grevillea rosmarinifolia is well-furnished with its hanging, crimson clusters; G. sulphurea is tufted with its curious cockades of old gold, and Azara microphylla is again proclaiming itself well worth growing for the delicious fragrance which its tiny flowers impart during these early days. But, in addition to this refreshing perfume, A. microphylla can always hold its own as an evergreen shrub, its leafage and habit being particularly delightful.

Familiar as they may be there is a great charm about the lesser Periwinkle (Vinca minor) at this season, especially when growing naturally under woodland trees. Of the many forms now in bloom, V. minor Bowle's variety, is noteworthy, its blossoms being unusually large and of a soft lavender-blue. A colony of selected plants gathered in the woods near Lugano also contains some very attractive forms. In some of these the widely-starred flowers of a rich, deep violet, with the segments very sharply-pointed, are singularly pretty, and, I think, uncommon.

Growing near the last-mentioned, and in striking contrast to them in colour is a group of Pulmonaria rubra, quite one of the best and most distinctive of its race, and a plant that can claim a place among the choicest of early flowers. The pale green, downy leaves, faintly spotted with a lighter shade, of this species afford an admirable setting for the bright, coral-scarlet blossoms. These have no blue or purple in them, they rise to nine to ten inches, and some of the blooms are nearly three-quarters-of-an-inch across.

The Erythroniums are, for the most part, already in bloom, and some colonies of the E. Dens-canis class, with flowers of various shades of bluish-purple and mauve, are extremely effective among the woodland Daffodils and Primroses. Perhaps the choicest of these Dog's-tooth Violets is E. grandiflorum robustum, of which the leaves are a bright, glossy, unspotted green, and the lovely flowers, on stalks nine inches high, are a full-toned butter-yellow. But the whole of these Erythroniums are irresistibly fascinating and dainty and never so much so as when growing among natural herbage.

One of the most beautiful objects in the rock garden is the little Japanese Cherry, Prunus incisa (Mame-sakura), which is said to grow on the slopes of Fujiyama. My specimen of this pigmy Cherry is about three feet high, the branches are slightly arching and wreathed from end to end with copious clusters of its pretty blossoms which are pink in the earlier stages changing to blush-white. Though quite hardy and adaptable and second to none among early-flowering rock garden shrubs, this delightful species is not often seen in gardens. This year, the plant is several weeks earlier than its usual date, and this must also be said of P. yedoensis (Yoshino-Zakura) which is already showing the colour of its rosy-tinted flowers. The latter is the popular street Cherry of Tokio, a tree of singular beauty and form.

Erodium pelargoniiflorum is always a cheerful plant on a sunny ledge of poor soil in the rock garden at this season, the first of its race to bloom, and the last to yield to autumn. It is, moreover, a most adaptable plant, doing well almost anywhere, quite hardy and producing just as many self-sown seedlings as may be useful without being troublesome.

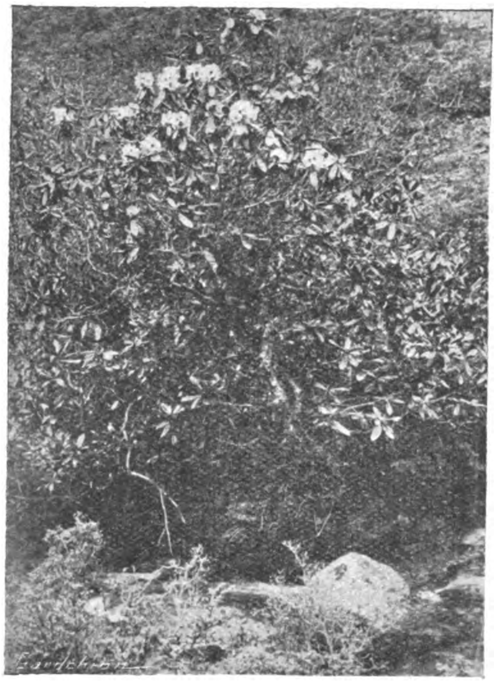

FIG. 92. 'LACTEUM' RHODODENDRON. (K.W. 5759.)

Æthionema iberideum is likewise the forerunner of its kind here, its glaucous leafage being sheeted with white flowers which smell of new-mown hay, even in a normal season, before most rock plants are awake. Anemone blanda, was rivalling the Hepaticas by the middle of February, and about the same time, appeared the lovely blues of Scilla bifolia and S. sibirica taurica, Chionodoxa Luciliae var. sardensis and C. Boissieri, this last rivalling the better-known C. Luciliae in the brightness of its colour and the clear white eye.

Sisyrinchium grandiflorum, whose large, twin bells are of the glossiest, most sumptuous purple-violet, has had a worthy companion in the snow-white variety throughout the latter days of the past month, and few plants are more strikingly dainty and refined. Primula marginata was also in full flower at the same period, and will continue for some time to come to adorn its rocky niche with its chaste lavender blossoms and beautiful foliage. Many of the old double Primroses are also coming into their best just now—mauves, purples, a yellow and a white—and these old time favourites never fail to appeal. Once we tried to grow them along our woodland walks where the native Primroses do so well, but there they were a total failure. Now, in what is more akin to an average kitchen garden soil, they are prospering abundantly.

A bold patch of colour in the rock garden is afforded by Erica carnea var. Vivellii, a rather dwarf-growing form with flowers of a very rich carmine-crimson and bronzy foliage. Another little shrub, always the earliest of its genus to flower, is Helianthemum umbellatum, whose dark green, Rosemary-like foliage makes such a telling setting for the little pure white flowers. These latter are distinctly cup-shaped, they have a slight trace of yellow at the base of the petals, and are produced in the greatest profusion practically throughout the season. This cheerful and comely shrub is still often listed as H. rosmarinifolium, a synonymous name with H. Libanotis, which has yellow flowers.

The Cardamines (syn. Dentarias) are plants one does not often see, but some of them are distinctly handsome. At the time of writing C. pratensis (syn. D. digitata) with its deeply-cut foliage and large rosy-lavender blossoms, borne on ten-inch stems, is very attractive in a cool, partly shaded woodland bed, but it has flowered this year much earlier than usual. This species is a native of mid-Europe and a very old plant in our gardens, having been introduced so far back as 1656. *A. T. Johnson, Ro Wen, Tal-y-Cafn, North Wales.*

MR. F. KINGDON WARD'S EIGHTH EXPEDITION IN ASIA.*

XXVII.—THE PICK OF THE SHRUBS.

IT is often difficult, even impossible, to assess the garden value of a plant on the spot. One is so close up to it, both in time and space, that one cannot see it in perspective, and there are many drawbacks in the conditions—weather, surroundings, company, and so on, which militate against a sound judgment. But at this distance and after the lapse of a year, one can look back on the discoveries and get a much better idea of their order of merit. I have, therefore, thought that it would be useful to add a postscript, giving the names of those plants which, in my opinion, will be the most valuable additions to our gardens, taking everything into consideration, and particularly whether the newcomer is likely to prove hardy or not.

It will be convenient to deal first with the shrubs, and Rhododendrons being the most prolific genus, I have selected the most outstanding dozen.

K.W. 5659, the pink 'Barbatum,' is in my experience unique for the colouring of its large flowers—pale rose-pink and ivory-white in broad bands—and for its loose, lolling trusses of three or four open bells. I would rank it very high, but for the fact that being a medium-sized tree, it will not flower until it is ten or twelve years old. With it I couple the somewhat similar 'Ivory Rhododendron,' K.W. 6215.

The 'Mahogany Triflorum,' K.W. 5687, though possibly only a variety of R. triflorum itself, is at its best a fine thing. Its considerable range of colouring, its tremendous hardiness, and its indifference to soil and situation, are greatly in its favour, and it is a glutton for flower.

K.W. 5732, the pink 'Thomsonii,' looks a good plant; but better still is 'Coals-of-Fire,' or the scarlet 'Thomsoni,' K.W. 5830. This last is, I believe, destined to rank as a plant for all time, and may take an honourable position at the feet of that incomparable species, R. Thomsonii.

Next, of the smaller plants, the snow-white 'Anthropogon,' K.W. 5733, is the best of its class, the obsidian green leaves, dark chocolate felt and clots of snow-white flowers, borne in unusual profusion, being valuable points; the habit, too, is unusually neat and compact. The 'Strawberry Saluenense,' K.W. 5734, another free-flowerer, is unique in colour, and being aromatic leafed, and of neat, tufted habit, will undoubtedly attract attention, especially for its anomalous foliage.

---

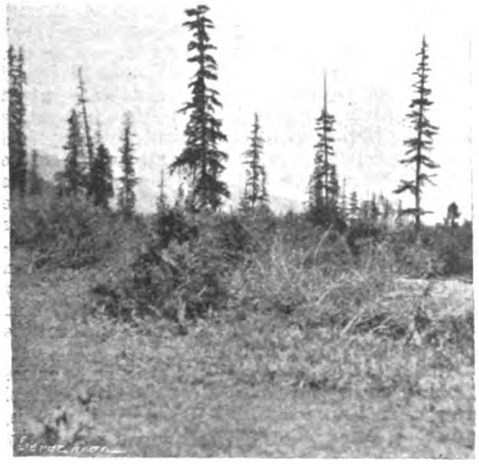

FIG. 93.—OPEN ALPINE VALLEY WITH GIANT JUNIPERS.

Home of Primula microdonta, P. Florindae, P. tibetica, etc.

Another surprising dwarf is 'Plum Glaucum,' K.W. 5843, something between a 'Campylogynum,' and a 'Brachyanthum,' remarkable for the colour of its flowers, which are almost Cherry-red. K.W. 5856 is another generous bloomer and as it may flower either in June or in October, or possibly both, it ought to be popular. Again, the flowers are of an unusual shade of pale pinkish-purple, not often seen on a dwarf. With this species I would place also K.W. 5876, another purple-flowered plant. Neither of these fit into the scheme of things, any more than does the 'Strawberry Saluenense,' with its gland-dotted leaves.

Then there is the 'Banana Trichocladum,' K.W. 5851, which cannot be omitted from the list of prize winners; it has bright flowers and many of them, while another yellow-flowered species, K.W. 5853, or 'Yellow Peril,' if not in the first flight, comes very close up by reason of its magnificent verdigris-coloured leaves, which show up brilliantly against the snow, having an almost metallic lustre. The same may be stated of 'Orange Bill,' K.W. 5874, which, in any case, ranks as high as any on account of its fine, deep, orange flower bells.

But already I have exceeded my dozen first choices, and still I have not mentioned the scarlet 'Neriiflorums,' though they are undoubtedly amongst the elite. My favourite is 'Carmelita, K.W. 5847, by reason of the large size, and brilliant hue of its flowers; but I will not deny that 'Scarlet Runner,' K.W 5845, which I saw first, more completely took my breath away. The third of the trilogy, 'Scarlet Pimpernel' has flowers of an extraordinary dark red—they are not really scarlet at all—but more the colour of dried blood. It is worth noting that of the three 'Scarlet Runner' will stand a much greater degree of cold than the other two—or does so, at any rate.

Then there is the rosy-purple 'Triflorum' ('Oreotrephes'), K.W. 5790, a cumulus of blossom hard to beat, and the beautiful, scented 'Virgatum,' K.W. 6279, with uncommonly large flowers for so small a plant; a real gem.

But I must stop. The tale of Rhododendrons which I consider absolutely first-class, perfectly hardy, and sufficiently distinct to merit the careful attention of growers has already swelled from the original dozen to which I had intended to confine myself, to half as many again, and the list might still be extended.

The genus Lonicera furnished a dozen species, of which three or four struck me as being of exceptional merit, either in flower, fruit, or foliage; sometimes, I think, in two of those attributes, but never perhaps in all three. K.W. 5822, L. Webbiana, is a small forest tree of tidy habit, growing perhaps fifteen or twenty feet high. The leaves are large and dark glossy green, but the small, dull red flowers are rather inconspicuous. Not so the Cherry-like fruits which dangle at the ends of pedicels a couple of inches long. If the birds will let it alone this ought to prove a useful, hardy, ornamental tree.

K.W. 5872 is perhaps the pick of the dozen; a somewhat untidy, straggling bush as we saw it, but no doubt capable of being decently brought up; for it must be remembered that we never saw bushes pruned in Tibet. The flowers are deep purple, not very large, but conspicuous for their unusual colour, which, seen against the young sage-green foliage and violet twigs, is startling enough. In fruit, this deciduous species is almost more notable by reason of its large plum-coloured berries, like Sloes. The plant grows in very harsh, rocky soil, and will drink as much water as it can get. Very different is K.W. 5776, which forms a neat bush, crowded with sulphur-yellow flowers enveloped in paper bracts that form a sort of skirt. The leaves are hairy and the Gooseberry-shaped fruits are bright reddish orange. I regard this species as quite in the first rank, not only of Loniceras, but of shrubs; it ought to be perfectly hardy, coming from a good all-round altitude, about 11,000 feet.

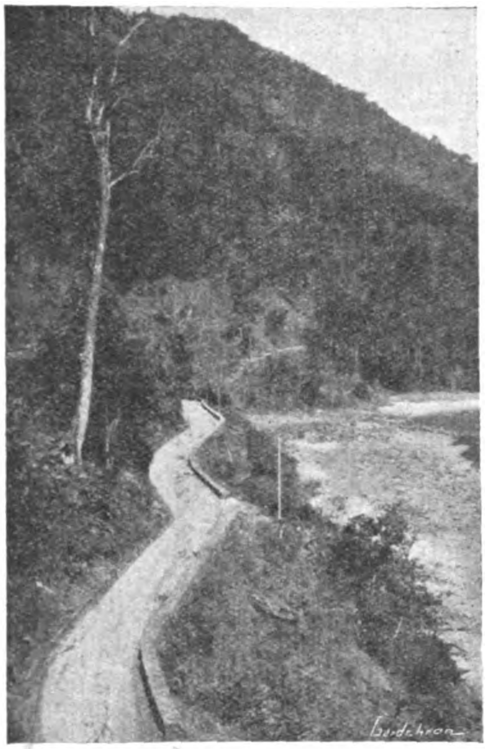

FIG. 94.—THE HIGH ROAD TO INDIA: COMING DOWN TO THE PLAINS.

Finally, there is an alpine species, K.W. 5988, similar to the last in flower, foliage and fruit, but of quite different habit; for it grows prostrate on the screes, at a sufficiently low elevation (about 14,000 feet) to have good prospects of being hardy with us. Both these are of the 'hispida' type.

Of the remaining shrubs, I doubt whether any of our Barberries, Cotoneasters, or Viburnums, of which we have such a monstrous assortment in this country, are worth bragging about. I collected a few, without feeling that the world would be the poorer if I refrained. The dwarf Barberry, K.W. 6326, was a jolly little fellow in fruit, but I did not see it in flower. K.W. 5773 is a Barberry with handsome foliage, well set-off by the black stems, and particularly attractive in its autumn suiting; and K.W. 5962 bears such a spate of blossom that it rains gold for days and days, though the crop of blue-black berries is disappointing. But there—I am ashamed to write about Barberries; it would be almost impossible to find a distinct novelty unless it had ceased to look like a Barberry at all. The same may be written of Cotoneasters—of which K.W. 6400 was, at any rate a vivid sight in fruit—Buddleias, Deutzias, Viburnums and other stock genera.

I found three Roses, the best probably being K.W. 6309; but this is drawing a bow at a venture, since I did not see it in flower. K.W. 5834 is rather like R. Moyesii, except in the colour of its flowers, and no improvement on it that I can see (the flowers are Rose-red); and K.W. 6101 is a white-flowered Sweet Briar.

Some of the dwarf Willows were handsome, but they are difficult subjects to raise from seeds, so I may well postpone reference to them. I will pass over also several other shrubs, species of Ribes, Euonymus, Caragana, Philadelphus, Prunus, Acer, Pyrus, Vaccinium, Gaultheria, Enkianthus, etc., as being of no outstanding merit that I could observe—though they may, for all I know to the contrary, develop traits which will endear them to growers—and come to two first-class plants which will undoubtedly come through the ruck and make their mark.

K.W. 5637 is, or I suppose to be, a variety of Sophora viciifolia. But Sophora viciifolia, as I have seen it in China and in England, though free-flowering, is a somewhat anaemic looking object, the pale flowers having only a tinge of violet. My plant has flowers which can only be described as rich violet, as precise a colour as could be. It grows in the rockiest, sandiest soils, or, indeed, in pure sand on the dunes in the river bed, and manages to keep alive all through the long, cold, drought of winter.

Similarly, K.W. 5774 I take to be a variety of Potentilla fruticosa, until it is proved to be otherwise. But the ordinary form of P. fruticosa with little golden buttons of flowers is quite common in the drier parts of Tibet, so this other plant from the wetter regions, with big, golden yellow blooms, at least twice the size of the others, is possibly quite distinct, though the two are very similar in habit. Anyway, K.W. 5774 is 'a winner.' It grows in the general tangle of Rhododendron and other bush which clothes the mountains at 13,000 feet, but often forms solid colonies by itself, especially in very gravelly soil, too poor or too exposed for Rhododendron. In full bloom, covered with flowers, it is a really wonderful sight, and, in my opinion, far ahead of the ordinary P. fruticosa.

These, then, are the shrubs which I should select for my own garden if strictly confined to a dozen of those we brought back from Tibet—a baker's dozen. Rhododendron, 5687, 5733, 5734, 5843, 5856, 5851, 5846, 5845, 5847 and 6279, all dwarfs, be it noted; Lonicera, 5776 and 5872; and Potentilla fruticosa variety, 5774.

With these notes I enclose four photographs which may be interesting as showing some of the vegetation and the nature of the district explored. *F. Kingdon Ward.*

FIG. 95.—WEAVING CLOTH IN A BHUTANESE VILLAGE.

EDITORIAL NOTIOES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C. 2.

Special Notioe to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed "Gard. Chron.," Rand; or by telephone, to Gerrard.* 1543.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

POTATO EELWORM.

HETERODERA Schachtii, the Potato eelworm, has been known for many years as a pest of Beets, and on the continent has been responsible for much damage. The question of a Potato race of this eelworm is at present attracting a certain amount of attention and experimental work is in progress upon the subject.

During the past few years I have frequently found eelworms present on the roots of Potatos, and have formed the opinion that they are responsible for much loss of crop. The eelworms attack the fibrous roots of the Potato, but do not appear to favour any other portion of the plant. Strachan and Taylor*, however, write: "It is a soil organism, and its attack is confined mostly to the roots of the Potato, although the tubers, also, may be attacked."

If attacked plants are examined, numerous tiny, Pear-shaped, creamy-white bodies will be found loosely attached to the root system; later in the season these tiny bodies turn darker in colour and eventually become brown and fall entirely away from the attacked plant.. The tiny bodies mentioned above are the mature female eelworms, and when in the brown stage consist of the old skin of the female filled with numerous eggs. The eelworms are just visible to the naked-eye on an attacked plant; when an infested plant is pulled out of the ground fairly early in the season many of the eelworms will be found attached to the roots. If, however, the examination is made later in the season most of the eelworms will be left behind in the soil when the plant is lifted.

I first saw an attack of this, or a similar, eelworm, in Shropshire, in the autumn of 1915, but have since found it in several parts of England. The attacks are mainly restricted to soil that is cropped frequently with Potatos, such as allotments and small gardens. Where rotation of crops is practised the pest does not cause any trouble although it is often present. Some doubt has been expressed as to whether Potato eelworms really cause a loss of crop. I believe I am right in stating that up to the time of writing there are no published data of experiments carried out under exact conditions to prove or disprove this argument. The view has been expressed that while considerable damage appeared to be caused by the eelworms to early Potatos, little or no damage was caused to main and late crop varieties. This has not been my experience. I have seen very much damage done to late Potatos for which I could find no other cause than eelworm. I remember, on one occasion, a cottager in Somerset planting an early Potato, viz., Sharpe's Express, on his allotment; after the Potatos were well above the soil they turned yellow and ceased to grow. He attributed the failure to bad "seed," and having some "seed" of Majestic left from his house garden, he planted his allotment again with this later variety. Majestic did no better than Sharpe's Express. I examined the plants of Majestic in August and all were found to be very badly attacked by eelworm. At the same time, I made an examination of many other Potato plots in the same group of allotments and found them all more or less attacked. Self-set Potatos, amongst other crops, were also attacked. I have made careful examination of most other garden crops and many weeds, but have always failed to find this eelworm on anything but Potatos.

That Potato eelworms spread gradually from one primarily affected spot, I have only one slender piece of evidence. On one occasion I saw a small garden planted with the variety Great Scot. A small Potato patch, about two square yards on one edge of the plot looked very sickly, and on pulling up the plants I found they were badly attacked by eelworms. The plants looking sickly had produced a very poor crop, but the surrounding plants, although they had plenty of eelworms on their roots appeared to be healthy, and were certainly carrying a good crop; still further away the Potatos examined showed no sign of eelworms. From this I concluded that this pest had commenced from the sickly-looking patch, and that the eelworms were gradually spreading. I further concluded that when eelworms attacked Potatos early in the season they caused sickly-looking plants and a loss of crop, but if the Potatos were attacked later in the season it was not denoted in the foliage and caused little or no loss of crop. I saw this particular plot again, a year later, and found that it was again cropped with Potatos, this time with the variety King Edward; every plant examined was affected, and the crop was a poor one.

An account of some primary experiments with eelworms carried out at Harpenden is given in an article† by Mr. A. S. Buckhurst. The object of these experiments was to determine whether the Potato race of Beet eelworm could attack other crops. Mr. Buckhurst writes: "Beet eelworm (Potato race).—A Potato plant infested with this eelworm was received from Lincolnshire in 1924 and was kept throughout the winter in a pot of damp sand (previously sterilized). In the spring, the sand was divided into seven parts and each was mixed with a pot of sterilized soil. The following seeds were planted in six of the pots: Oats, Wheat, Beet, White Mustard, Peas and Broad Beans, and in the seventh one of the tubers from the original plant was allowed to grow. In early September the plants, consisting of six each of Beets, Beans and Peas, and twelve each of Oats, Wheat and Mustard, were examined. No trace of the Beet eelworm was discerned either upon the root fibres or in the roots of any of the plants except of those of the Potato, which showed a typical attack, mature females being found on all the smaller rootlets." Later in the article, Mr. Buckhurst writes: "If, therefore, the results of these preliminary experiments prove to be well founded, it would appear that there are several crops which could safely be planted on eelworm infested land so as to avoid planting Potatos, and thus starve out the eelworms"

These experiments certainly bear out my field observations, viz., that Potato eelworms do not occur on any other plant. I have examined many other plants growing in an infested garden, *e.g.*, dwarf and runner Beans, Carrot, Parsnip, Turnip, Cabbage, Brussels Sprouts, Groundsel, Shepherd's Purse, etc.

It seems that the pest is not confined to small gardens and allotments, because in the article first referred to, the authors record experiments carried out by them on farm land in the East Riding of Yorkshire, which was heavily infested with Potato eelworm. Suggested methods of control given in this article are:—"(1) A suitable rotation of crops; (2) Potatos should not be taken two years in succession on land that has once shown signs of Potato eelworm; (3) Care should be taken not to carry the soil from infested areas to non-infested areas through such agencies as implements, Potato sets, etc.; (4) The Potatos should be cleared from the land as thoroughly as possible to prevent stray plants appearing in the intervening crops of the rotation, thus providing food for the eelworms and helping to carry on the trouble; (5) The Potatos from infested areas are usually small, and consequently, they are likely to be fed to pigs. It is not known whether "cysts" will be killed in the dungheap, therefore it would be well to take the precaution of boiling Potatos for pigs in order to destroy any "cysts" in the adhering soil. Soil from Potatos from infested areas should not be swept on to the dungheap."

Gardeners would be well advised to be on the look-out for this pest, and when present, control measures should be adopted. The pest is, in my opinion, more common than is generally supposed. *Somerset.*

EVERLASTING FLOWERS AND ORNAMENTAL GRASSES.

THE plants comprised under this heading are probably not so widely grown at the present time as they were a few decades ago. The great expansion in floriculture generally, and the national love of fresh flowers at all seasons, are probably responsible for this; nevertheless, the fact that nearly every catalogue lists them shows that there is still considerable demand for them, and there are many who think that they are as useful in the flower garden during the summer as they are valuable for the sideboard in the winter.

A few of the "everlastings" the beloved "Immortelles" of the French, are not so showy as many other summer flowers, but most of them are more or less worthy of a place in the border. Some of the most beautiful "everlastings" need greenhouse cultivation, such, for example, as Aphelexis, Phaenocoma, and some of the Statices which are more difficult to grow, and are consequently not suitable for small gardens.

One or two of the annual kinds also do better in the greenhouse, and are valuable for the decoration of the conservatory in the autumn, such as Ammobium and Gomphrena which may be raised from seeds and are easy of cultivation. Where ample space is available and considerable quantities of flowers are needed it is desirable to set apart a border expressly for them, as the flowers need to be gathered early in the season before they are fully expanded and while their colour is at its best. In smaller places a few clumps of the several varieties in the mixed border will answer the purpose.

A moderately rich soil is essential to vigorous growth, and a bountiful supply of flowers, hence, in preparing the ground for these plants moderate dressings of decayed vegetable matter should be incorporated with it. The border chosen should not be near large trees or shrubs or the plants will be deprived of their proper share of nourishment, be short-lived, and yield only a small proportion of the flowers they would produce under more favourable conditions.

Although most of the "everlastings" may be sown in the open ground in April and May they will be late in coming into flower, and consequently more difficult to dry, hence it is preferable to sow them in a cold frame or on a nearly spent hot-bed in April. Sow the seeds thinly, cover them lightly with fine soil and keep the frame close until germination takes place. The seedlings should then be gradually inured to full exposure, sheltering them only from night frosts or keen easterly winds. Towards the end of May the plants will be ready for setting out in their permanent quarters, and showery weather should be chosen for the operation. It is a mistake to plant thickly; each plant should be given ample space for its full development. As a rule, the strong growers, such as the Helichrysums, should be planted fifteen or eighteen inches apart each way, and the weaker kinds like Rhodanthes, not closer than nine inches asunder. The grasses will do well at a distance of from six to nine inches.

---

* "Potato Eelworm," by J. Strachan, M.A., B.Sc. (Agr.), N.D.A., and T. H. Taylor, M.A., Dept. of Agriculture, Leeds University. *Journal of the Ministry of Agriculture.* Vol. 32, No. 10, p.p. 941-47.

† "Notes upon Bulb Mites and Eelworms," by A. S. Buckhurst, Plant Pathological Laboratory, Ministry of Agriculture. *Journal of the Ministry of Agriculture,* Vol. 32, No. 8, p.p. 734-38.

Helichrysums are invaluable because of their hardiness and floriferous character. Of the large number of varieties in commerce none surpasses Golden Globe, Silver Globe and Fireball, all of which are very vigorous and floriferous. The several varieties of Rhodanthe are all neat in growth, very showy and particularly valuable for winter bouquets because of their clear colours. The annual Statices are amongst the most popular of "everlastings." Their light, graceful habit makes them especially valuable for room decoration, while the masses of flowers make a rich display in the border over a long period. Xeranthemums are also very showy and much prized for winter decorations.

The flowers of all "everlastings" should be gathered before they expand fully and when quite dry. It is a good plan to tie them in small bunches and hang them head downwards in a dry, airy room, as if laid flat the flower heads are apt to curve in drying, thus reducing their decorative value.

The most valuable ornamental grasses for use in conjunction with "everlastings" are Agrostis laxiflora, A. nebulosa, Avena sterilis, Briza maxima, B. gracilis, Eragrostis elegans, Hordeum jubatum, Lagurus ovatus, Pennisetum longistylum and Stipa pennata. *A. P. C.*

INDOOR PLANTS.

CHINESE PRIMULAS.

The accompanying photograph (reproduced in Fig. 96), of Primula sinensis varieties was taken on February 9 when the plants were at their best. Some of the specimens measured eighteen inches across and fifteen inches in height. A few had so many as twelve trusses of bloom open at the same time, and the others eight or nine. The first blooms appeared about a week before Christmas, and the display has continued to improve through the dull days until now. The seeds of Messrs. J. Carter and Co.'s Holborn strain were sown about the middle of April, 1925. Holborn Blue is particularly beautiful but not quite so free-flowering as other varieties, usually carrying five or six trusses of bloom. Bright Pink is very free, and its bright blooms are charming. The scarlet and the white varieties are the most profuse bloomers. No special treatment has been afforded, but we sterilise the leaf-mould used in the soil and add bone flour to the potting compost. *D. D. Robertson, Mount Clare, Roehampton.*

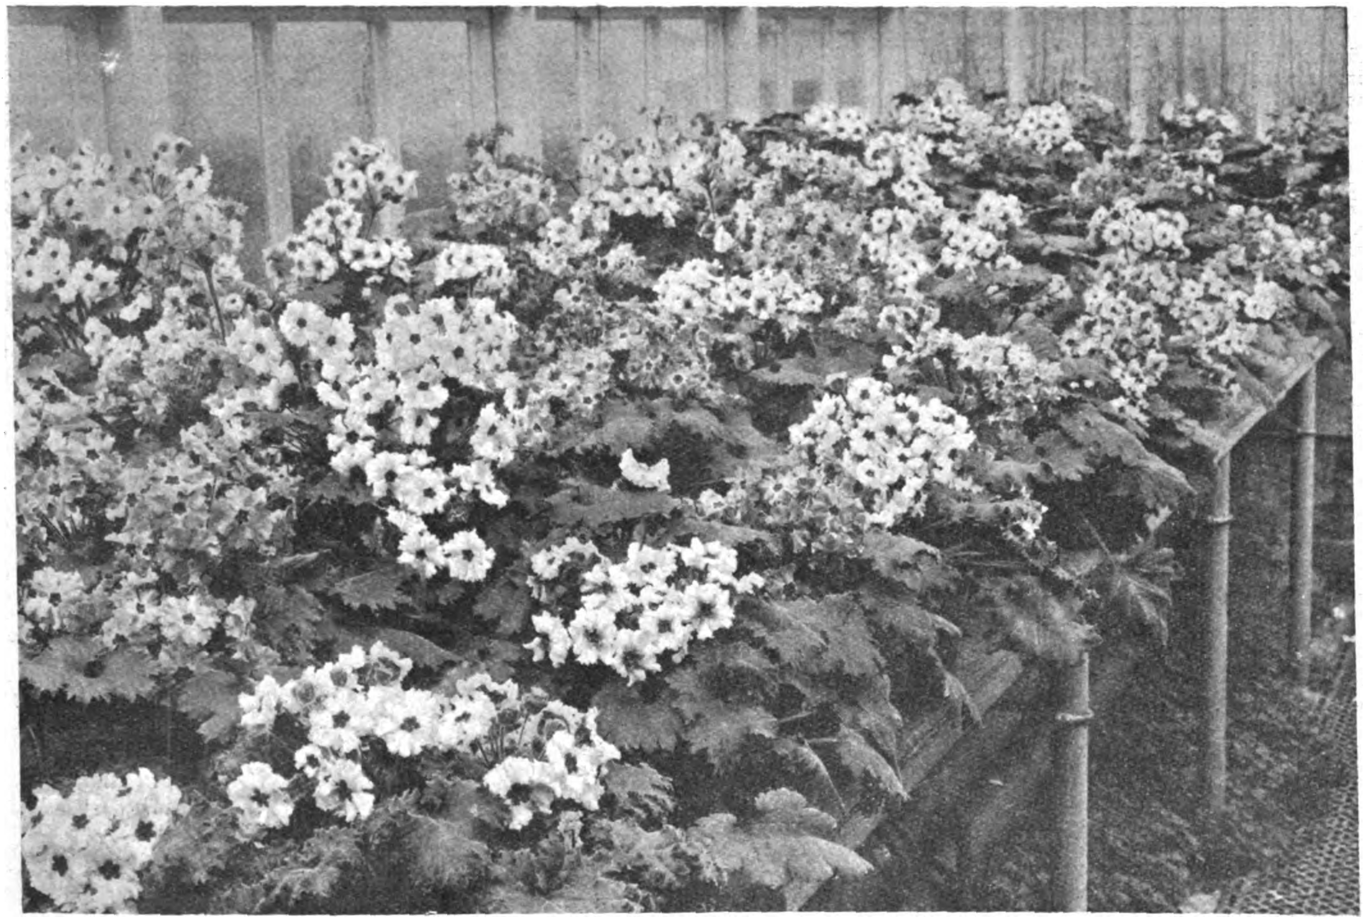

FIG. 96.—PRIMULAS AT MOUNT CLARE, ROEHAMPTON.

HIBBERTIA DENTATA.

This climber is very attractive when utilised to clothe a pillar in, or the rafters of, a cool house; the beauty of the clear yellow flowers is greatly enhanced by the rosy-brown calyces whilst the coppery foliage is not the least attractive feature of an undoubtedly good plant.

The flowers are solitary and axillary; the acuminate leaves are serrated and awned. The growth of the plant is free but not obtrusive, and it makes an ideal subject for the conservatory or cool house.

Hibbertias grow best in a compost of peat and loam mixed with plenty of sand; they are most satisfactory when growing in a border.

Propagation is effected by cuttings. H. dentata was introduced from Australia in 1814 and is illustrated in *Bot. Mag.*, tab. 2338. *Ralph E. Arnold.*

PLANTS FOR TABLE DECORATION.

The decoration of the dinner table presents no great difficulty during the summer and autumn, but in winter and spring, when cut flowers are not plentiful out-of-doors, recourse may be had to plants grown for the purpose indeed, pot plants are a welcome change even when flowers are to be had in plenty.

Many subjects may be grown and flowered well in small pots and there is a good choice of variety even in the dead of winter.

For general usefulness and good effect, Begonia Gloire de Lorraine has few superiors. Two or three batches of cuttings should be inserted at intervals of a fortnight or three weeks, thus ensuring a fresh supply of plants practically all through the winter. The best plan is to strike them singly in small thumb pots in a sandy compost. The pots should be plunged in cocoanut fibre in a propagating case and shaded from bright sunlight. When rooted, they should be taken out of the frame and grown in the house for a week or two in a temperature of 60° to 70°. With this treatment they will be ready for transferring to three-inch or four-inch pots. The compost should consist of two parts fibrous loam, one part leaf-mould, one part old cow manure, and a liberal quantity of silver sand and broken mortar rubble. The soil should be well watered. Continue to shade the plants from strong sunshine and keep the house moist by damping the floors and walls and syringing the plants overhead twice a day. If room is required in the house for other plants during summer the Begonias may be removed to a heated pit after they have rooted freely; whilst in the frames air should be admitted according to the weather. The plants should be shaded slightly at all times when the sun is strong, otherwise the foliage will become yellow. As the pots become filled with roots the latter may be fed with weak soot water, and occasionally with a little Clay's fertiliser.

As autumn approaches, return the plants to the houses for flowering, and keep the growths tied to neat stakes. The temperature of the house should not be excessively high when the plants are in flower, for excessive warmth would cause the blooms to lose their deep pink colour.

Next in order of utility and beauty are greenhouse Primulas, of which there are several kinds that may be used for this purpose. Chinese Primulas are very effective for decorating large tables, and two sowings of these plants should be made, one in May, to provide plants for use before Christmas, and the other about the middle of June to obtain stock for blooming in the New Year and onwards. The seeds should be sown in sandy soil in pots or pans, and placed in a warm greenhouse to germinate. Cover the seed pans with a sheet of glass to conserve the moisture. The soil in which Primula seeds are sown should never be allowed to become dry. The pots or pans should be examined carefully, and if moisture is required, immerse them in tepid water until the soil is soaked. So soon as the seedlings are large enough to handle, prick them off into small pots and grow them on in a warm frame for a week or so, shading them from bright sun. Water each plant only when it needs moisture. In potting these Primulas use a liberal amount of finely broken mortar rubble in the soil instead of too much sand, and also a fair amount of good leaf-mould, especially if the loam is of a heavy texture. When well-rooted, shift the plants into four-inch or five-inch pots and grow them in a cool frame where they can be lightly shaded in hot weather. In the autumn, remove them to a cool greenhouse, using just sufficient fire-heat to ward off frost and maintain a buoyant atmosphere.

Periodical applications of weak liquid manure or soot water will improve the colour of both the flowers and foliage, and here I might mention that the colours most effective in artificial light are pinks of various shades and the reds. White may be used, especially when the plants are stood on a polished table without a cloth. All shades of blue are more effective in daylight, except perhaps a very light blue.

The merits of the Stellata Primulas should not be overlooked as they are very graceful and the foliage is light and attractive.
